Genus Chrysotus, Meig.; named from χϱυσοτος, *gold colour*, bright golden green being the prevailing colour of the species.—Antennæ with the terminal joint patelliform, villose, having an inclined villose seta at the apex: eyes separated: abdomen of the male with two filiform appendages at the apex beneath: wings incumbent, somewhat spreading. Meig. iv. 40, pl. xxxv. f. 7–11.

C. *neglectus.* Hypostoma of the males minute, blackish; that of the female wider and of a whitish colour; eyes of a beautiful golden green, with light-blue reflections: forehead metallic green: body bright golden green; legs straw yellow, with dark-brown tarsi, which are yellowish at the base: halteres white: wings hyaline, with a play of colour: the terminal segment of the abdomen small, lying in a cavity of the belly, with two short threads at its extremity. Meig. *Zw.* pl. xxxv. f. 10. Found in Britain, with seven other species, all that are known to belong to the genus.

Genus Porphyrops, Meig. (Plate CCXXXVIII. figs. 20 and 20 *a.*) Generic name compounded of πoϱφυϱα, *purple*, and οψ, *the eye*. Antennæ with the terminal joint oblong, acute, the seta villose and bent downwards: eyes separated: abdomen of the male with two filiform appendages at the apex beneath: wings incumbent, parallel. Meig. *Zw.* iv. pl. xxxv. f. 1–6.

P. *diaphanus.* Male. Hypostoma narrow and black; antennæ black; forehead black above, shining white beneath: thorax metallic black with green reflections, and having a long mark of changeable white on the sides anteriorly: abdomen conical, bluish, with a silvery lustre, viewed in another direction dark slate grey; with two interrupted reddish-yellow diaphanous bands on the second and third segments: legs dark brown, with ferruginous tibiæ which are brown behind: halteres white: wings vitreous. Three lines. *Musca diaphana*, Fab. Gmel.

The female has the thorax bright golden green with light-blue reflections; the abdomen more silvery than the male; and besides the two fasciæ, there is a yellowish spot on each side of the fourth segment: the anterior thighs are yellow at the apex. Inhabits England, and is not unfrequent in woods in the south of Scotland. Twenty-nine species have been described, ten of which are ascertained to inhabit Britain. All of them are minute insects, several being only a line in length, and none exceeding the size of the species described above. They are remarkable for beauty of colouring, which generally consists of changeable tints of metallic green, blue, and silver white. This circumstance, together with the activity of their motions, by which their colours are continually presented under varying lights, renders them more observable objects, in the shade and among the foliage of woods, where they usually prevail, than might be inferred from the smallness of their size.

Genus Medeterus, Fischer. Antennæ with the terminal joint short, sub-ovate, compressed, with a two-jointed dorsal seta: eyes separated: abdomen of the male with two filets at the apex: legs elongate, slender: wings incumbent, parallel. Meig. *Zw.* iv. pl. xxxv. f. 12–17.

M. *regius.* Male. Hypostoma and palpi white: antennæ black: forehead cinereous, with a greenish lustre: thorax dark green, with a greyish patch over the middle, in which are two blackish approximating longitudinal lines: sides of the thorax cinereous: abdomen sea-green, the hinder margin of the segments with a blackish band, bordered anteriorly with grass green: legs dark green: halteres white: wings hyaline, with a brown spot behind the middle, and the anterior margin from the middle to the apex more or less dusky, the apex itself with a white spot encircled with brown.

Female. Hypostoma black, steel-blue beneath; palpi greyish black margined with white: wings hyaline, with only the brown spot, the other markings wanting. Three lines. Found in France, Holland, Austria, and England.

Genus Sybistroma, Meg. Antennæ with the terminal joint oblong, compressed, having an elongate two-jointed seta on the back, the first joint longest; eyes separated: abdomen of the male incurved at the apex, and furnished with two flat ciliated processes. Meig. *Zw.* iv. pl. xxxiv. f. 18–20.

S. *patellipes.* Male. Hypostoma rather wide, white; forehead whitish with a metallic lustre: antennæ with the two basal joints black, the third ferruginous: body obscure brassy: legs yellow, the anterior tarsi of the male orbicular, and of a black colour: halteres white; wings brown. Two and a half lines. Communicated to Meigen by Dr Leach, who found the insect in England.

Genus Dolichopus, Lat. Antennæ with the third joint trigonate, compressed; the dorsal seta pubescent: eyes separated: abdomen of the male with the apex incurved, and furnished with two membranous ciliated lamellæ: wings incumbent, parallel.

D. *ungulatus.* Hypostoma silver white, rather wide in the female, and having a protuberance on each side beneath: palpi blackish: antennæ black: forehead, thorax, and abdomen brassy green: sides of the thorax slate-grey: coxæ greyish black, the anterior pair rufous beneath: abdomen bluish grey with a play of colour, the incisures and a line on the back black: legs rufous: apex of the hinder tibiæ, and all the tarsi, black: wings slightly cinereous: halteres yellowish white: anal segment of the abdomen in the males black, with bright yellow lamellæ which are edged with black. Three lines in length. Lat. *Musca angulata*, Linn.; *Nemotelus æneus*, Degeer, *Ins.* vi. 78, 15, pl. xi. f. 14–22. Found in England, the south of Scotland, and various parts of the continent. The genus contains upwards of fifty species, none of them much exceeding three lines in length; nearly the half inhabit Britain. The larva of the one above mentioned is described by Degeer. He found it under ground in the month of May. It is white, cylindrical, eight lines in length, with a pointed or conical anterior. The head varies in form, being often sunk into the first segment. On the fourth of June it became a nymph, of a much shorter and thicker shape than the larva. It was then very restless, rolling about incessantly, with a constant movement of the abdomen. The perfect insect appeared on the 27th of the same month.

Genus Orthochile, Lat. Antennæ porrect, the third or terminal joint compressed, sub-orbiculate, and having a dorsal seta: proboscis exserted, perpendicular, with acute incumbent palpi: wings incumbent, parallel.

O. *nigrocærulea*. Thorax shining blue black, the sides of the breast slate-grey: abdomen dark metallic green; the anal segment in the males shining black: coxæ slate-grey; the thighs black, with a ferruginous apex: tibiæ rufous, the hinder pair with the half next the apex black; tarsi black: wings brown. One line. Meig. *Zw.* pl. xxxvi. fig. 5. Found in France and Germany.

FAMILY XVIII.—OCYPTERÆ.

Antennæ porrect, three-jointed: abdomen consisting of six segments: wings without a transverse nervure, pointed: proboscis concealed.

Genus Lonchoptera, Meig. (Plate CCXXXVIII. figs. 21 and 21 *a*.) Antennæ with the basal joint thickened at the apex, second cup-shaped, third sub-orbicular, compressed, with an elongate three-jointed villose seta at the apex: proboscis retracted: abdomen linear, elongate: wings lanceolate, incumbent, without transverse nervures. Meig. *Zw.* iv. pl. xxxvi. f. 6–13.

L. *tristis*. Forehead dusky black; wings smoke colour: under side of the head yellow: thorax shining black, the sides yellow: abdomen black, the terminal segment of the males with yellowish lamellæ: legs yellow; the hinder tibiæ somewhat clavate, stouter in the male than in the other sex: halteres white. Has been taken by Dr Leach in England, and occurs in the vicinity of London. *L. lutea*, known by its yellow colour, and a narrow black line along the whole length of the back, has recently been observed in Dumfriesshire and some other southern counties of Scotland.

FAMILY XIX.—SCENOPINII.

Antennæ deflexed, three-jointed; the third joint truncated and without bristles: proboscis concealed: abdomen consisting of eight segments.

Genus Scenopinus, Lat. (Plate CCXXXVIII. figs. 22 and 22 *a*.) Antennæ sub-deflexed, three-jointed, the lower joints small, third elongate, sub-cylindric, truncated, without a seta: proboscis retracted and concealed: abdomen linear, flat, eight-ringed: wings incumbent, parallel.

S. *vitripennis*. Head glossy black: body black; thorax with a faint metallic lustre: halteres brown: head white beneath: legs yellowish red: wings hyaline. One and a half line. Not common. Near Moffat.

FAMILY XX.—CONOPSARIÆ.

Antennæ porrect, three-jointed, angular at the base proboscis porrect, geniculated: thorax without a transverse suture: abdomen consisting of five or six segments halteres naked: wings incumbent. Meig. *Zw.* iv. xi.

Genus Conops, Linn. (Plate CCXXXVIII. figs. 23 and 23 *a*.) Antennæ approximating, the first joint cylindric, second and third clavate, the apex with a two-jointed style: proboscis standing out, filiform, geniculated at the base: ocelli wanting: wings incumbent, parallel.

C. *flavipes*. Antennæ black; head rufous, with a reddish-brown inflated vesicle on the crown, in front of which there is a black line; from this a black vitta extends to the antennæ, where it becomes wider, but does not reach the margin of the eyes: thorax deep black, with a yellow spot on each shoulder, and another on each side behind under the base of the wing: scutellum black, margined with yellow: abdomen sub-cylindric, slightly clavate behind, black; the second and third segments in the male, and the fourth also in the female, with a bright yellow band behind; the basal segment with a yellow spot on each side; the two terminal ones ash-grey: halteres rufous: legs yellow; thighs black, yellow at the base; apex of the tarsi brown: wings with the anterior margin more or less brownish. Five lines. *C. flavipes*, Linn.; *C. macrocephala*, *Samou. Comp.* pl. ix. fig. 8. Upwards of twenty species have been described as belonging to this genus, only six of which have been ascertained to inhabit Britain. They are usually found on flowers, and seldom occur in large numbers. The individual described is found not unfrequently in the south of England, and occurs sparingly during the autumn in Roxburghshire, and the neighbourhood of Edinburgh, generally on the flowers of *Senecio Jacobæa*.

Con. melanocephala of one of Meigen's earlier works was merely a specimen of the above in which the head had become black.

It appears that the females of these insects deposit their eggs in the larvæ of humble-bees (*Bombus*), or even in the bodies of the perfect insects. Latreille, indeed, has frequently observed them issue from the abdomen of the latter. MM. Lachat and Audouin presented a memoir to the *Société Philomatique*, on an apodal larva which they found in the month of July, in the interior of *Bombus lapidarius*, and which they deemed the larva of *Conops flavipes*.[1] Bosc seems to have also noticed this parasite, but he mistook it for an intestinal worm properly so called.[2]

Genus Zodion, Lat. Antennæ with the basal joint cylindric, second clavate, compressed at the base, third ovate, the back with a style: ocelli three: proboscis standing out, filiform, elongate, geniculated at the base: wings parallel, incumbent.

Z. *cinereum*. Hypostoma pale reddish yellow, the margin of the eyes white, the latter colour extending half way up the forehead: forehead reddish yellow anteriorly, passing into dark brown above: antennæ black, the third joint rufescent, with a blackish apex; sometimes the second joint is likewise rufescent anteriorly: thorax cinereous, with four blackish longitudinal lines on the back, of which the two central ones are abbreviated, the sides and hinder part spotted with black: abdomen cinereous,

---

[1] See *Mém. de la Soc. d'Hist. Nat.* t. i. p. 330, pl. xxii.

[2] *Diction. Class. d'Hist. Nat.* t. iv. p. 404.

the incisures from the second to the fourth marked with a cross row of elevated black points; the back sometimes with four blackish evanescent spots: anal segment of the males shining black: legs cinereous, the tarsi blackish: wings somewhat brownish, slightly ferruginous at the base. Three lines. Meig. *Zw.* iv. pl. xxxvii. figs. 6, 7; *Myopa cinerea*, Fab.; *Zodion conopsoides*, Lat. Usually found on umbelliferous flowers. It is an inhabitant of England, France, and various parts of the continent of Europe.

GENUS MYOPA, Fab. Antennæ with the basal joint cylindric, second clavate, compressed at the base, third globose, with a dorsal style: ocelli three: proboscis standing out, filiform, elongate, geniculated at the base and middle: wings incumbent, parallel. Meig. *Zw.* iv. 140.

M. *buccata.* Hypostoma white, without spots; forehead dark brown, with grey spots; antennæ testaceous, third joint reddish yellow: thorax spotted with black and cinereous: shoulders testaceous: scutellum dark brown: abdomen testaceous or reddish brown, spotted with grey on the sides: legs testaceous; thighs blackish before the apex: tibiæ with a dark-brown ring at the middle, and another at the apex; tarsi rufous: wing-scales white: halteres pale yellow; wings clouded with pale brown, the small cross nervure not darker coloured. Meig. iv. 142. *Conops buccata*, Linn. Occurs at times on umbelliferous flowers, in gardens and fields, throughout England and the south of Scotland. Botanic Garden, Edinburgh. *M. picta*, which does not differ much from the above, is likewise found in similar situations near Edinburgh.

FAMILY XXI.—STOMOXIDÆ.

Antennæ deflexed, three-jointed, obtuse beneath: third joint with a dorsal seta: proboscis porrect, geniculated: abdomen consisting of four segments: halteres covered with a double wing-scale. Meig. *Zw.* iv. xi.

GENUS SIPHONA, Meig. Antennæ with the lower joints small; third elongate, linear, obtuse; the base with a naked dorsal seta: proboscis exserted, horizontal, filiform, geniculated at the base and middle: wings divaricating. Meig. *Zw.* iv. 154.

S. *tachinaria.* Thorax and scutellum pale cinereous; the abdomen nearly conical, pale ferruginous; the first and second segments pellucid at the sides, the incisures whitish, with small wart-like spots: thorax, scutellum, and abdomen of the females likewise pale ferruginous; the latter elliptical, and the sides not so clearly pellucid; legs ferruginous, with brown tarsi. Two lines. Meig. *Zw.* pl. xxxvii. fig. 25; *Stomoxys cristata*, Fab. Inhabits Europe. Has been found in England, but is very scarce.

GENUS STOMOXYS, Fab. (Plate CCXXXVIII. figs. 27 and 27 *a*); from στομα, *the mouth*, and οξυς, *sharp.* Antennæ incumbent, with the lower joints small; third elongate, compressed, linear, obtuse, with a dorsal seta at the base; proboscis standing out, horizontal, geniculated at the base; wings divaricating.

S. *calcitrans.* Hypostoma yellowish white: proboscis stiff, porrect, shining black beneath, with filiform, short, ferruginous palpi: forehead wide with a black line, somewhat narrower in the males than in the females: antennæ brown, with a seta which is plumose on one side: thorax cinereous, with short hairs and a black line along the back: abdomen rounded, covered with short hairs, cinereous, with shining black spots: legs black brown: wing-scales white: wings uncoloured. Three lines. *Conops calcitrans*, Linn.; Degeer, *Ins.* vi. 39, 11; *Musca pungens*, pl. iv. fig. 12–18. Not unfrequent throughout Britain. This is the common well-known stinging-fly, which, in hot and sultry summer days, persecutes men and beasts with its painful bite. It attacks the legs in preference to any other part of the body. Even horses and cattle are not protected by their thicker hides. It is said to be most annoying before a storm. The *C. calcitrans* is so like a common house-fly, as to have induced the erroneous belief that the latter is also a blood-sucker. The females lay their eggs in dunghills. According to the observations of MM. Lepelletier and Serville (*Encyclop. Méth.*), many individuals survive the winter in a state of torpidity,—twenty having been sometimes found together in a mass, within the hollow of a tree.

FAMILY XXII.—ŒSTRACIDES.

Antennæ small, three-jointed; the third joint with a naked seta: mouth closed up, without a distinct proboscis: abdomen pubescent, consisting of four or five segments. Meig. *Zw.* iv. xi.

GENUS ŒSTRUS, Linn. (Plate CCXXXVIII. figs. 24 and 24 *a.*) Antennæ with the lower joints minute, the third globose, with a naked seta: mouth closed:[1] halteres covered: wings spreading, the apex with a transverse nervure.

Œ. *ovis.* Hypostoma flesh red: forehead dusky red, with a reddish line, and blackish depressions: antennæ black: thorax cinereous, sprinkled with small blackish warts, each of which supports a fine hair; on the neck these warts form lines: scutellum pale brown, with blackish warts placed without order: abdomen arched, rounded, obtuse, silky white, with a yellowish play of colour in some places, and prettily sprinkled with irregular spots of a deep shining black: legs pale red: wing-scales large and white: wings clear hyaline, with a blackish transverse nervure at the middle. Five lines. Meig. *Zw.* pl. xxxviii. fig. 16; Linn. Fab.; Réaumur, *Ins.* iv. *Mém.* xii. tab. xxxv. fig. 10–15; Clark, *Linn. Trans.* iii. tab. xxiii. fig. 14–17. Of the nine European species of Œstrus, as now restricted, only three inhabit Britain, viz. the one above described, and *Œ. pictus* (Curtis, *Brit. Ent.* iii. pl. cvi.), and *Bovis*. *Œ. ericetorum* of Dr Leach is not regarded by Meigen as essentially distinct from that last named.

The injury and annoyance which the insects of this genus, familiarly known under the names of breeze, gad-fly, &c. cause to sheep and cattle, render them deserving of our careful consideration. Mr Bracy Clark, to whom we still owe the best account of their economy,[2] procured, about the middle of June, some full-grown larvæ of *Œ. ovis*, from the inside of the cavities of the bone which

---

[1] Meigen's expression, *mund geschlossen*, is obscure. It has in fact been doubted whether the insects of this and the following genus had any mouths. Linnæus says, "Os nullum punctis tribus;" but, according to Mr Bracy Clark, when the hairs, which in all the species greatly obscure the oral organs, are removed, two clavated *palpi* are seen, and between the opening of the mouth;—"and by laying open the vesicular or inflated part of the face, the continuation of it is visible in the form of a membranous *haustellum*, which is generally coloured with some dark-brown matter lodging on the inside; though I confess, after repeated dissections, I have not been able to trace this haustellum farther than the inside of the inflated part of the head, where it appears to enlarge and terminate. Fabricius has minutely described labia to the haustellum, and other apparatus to the mouth, which I have not been fortunate in obtaining a sight of. At the same time I cannot help being surprised that he should have overlooked the *palpi*, which he expressly denies the existence of, though tolerably visible even without the aid of glasses." (*Linn. Trans.* vol. iii. p. 322.)

[2] *Observations on the Genus Œstrus, Linn. Trans.* vol. iii. p. 289; see also the author's later work, *An Essay on the Bots of Horses and other Animals*, 4to, 1815. It is quoted and referred to by a recent French writer under the title of "The Bost of Horse!"

supports the horns of the sheep. They were nearly an inch long, of a delicate white colour, flat on the under side, and convex on the upper; having no spines at the divisions of the segments of the body, though provided with tentacula at the smaller end. When young they are entirely white, but as they increase in size their upper side becomes marked with two transverse brown lines on each segment, and some spots become visible upon the sides. They move with considerable quickness, holding with the tentacula as a fixed point, and drawing up the body towards them. There is a broad line of dots on the under surface, which appear as rough points under a microscope, and probably serve both for locomotion, and for exciting such a degree of inflammation in the membrane on which they rest, as to cause the secretion of lymph or pus. Mr Clark has usually found these larvæ in the horns or frontal sinuses, though he has remarked that the membranes of those cavities were scarcely at all inflamed, while those of the maxillary sinuses were highly so. From this he is led to suspect that they inhabit the maxillary sinuses, and crawl, on the death of the animal, towards the horns and frontal sinuses. In common with *Œ. Bovis*, they do not seem confined to any particular season, for young and old are found together at the same time. When full grown they fall through the nostrils, and change to the pupa state, lying on the earth, or adhering by the side to a blade of grass. The fly bursts the shell of the pupa in about two months.

The manner in which the perfect insect lays its eggs is difficult to determine, owing to its obscure colour and extremely rapid movements. The great agitation of the sheep also interferes with accurate observation, but its general motions and method of defence leave little doubt that the eggs are deposited on the inner margin of the nostril. "The moment," Mr Clark observes, "the fly touches this part of the sheep, they shake their heads, and strike the ground violently with their fore feet; at the same time, holding their noses close to the earth, they run away, looking about them on every side, to see if the fly pursues; they also smell to the grass as they go, lest one should be lying in wait for them. If they observe one, they gallop back, or take some other direction. As they cannot, like the horses, take refuge in the water, they have recourse to a rut, or dry dusty road, or gravel pits, where they crowd together during the heat of the day, with their noses held close to the ground, which renders it difficult for the fly to get at the nostril." Mr C. imagines that the last-named part, from the constant attacks, and the consequent rubbing upon the ground, becomes inflamed and painful, which occasions their touch to be so greatly dreaded by the sheep.

The *Œstrus Bovis*, in the perfect state, is a very beautiful insect, and one of the largest of the European species. The wings are without spots; the abdomen has a central band of black, and is clothed at the extremity by reddish-yellow hairs. Although its effects on cattle have been often remarked, yet the fly itself, as Mr Clark has observed, is rarely seen or taken, "as the attempt would be attended with considerable danger." It inflicts greater pain in depositing its eggs than any other species. "When one of the cattle is attacked with this fly, it is easily known by the extreme terror and agitation of the whole herd: the unfortunate object of the attack runs bellowing from among them to some distant part of the heath, or the nearest water, while the tail, from the severity of the pain, is held with a tremulous motion straight from the body, in the direction of the spine, and the head and neck are also stretched out to the utmost. The rest, from fear, generally follow to the water, or disperse to different parts of the field. And such is the dread and apprehension in the cattle, of this fly, that I have seen one of them mee the herd when almost driven home, and turn them back, regardless of the stones, sticks, and noise of their drivers; nor could they be stopped till they reached their accustomed retreat in the water. When oxen are yoked to the plough, the attack of this fly is attended with rea danger, as they become perfectly uncontrollable, and wil often run with the plough directly forwards, through the hedges, or whatever obstructs their way." The attack of this small but dreaded foe has indeed been often described, and by none with more of taste and accuracy than b the "Mantuan Bard."

> Est lucos Silari circa, ilicibusque virentem
> Plurimus Alburnum volitans, cui nomen Asilo
> Romanum est, Œstron Graii vertere vocantes:
> Asper, acerba sonans: quo tota exterritu sylvis
> Diffugiunt armenta; fusit mugitibus æther
> Concussus, sylvæque et sicci ripa Tanagri.[1]

The female deposits her eggs with great rapidity, and does not remain above a few seconds on the back of the animal. The larvæ live beneath the skin, between it and the cellular membrane, in a proper sack or abscess, rather larger than the insect. When young they are smooth, white, and transparent, become darker as they increase, and when full grown are of a deep-brown colour. After a time they work their way out, fall to the ground, and assume the state of chrysalis, in which they continue from about the latter end of June till towards the middle of August, when the perfect insect makes its appearance.

GENUS GASTRUS, Meig.; *Œstrus*, Linn.; *Gasterophilus*, Leach. (Plate CCXXXVIII. fig. 25, 28, and 28 *a*.) Antennæ with the lower joints small, the third compressed and furnished with a naked dorsal seta: mouth closed: halteres naked: wings without a transverse nervure at the apex. Meig. *Zw.* iv. tab. xxxviii. fig. 18–23.

G. *Equi*. Head with fine hairs, yellowish grey, the forehead rather darker, with two reddish-brown vittæ: antennæ ferruginous: thorax anteriorly with ferruginous pubescence, that on the hinder part of a darker colour, the sides with rather long glistening hairs passing into whitish yellow: scutellum with black pubescence behind: abdomen ferruginous, the pubescence fine, with a silky gloss; the back with a triangular blackish spot on each of the segments, and sprinkled with several small spots, at least in the male: legs and halteres ferruginous: wing-scales white: wings whitish; having a waved brownish-grey band across the middle, and two spots of the same colour at the apex: the ovipositor of the females is thick, cylindrical, and of a shining black colour. Five lines. Meig. *Zw.* iv. pl. xxxviii. 21, 22; *Œs. Bovis*, Linn.; *Œ. Equi*, *Linn. Trans.* iii. 298, pl. xxiii. f. 7–9.

Not common in Britain. This species, likewise known by the name of breeze or gad-fly, usually frequents elevated heathy districts, and we have observed it flying about the summits of the Westmoreland hills,[2] and those of Roxburghshire. Mr Bracy Clark has also furnished us with some valuable information on the manners and metamorphosis of this insect, the larvæ of which are commonly called *bots*. "The mode pursued by the parent fly to obtain for its young a situation in the stomach of the horse is truly singular, and is effected in the following manner:—When the female has been impregnated, and the eggs are sufficiently matured, she seeks among the horses a subject for her purpose, and approaching it on the wing, she holds her body nearly upright in the air, and her tail, which is lengthened for the purpose, curved inwards and upwards: in this way she approaches the part where she designs to deposit the egg, and suspending herself for a few seconds before it, suddenly darts upon it, and leaves the egg adhering to the hair: she hardly appears to settle, but merely touches the hair with the egg held out on the projected point of the abdomen. The egg is made to adhere by means of a glutinous liquor secreted with it. She then leaves the horse at a small distance, and prepares a second egg, and, poising herself before the part, deposits it in the same way. The liquor dries, and the eggs become firmly glued to the hair: this is repeated by various flies till 400 or 500 eggs are sometimes placed on one horse. The horses, when they become used to this fly, and find it does them no injury, as the *Tabani* and *Conopes*, by sucking their blood, hardly regard it, and do not appear at all aware of its insidious object."[1] The inside of the knee is the part usually chosen, although other places are sometimes selected. It is worthy of note, however, that these ova are always laid where they are most liable to be licked off by the horse's tongue. It is not, however, precisely the eggs themselves which are conveyed into the interior of the animal. Mr Clark found that after they have remained four or five days on the hairs, they became *ripe*,—after which the slightest application of warmth and moisture is sufficient to bring forth the latent larva in an instant. "At this time, if the tongue of the horse touches the egg, its *operculum* is thrown open, and a small active worm is produced, which readily adheres to the moist surface of the tongue, and is from thence conveyed with the food to the stomach." Mr Clark has often clipped off some hairs with eggs on them, and holding them in his hand, moistened with saliva, has seen them hatched in a few seconds. If the larvæ pass the dreadful ordeal of mastication, and are transmitted uninjured to the horse's stomach, they attach themselves to every part of it, but are generally most numerous about the *pylorus*. Sometimes, but much less frequently, they occur in the intestines. Their numbers are very various,—from half a dozen to above a hundred. They generally hang in clusters, being fixed by the small end to the inner membrane of the stomach, to which they adhere by means of two small hooks or *tentacula*. When removed from the stomach they will attach themselves to any loose membrane with which they may come in contact, and even to the skin of the hand. On attaining to their full size, they pass by the intestinal canal, drop to the ground, and enter the chrysalis state. Upon the whole, Mr Clark does not regard these insects as hurtful to horses, but rather views them favourably, as natural *stimuli*. Valisnieri, however, considered them as the cause of the epidemic malady which in 1713 carried off so many horses in the territories of Mantua and the Veronese.[2]

---

[1] *Georg.* lib. iii.

[2] On one occasion particularly, on crossing some hill pasture above Elleray, the seat of Professor Wilson, we were suddenly attacked by three of these insects. They flew round about us in a state of angry excitement, coming sometimes within a few inches of the face, and keeping so close to each other, that, having the forceps in hand, we captured the whole three at once, to their great surprise, and probably disappointment.

Four other species are found in Britain, besides the one to which the preceding observations more particularly apply,—viz. *Œ. hæmorrhoidalis, nasalis, Clarkii*, and *salutiferus*.[3]

FAMILY XXIII.—MUSCIDES.[4]

Antennæ inclined, three-jointed, obtuse beneath: the third joint with a seta on the back: proboscis concealed, geniculated at the base: thorax with a transverse suture: abdomen having from four to six segments. Meig. *Zw.* iv. xi.

GENUS XYSTA, Meig. Antennæ incumbent, shorter than the hypostoma, second and third joints nearly equal, compressed; the terminal one with a naked dorsal seta at the base: mouth with a mystax: abdomen convex, consisting of five or six segments: wings divaricating.

X. *cilipes*. Hypostoma and forehead greyish white, the last with a black line: palpi ferruginous, the apex brown: thorax dark grey, with three blackish lines: abdomen shining black, consisting of six segments; the two terminal segments grey, the apex having a shining black bent appendage: legs black, strong: the hinder tibiæ arched, dilated, and fringed with long black bristles: wing-scales white; halteres slender, black: wings hyaline, yellowish at the base. Three and a half lines. Meig. *Zw.* iv. 182, pl. xxxix. f. 5.

Two species only belong to this genus, both of which appear to be scarce on the continent, and neither of them has been observed in Britain.

GENUS PHASIA, Lat. Antennæ incumbent, shorter than the hypostoma, third joint rather longer than the second, obtuse; the base with a naked dorsal seta: mouth villose: abdomen depressed, pubescent, consisting of five segments: wings divaricating. Meig. *Zw.* iv. pl. xxxix. f. 6–16.

P. *subcoleoptrata*. Hypostoma whitish, with a pearly play of colour; forehead white, with a changeable dark grey line; antennæ blackish brown; thorax light grey, with four black lines, the two central ones abbreviated behind: scutellum cinereous: abdomen oval, flat, black brown in the male, with cinereous, and sometimes reddish-brown reflections, the apex golden yellow: that of the female black brown, with a dark dorsal line: wing-scales of the male brownish, of the female white: legs blackish: wings of the male broad, yellowish at the base, the anterior margin having a brown vitta extending rather beyond the middle, and there is another of the same colour along the centre, which is dilated at the apex so as to appear somewhat curved forwards; wings of the female comparatively narrow, hyaline, somewhat yellowish at the base. Male four, female three lines. Meig. *Zw.* iv. 190, pl. xxxix. f. 13.

Occurs in the northern parts of the continent of Europe and in Britain, but appears to be rare. *P. hemiptera, semicinerea*, and *pusilla*, are the only other kinds hitherto found in Britain, although the genus contains upwards of thirty species.

GENUS GYMNOSOMA, Meig.; from γυμνος, *naked*, and σωμα, *the body*. Antennæ with the second and third joints nearly equal; the terminal one compressed, linear, obtuse; with a naked dorsal seta at the base: mouth naked: abdomen nearly naked, globose, consisting of four segments: wings spreading. Meig. *Zw.* iv. pl. xxxix. f. 17–22.

[1] See *Linn. Trans.* vol. iii. p. 298; and the Essay mentioned in preceding note.

[2] *Ragionamento intorno all' Œstre de Buoi.* Opere, t. i.

[3] Stephens' *Systematic Catalogue*, part ii. p. 296.

[4] The tribe Muscides of Latreille (excepting, we believe, the genera *Diopsis, Scenopina*, and *Achias*) has been recently created into a separate order, named MYODARIÆ, by M. Robineau Desvoidy. See an abstract of his views in the *Diction. Class. d'Hist. Nat.* t. xi. p. 365.

G. *rotundata.* Male. Hypostoma straw-colour, silky: forehead golden yellow, with a brownish vitta changing into red: antennæ black; the third joint ferruginous on the inner side at the base; thorax dull-ferruginous, with four brownish longitudinal lines, and a shining black transverse band behind: scutellum black: abdomen ferruginous, pellucid, with black spots on the back: legs black: wings brownish, ferruginous at the base: wing-scales dirty white.

Female. Hypostoma and forehead pearl-white; the frontal vitta brown: thorax cinereous on the sides and beneath. Four lines. *Musca rotundata*, Linn. Fab.; *Ocyptera rotundata*, Lat. On flowers and shrubs: found near London, and on the continent, not unfrequently.

Genus Ocyptera, Meig. (Plate CCXXXVIII. figs. 26 and 26 *a*.) Antennæ somewhat deflexed, third joint longer than the second, linear, compressed, obtuse, having a naked dorsal seta at the base: mouth furnished with a mystax: abdomen elongate, cylindric, subsetose, four-ringed: wings spreading. Meig. *Zw.* iv. pl. xxxix. f. 23–29.

O. *brassicaria.* Hypostoma and forehead silky white, the former with two narrow black lines, the latter with a broad black vitta: antennæ blackish: thorax anteriorly slate grey, with four black lines, the two in the centre narrow: abdomen with the first and second segments sanguineous, the former with a large triangular mark of black on the back, the two terminal segments black, the penultimate one silvery on the anterior margin: legs black: wing-scales pale white: wings brownish grey, the base ferruginous. Five to six lines. Meig. iv. 211, pl. xxxix. f. 29. Apparently a scarce species. It occurs near Edinburgh.

M. Leon Dufour, in a memoir on the insects of this genus, has shown that the larvæ of two species, *O. cassidæ* and *bicolor*, are parasitical,—the first in the visceral cavity of *Cassida bicolor*, the second in that of *Pentatoma grisea.* Each feeds upon the epiploon or fatty matter of his host.[1]

Genus Lophosia, Meig. Antennæ deflexed, the two basal joints minute, the third very large, compressed, triangular, with a naked dorsal seta at the base: mouth with a mystax: abdomen cylindric, composed of four segments: wings spreading. Meig. *Zw.* iv. pl. xl. f. 1–4.

L. *fasciata.* Hypostoma silky white; antennæ with the two first joints black, the third brown: thorax bristly, shining black above, dark grey on the sides, with a changeable cinereous spot on each shoulder: abdomen sub-cylindric, arched, slightly narrowed at the base, bristly, of a shining black colour, the anterior margin of the second and third segments changeable white: thighs black, somewhat pubescent, bluish white beneath, with a naked white spot on the inner side at the apex; anterior tibiæ blackish brown, posterior rufous: tarsi black: wings hyaline, with a broad obsolete cross band of a brownish colour before the apex. Five lines.

This genus is readily distinguishable from all the allied genera by the large and distinctly trigonate terminal joint of the antennæ. It contains but one species, which occurs on the continent.

Genus Phania, Meig.; named from φανος, because most of the species are pellucid. Antennæ deflexed, third joint elongate, linear, compressed, obtuse; the base with a naked dorsal seta: mouth with a mystax: abdomen consisting of four segments, the apex elongate, and bent inwards: wings spreading. Meig. *Zw.* iv. pl. xl. f. 5–10.

P. *curvicauda.* Head silver white, with a black play of colour: palpi and antennæ black brown; the third joint with a finely pubescent seta, thickened at the base; forehead with a deep black line, broadest in the female: body shining black, bristly, except on the shoulders, where there are white spots: wing-scales white: halteres black brown; wings brownish grey, the base yellowish: legs black. Meig. iv. 221, pl. xl. f. 10. Rare: it occurs in Britain along with two other species, *P. vittata* and *thoracica.*

Genus Trixa, Meig. Antennæ incumbent, short; second and third joints equal, terminal ovate, having a naked dorsal seta at its base: hypostoma villose, without a mystax: wings spreading, with a transverse nervure at the apex. Meig. *Zw.* iv. pl. xl. f. 11–16.

T. *dorsalis.* Hypostoma cinereous; palpi and antennæ black brown: thorax ash grey, with four black lines: scutellum black: abdomen rufous, having a broad dorsal line of black, which at the base of the segments changes with a play of colour into whitish grey; the third and fourth segments have a similar play of colour on the sides; wing-scales white: wings greyish; the small cross nerve of the middle rather thick, black, edged with brown: legs black; tibiæ and tarsi faintly rufescent. Five lines. Inhabits Britain, but is scarce. Only one other species of the six described by Meigen is known to be British,—*T. variegata*, which has occurred in the neighbourhood of London, in Dumfriesshire, and near Edinburgh.

Genus Miltogramma, Meig. Antennæ incumbent, third joint elongate, linear, compressed; the base with a naked dorsal seta: mouth setose: wings spreading, the apex with a transverse nervure. Meig. *Zw.* pl. xl. f. 17–26.

M. *fasciata.* Hypostoma white, with flesh-coloured play of colour: palpi and antennæ clear reddish yellow; the frontal vitta rather broad: thorax and scutellum cinereous, with three black lines: abdomen conical, the first segment black, the following white anteriorly, and banded with black behind; on the sides the white passes with a play of colour into brownish red: legs black: wing-scales white. Four lines. Meig. iv. 227, pl. xl. f. 26.

The males have been found in Germany, the females are unknown.

Genus Tachina, Illig. Antennæ deflexed or incumbent, the third joint truncated beneath; the base with a naked dorsal seta: mouth with a mystax: wings spreading, having a transverse nervure at the apex. Meig. *Zw.* iv. 234, pl. xl.

T. *grossa.* Head ferruginous, with a brown frontal line changing into ferruginous; palpi ferruginous, with black bristles; antennæ blackish brown at the base; second joint ferruginous, third sub-quadrate, brown with a yellowish play of colour: seta black: body shining black: wing-scales dark brown: wings greyish, the base ferruginous: legs black. Eight lines. Meig. iv. 239. *Musca grossa*, Linn.; *Echinomyia grossa*, Lat. Found occasionally in most parts of Britain. We took it in Sutherland. It is one of the largest of the European Diptera. The larva lives in the dung of cattle, and is described by Réaumur. We may observe that the genus Tachina, notwithstanding the labours of recent writers, is still a great magazine of ill-assorted species. Considerably above three hundred occur in Europe.

Genus Gonia, Meig.; from γονια, *an angle*, referring to the form of the antennal seta. Antennæ deflexed, incumbent, the third joint elongate, prismatic, the base with a naked seta, which is three-jointed and geniculate:

---

[1] *Annales des Sciences Nat.* t. x. p. 248. See also *Règne Animal*, t. v. p. 513.

Diptera Proboscideæ.

eyes remote: wings spreading, the apex with a transverse nerve.

G. *capitata.* Head reddish-yellow, with a whitish play of colour; palpi ferruginous; antennæ dark brown; the second joint ferruginous: thorax blackish, passing into brown on the back, with an ash-grey play of colour, and marked with four black lines; scutellum brownish yellow: abdomen pellucid, ferruginous, shining, with an indistinct dorsal line of black; the first and second incisures have a very narrow, and the third a wider edge of changeable whitish yellow: belly ferruginous; legs black: wing-scales white: wings somewhat grey, with the base yellowish. Six to seven lines. *Musca capitata*, Degeer, *Ins.* vi. 12, 2.

This genus is of limited extent, not including more than a dozen species. Two of these, besides the above, occur in Britain, but are by no means common. *G. capitata* seems to be most plentiful in Sweden.

Genus Zeuxia, Meig. Antennæ incumbent, the second and third joints equal, the third or terminal one compressed and obtuse, having a plumose dorsal seta at the base: mouth with a mystax, and clavate projecting palpi: wings spreading, the apex with a transverse nerve.

Z. cinerea. Hypostoma white: forehead wide, bristly, white with a small black line: palpi extended horizontally, large and clavate, ferruginous; antennæ brown: thorax bristly, having a suture across the back, the colour pale grey, with four black lines anteriorly, and three behind, the central ones much narrower than those at the sides: abdomen bristly, conical, four-ringed, and of an ash-grey colour changing into brown: legs black: wing-scales large, the halteres covered: wings nearly hyaline. Three lines. Has been found in Germany.

Genus Idia, Meig. Antennæ incumbent, the third or terminal joint oblong, having a dorsal seta at the base, plumose on one of the sides: palpi projecting, clavate: wings with a transverse nerve at the apex.

I. *fasciata.* Hypostoma shining black, spotted with white, and not furnished with a mystax: antennæ shorter than the hypostoma, and of a brown colour: thorax ash-grey, the colour playing into black, with three broad lines of black down the middle: scutellum grey, with a blackish play of colour: abdomen oval, black, with three rufous interrupted bands: belly yellowish red: legs black: wing-scales white, entirely covering the halteres: wings greyish. Three lines. Has been found at Marseilles, and on the hills near Frejus, but is very rare.

Genus Mesembrina, Meig. The generic term is a Greek word signifying meridian. Antennæ incumbent, the third or terminal joint oblong, prismatic, having a plumose dorsal seta at the base: body hirsute: wings spreading, and furnished with a transverse nerve at the apex.

M. *meridiana.* Hypostoma black, with a large angular spot of a bright gold colour on each side: forehead shining black, with a dull black streak: palpi black: antennæ dark brown, the seta ferruginous at the base: body and legs shining black; the two last joints of the anterior tarsi brown in the males, all the onychii yellow: halteres brown: wing-scales, and likewise the base of the wing, ferruginous. Six lines. *Musca meridiana*, Linn. Fab. Common throughout Britain during the summer and autumnal months, on flowers and in woods—often seen resting on the stems of trees.

The larva of this species lives in cow-dung. It is yellow, conical, and composed of many segments. At the mouth or narrowest end it has only one hook, and four short fleshy horns or warts. The hinder end or anus is, as it were, four-cornered and truncated, and has two circular brown spots, which are slightly raised, and are each perforated by a single air-hole. The two anterior air-holes are placed on the sides of the first segment. The larva changes itself in its own skin into a dark-brown nymph, which is nine-cornered behind, or nearly circular, and the posterior air-holes are observable. In summer the fly appears in a few weeks, but the nymphs formed late in the season continue throughout the winter, and produce the perfect insect in the spring.

The species of this genus are not regarded as generically distinct by Latreille, but form part of his genus *Musca*, or *Mouches proprement dites.*

Genus Sarcophaga, Meig. Named from σαρξ, *flesh*, and φαγω, *I eat.* Antennæ incumbent, the third or terminal joint oblong, prismatic, the base with a plumose seta, naked at the apex: eyes not united: wings spreading, and furnished with a transverse nerve at the apex. Meig. *Zw.* v. 14, pl. xliii. fig. 1–10.

S. *mortuorum.* Head silky golden yellow, with a reddish play of colour; palpi ferruginous; antennæ fulvous, changing into whitish grey; line down the forehead reddish brown, changing into golden yellow: thorax blackish, with a grey play of colour, and black lines: abdomen shining steel blue; belly and legs black: wing-scales white: wings greyish. Five to six lines. *Musca mortuorum*, Linn. Fab. Frequent in the south of Scotland, in England, and apparently throughout the north of Europe, except Germany, where it is said to be rare.

In this genus the eggs are not unfrequently hatched within the body of the mother, which has induced their being regarded as viviparous,—strictly, *ovoviviparous.* Of this kind is the *S. carnaria* (*Musca carnaria*, Linn.), a species somewhat larger than the common flesh-fly (*M. vomitoria*). The female deposits her living larvæ on meat, carcasses, and even on wounded or diseased subjects of the human race.

Genus Dexia, Meig. Antennæ incumbent, the third or terminal joint elongate and compressed, with a densely plumose seta at the base: abdomen conical (in the male) or oblong-elliptical (in the female): wings spreading.

D. *compressa.* Hypostoma of a shining silvery hue, with a black play of colour; forehead shining black, with a deep-black vitta; palpi rufous; antennæ nearly the length of the hypostoma, slender, the seta with a short plume: thorax bluish grey, with two wide shining black lines, which are continued over the grey scutellum to the sides: abdomen somewhat compressed on the sides, shining rufous, with a blackish line on the back spotted with grey; the incisures bright silver white, with a play of colour; legs black, with rufous thighs: wing-scale large and white: wings with a marginal spine, brown, clouded, and yellow at the base. Four to five lines. *Ocyptera rufa*, Fab.; *Musca rufiventris*, Fallen. Rather scarce: has been found in Germany, Spain, England, and some other parts of Europe. Twenty-four species are referred to this genus, fourteen of which seem to be indigenous to Britain.

Genus Musca, Linn. Antennæ incumbent, the third joint elongate, obtuse, compressed in a prismatic form, the base with a plumose dorsal seta: abdomen ovate, setose: wings spreading, the apex with a transverse nerve.

M. *maculata.* Male. Hypostoma white, with a brown play of colour; forehead white, with a blackish vitta, which becomes narrow above; palpi black: thorax whitish, with four broad black lines, the two central ones united behind the cross suture, and drawn over the scutellum in the form of a lozenge; the scutellum having a black spot on the side: abdomen globose, grey, with a light testaceous-red play of colour, and several deep black spots of different form and size: legs black; wing-scales dirty white: wings somewhat brownish.

Female. Forehead wide, whitish, with a deep-black double vitta: thorax light grey, the lines narrower than in the male: abdomen light grey, rarely inclining to testaceous; the spots and other characters as in the other sex. Four lines. *Musca maculata*, Gmelin. Degeer. *Ins.* vi. 41, 13. In summer and harvest in hedges and on flowers; not rare. It is frequent in Roxburghshire during the autumn on the flowers of *Senecio Jacobæa.* Many of the insects of this genus are very common. *M. Cæsar*, distinguished by its brilliant golden-green colour, and *M. vomitoria*, commonly called the *flesh-fly*, are abundant on carcasses throughout Europe. The common house-fly, *M. domestica*, is remarkable for its extensive distribution, being found in Pennsylvania, New Orleans, and other parts of the new world.

We may observe in regard to the last-named species, that it is subject to a singular disease, of which the cause is not yet known. A white crust forms upon the abdomen, which becomes greatly distended, and the segments become distant from each other, so as to produce a ringed appearance. In this condition it is frequently found dead, adhering to walls, and sometimes to the stalks or leaves of plants. Its body is at this time filled with a fatty matter, which has been observed to have exploded on all sides through the pores.

Genus Anthomyia, Meig.; from ανθος, *a flower*, and μυια, *a fly*. Antennæ deflexed, the third or terminal joint oblong, compressed, obtuse, the base with a plumose, pilose, or naked seta; the frontal vitta obscure, narrowed above in the male: mouth with a mystax: abdomen consisting of four segments, setose: wings spreading or incumbent, without a transverse nerve at the apex.

A. *Angelicæ.* Hypostoma and forehead white, the former with a blackish play of colour: thorax bright grey in the male, inclining to ferruginous in the female: scutellum and abdomen ferruginous, the last without a brown play of colour; the black dorsal line does not extend to the hinder extremity, and in the female it is usually interrupted on the third segment: legs rufous, with brown tarsi. Four lines. *Musca Angelicæ*, Scop. *Ent. Cariol.; Musca deceptoria*, Gmel. Schrank. Abundant in woods in the south of Scotland, and apparently equally plentiful in England.

The genus Anthomyia contains upwards of two hundred European species, more than the half of which have been found in Britain. In addition to the one described above, we may name two other well-known species of the genus *A. meteorica* and *pluvialis*, Linn.

Genus Drymeia, Meig. Antennæ deflexed, the third joint oblong, compressed, obtuse at the apex, with a pubescent dorsal seta at the base; forehead with an obscure vitta; the eyes of the male united: mouth with a mystax: proboscis slightly projecting, the capitulum oblong, and furnished with a hook: abdomen four-ringed, setose: wings incumbent, parallel, without a transverse nerve at the apex.

D. *obscura.* Hypostoma white, with a blackish play of colour; antennæ half the length of the hypostoma, black; thorax shining black, bristly, with a cross suture; that of the female inclining to grey, and having two indistinct longitudinal lines of a dark colour: abdomen rather long, bristly, ash-grey, with spots and a line along the back of changeable black; flat in the male, arched in the female, and acute behind: wing-scales small and white: halteres black: legs of the same colour: wings somewhat brownish. Three to four lines. Found in August and September, not unfrequently, in many parts of the continent. Another insect, presenting generic characters somewhat similar to the above, has been found in England, and is named *D. hispida:* some doubt, however, attaches to the propriety of referring it to this genus.

Genus Eriphia, Meig. Antennæ incumbent, the third joint oblong and compressed, the apex obtuse, and having a naked dorsal seta at the base: mouth very hirsute: eyes of the male united: abdomen four-ringed, the apex very hirsute in the male: wings without a transverse nerve at the apex.

E. *cinerea.* Male. Hypostoma grey, shining white on the sides; forehead black, changing into grey; antennæ black: thorax bristly, rather glossy black, with a faint grey play of colour, and marked with three black lines: abdomen with the first segment black, the following three ash-grey, having a dark-brown play of colour, and a black line on the back; the second and third with a black band behind: wing-scales small, yellowish: halteres black: wings somewhat brownish: legs black. Four lines. Found by M. Baumhauer at Genisberg.

Genus Dialyta, Meig. Antennæ incumbent, the length of the hypostoma, the third joint long, compressed, obtuse at the apex, with a naked dorsal seta at the base: mouth with a mystax: eyes equally remote: abdomen four-ringed, pilose: transverse nerve at the apex of the wing wanting.

D. *erinacea.* Hypostoma silky white, with a black play of colour; forehead shining black, with a deep black vitta changing into whitish grey; palpi black, bristly; the antennæ likewise black: body shining black; thorax somewhat hoary, having two scarcely perceptible longitudinal lines, and a distinct prominence on the shoulders: abdomen of the males rather long, elliptical, flat, arched, somewhat greyish, the incisures and a line on the back black, but very faintly marked; that of the female oval, pointed, much arched, and shining black: wing-scales white; halteres black: wings broad, ferruginous at the base: legs black. Three to four lines. A rare species, the native country of which is not yet known.

Genus Coenosia, Meig. Antennæ incumbent, the third or terminal joint long, linear, compressed, with a seta at the base, which is either plumose, or pubescent, or naked: mouth with a mystax: eyes distant, those of the male somewhat approximating: abdomen four-ringed, setose, clavate at the apex in the male: wings incumbent, without a transverse nerve at the apex. The insects of this genus, which is of considerable extent, are found in hedges and on flowers, the smaller kinds are most abundant among grass. With the exception of the species described below, we are not acquainted with their habits and metamorphoses.

C. *fungorum.* Hypostoma white, changing into brown; forehead black, the hinder part of the head ash-grey; palpi and antennæ black, the seta of the last distinctly plumose: thorax grey, with four black lines, which, however, are often indistinct: abdomen rather long, rufous; sometimes with a brownish dorsal line: legs rufous, with black tarsi: wing-scales and halteres white: wings somewhat clouded. The scutellum is sometimes ferruginous, as well as the shoulders. Three and a half lines. The larva of this insect lives in mushrooms, is four and a half lines long, of a whitish-grey colour, with two hooks on the head, the hinder part thick and obtuse. It undergoes its metamorphosis in the earth.

Genus Lispe, Meig. Antennæ incumbent, the terminal joint elongate, compressed, obtuse at the apex, and having a plumose seta at the base: eyes distant: palpi somewhat projecting, slender, spoon-shaped at the apex: abdomen ovate, four-ringed: wings incumbent.

L. *tentaculata.* Male. Hypostoma silky whitish yellow; the frontal vitta wide, and blackish grey; palpi of a shining silvery hue, with a yellow play of colour: thorax greyish black, with dark indistinct longitudinal lines: abdomen flat, ovate; the first segment grey, the following black; the second and third segments with a rounded white spot on the back, and another on each side of a triangular form placed at the anterior edge; the fourth having only the two triangular spots: legs black; the anterior tarsi have the first joint somewhat shorter than the second, and black, the rest yellowish; wing-scales and halteres white; wings rather grey.

Female. Hypostoma bright yellow; the spots on the abdomen grey; the legs wholly black, the tarsi all alike. Three lines. *Musca tentaculata*, Degeer. Found in Germany, and various other parts of the north of Europe. In Britain it has occurred near London, and seems to be the only species of the genus belonging to this country.

Genus Cordylura, Fallen. Antennæ deflexed, the terminal joint oblong, compressed, truncated at the apex, the base with a seta, which is either plumose or villose: head sphæroidal, the hypostoma scarcely descending, and furnished with an imperfect mystax; eyes distant, globose: abdomen five or six ringed, that of the male linear and clavate at the apex; wings incumbent, parallel, the length of the abdomen.

C. *pubera.* Hypostoma white; palpi black: antennæ shorter than the hypostoma, black, with a plumose seta: forehead of the male not so wide as that of the female, black, with a greyish-white play of colour, sometimes changing anteriorly into reddish yellow: body bristly, shining black; thorax with a line of changeable white in the middle of the front: the sides of the thorax changing into bluish white: wing-scales and halteres white: wings rather dull, the base and anterior margin ferruginous: thighs black, the tibiæ and tarsi testaceous, the latter in the male spotted on the under side with black. Four lines. *Musca pubera*, Linn. Fab. Meig. *Zw.* pl. xlv. fig. 22, *female.* Of occasional occurrence in the southern parts of England.

Genus Scatophaga, Meig.; from σκατος, *dung*, and φαγω, *to eat.* Antennæ deflexed, the terminal joint elongate, prismatic, obtuse, the base with a seta, which is either plumose or naked; head spheroidal, the hypostoma descending, and furnished with a mystax: eyes distant, rounded: abdomen five-ringed, linear in the male: wings incumbent, parallel, much longer than the abdomen.

S. *scybalaria.* Hypostoma, antennæ, and frontal vitta rufous, the latter very wide; palpi whitish; thorax brownish yellow, with obsolete lines: abdomen brownish yellow, that of the male thick, and clothed with rufescent hairs; legs ferruginous, pubescent; wing-scales small and yellow: halteres yellow: wings large, ferruginous, with brown nervures, the transverse nerve in the middle black, and usually a little bent. Five lines. *Musca scybalaria*, Linn. Fab. This species is of frequent occurrence in Britain. *S. stercoraria* and *S. merdaria* are among our most common insects, and most of the species described by Meigen, amounting to fifteen in number, are inhabitants of this country.

Genus Dryomyza, Fallen. Antennæ incumbent, approximating, the third or terminal joint oblong, obtuse, prismatic, with a villose seta at the base: head spherical; the hypostoma descending, coarctate, naked, blunt below: eyes remote, rounded: abdomen oblong, five-ringed: wings incumbent, very much longer than the abdomen.

D. *flaveola.* Light ferruginous, shining: hypostoma bright yellow, especially on the sides; antennæ black brown, with a dark-yellowish base, and a long black pubescent seta: thorax with two brownish approximating lines on the back; on the abdomen are likewise four brownish lines, but these, properly speaking, are the interior vessels shining through: legs ferruginous, becoming brownish at the extremity: halteres clear yellow; the wings hyaline. Five lines. *Musca flaveola*, Fab. Not rare in Britain, nor in most other parts of Europe.

Genus Sapromyza, Fallen. Antennæ deflexed, the third or terminal joint oblong, compressed, obtuse at the apex, the base with a seta, which is either shortly plumose or villose: head sub-hemispheric, the hypostoma somewhat descending, naked, flat: eyes distant, rounded; abdomen oblong, five-ringed: wings incumbent, parallel.

S. *rorida.* Entirely pale yellow, the seta of the antennæ short and plumose: hypostoma and incisures of the body whitish: wings of a yellowish tint. Two lines. Found during summer, not unfrequently.

Genus Ortalis, Fallen. Antennæ deflexed, oblique, the third or terminal joint oblong, compressed, and having a naked seta at the base: hypostoma arched in the middle, naked; the forehead hirsute; eyes oblong; abdomen five-ringed: wings erect (vibrating).

O. *vibrans.* Hypostoma and forehead very bright orange yellow, with the margin of the eyes whitish: antennæ rufous, with a finely pubescent seta: body shining bluish black: halteres white: wings hyaline, the first longitudinal nerve thick, and of a black colour; the apex of the wing occupied by a triangular blackish-brown spot: legs black. Two and a half lines. *Musca vibrans*, Linn. Fab. Degeer. Don. x. 54, pl. cccxlvi. fig. 3. *Tyrophaga vibrans*, Curtis, *B. E.* fol. 126. This insect, which forms the genus *Seioptera* of Kirby, is of frequent occurrence throughout England and the southern district of Scotland. It is rare in Germany, but is plentiful in Sweden and most other northern countries.

Genus Sepsis, Fallen. Antennæ incumbent, the terminal joint oblong, obtuse, compressed, with a naked seta at the base: head globose; the hypostoma flat, and furnished with a mystax; eyes rounded, distant: abdomen four-ringed, petiolate, sub-cylindric, naked: wings erect (vibrating). These lively little insects, which are in constant motion, are found on bushes, in hedges, and among grass, almost everywhere, and are for the most part very common from the first bright warm days of spring to the end of harvest: they probably continue during winter. Their natural history is not known.

S. *cynipsea.* Head shining black; antennæ brown: body shining black, with metallic lustre: legs black; anterior coxæ yellow, the thighs black; tibiæ rufous, inclining to testaceous; and in the hinder legs the base of the thighs is rufescent. One and a half line. *Musca cynipsea*, Linn.; *Micropeza cynipsea*, Lat. Common in England and the south of Scotland. In the vicinity of Edinburgh *S. cylindrica* is common, and we have likewise observed *S. nigripes*, *S. violacea*, and *S. punctum.*

Genus Cephalia, Meig. Antennæ incumbent, the third joint elongate, compressed, gradually attenuated, with a pubescent dorsal seta at the base: hypostoma descending, naked; the proboscis standing out: eyes distant, rounded: abdomen four-ringed: wings . . . .

C. *rufipes.* Hypostoma testaceous; forehead black; palpi black; antennæ blackish brown, rufescent at the base: body black, naked: sides of the thorax, breast, and scutellum testaceous: halteres white, not covered; scarcely a trace of the wing-scales is perceptible; legs slender, testaceous: wings hyaline, the first longitudinal nerve thick and black, the apex with a brown spot. Has been found at Berlin and in Austria.

Genus Lauxania, Lat. Antennæ projecting obliquely, remote, the third or terminal joint elongate, compressed, obtuse, with a shortly plumose seta at the base: hypostoma somewhat descending, impressed in the middle: eyes remote, oblong: abdomen ovate, five-ringed: wings parallel, incumbent.

L. *cylindricornis.* Shining black; eyes during life green, with four purple bands; antennæ projecting straight forwards, longer than the head, dark brown, with a whitish pubescent seta; hypostoma shining black, with the lateral edge glistening white; forehead with a dull-black vitta: wing-scales and halteres black; legs black, the hinder tarsi yellow; wings yellow, black at the base. One and a half line. *Sargus cylindricornis*, Fab.; *Musca chrysoptera*, Schrank. Frequent in summer among grass and brushwood.

GENUS LONCHÆA, Fallen. Antennæ incumbent, approximating, the third or terminal joint oblong, compressed, obtuse at the apex, and having a naked seta at the base: hypostoma flat, somewhat descending, naked: eyes oblong, the forehead of the male narrow, of the female wide: abdomen ovate, villose, six-ringed: wings incumbent, parallel.

L. *nigrimana.* Male. Antennæ brown, shorter than the hypostoma, the third joint ovate, flat: forehead flat, dull black: body shining greenish black: wings pale yellow: legs black: the middle and hinder tarsi rufescent. Two lines. Found in the vicinity of London, along with eight other species of this genus.

GENUS TRYPETA, Meig. (Plate CCXXXVIII. fig. 29.) Antennæ incumbent, approximating, the third joint oblong, compressed, obtuse at the apex, and having a seta at the base which is either naked or pubescent: hypostoma somewhat descending, flat, naked: eyes somewhat rounded, distant; the forehead wide and setose: abdomen five-ringed, the apex obtuse in the male, but furnished with a projecting style in the female: wings erect (vibrating).

T. *Zoë.* Honey-yellow, shining, the metathorax bright black: the wings of the male have two dark-brown spots at the anterior border, the smaller one lying above the small cross nerve, and having a small branch projecting forwards from behind; the other, which is much larger, occupies the apex, extending scarcely beyond the fourth longitudinal nerve: in the female the wings have a large brown spot before the middle, and another at the apex, with a narrow cross band, sometimes interrupted, at other times indistinctly marked, in the space between. Male one and a half, female two lines. In the neighbourhood of Edinburgh, and near Jedburgh; not common.

Several different names have been bestowed on this genus. It is named *Traupanea* by Schrank, and *Tephritis* by Latreille: the latter seems to be most generally adopted. To this genus belongs the insect which, in the Isle of France, is so destructive to the lemon crop, by depositing its eggs in that fruit. Its multiplication is sometimes extreme.

GENUS TETANOPS, Fallen. Antennæ small, distant, projecting obliquely, the third joint ovate, compressed, the base with a naked dorsal seta: hypostoma reclined, descending, carinated, naked; forehead projecting, flat, naked: abdomen five-ringed, the style of the female incurved and jointed.

T. *myopina.* Hypostoma and forehead greyish white; antennæ reddish yellow: thorax light grey, the scutellum of a similar hue: abdomen in the male with the two first segments light grey, unspotted, the two following shining black, having the hinder margin and a line on the back grey, the fifth entirely black; in the female it is light grey, with a black spot on each side of the segments: legs reddish yellow; wings hyaline, with light-brown spots and black transverse nerves. Two to three lines. This seems to be a rare insect. It has been found in England.

GENUS PSILA, Meig. Antennæ deflexed, oblique, somewhat remote, the third or terminal joint oblong, compressed, obtuse at the apex, and having a villose dorsal seta at the base: hypostoma reclined, flat, naked, descending: eyes remote, rounded; forehead naked: abdomen six-ringed, the style of the female jointed and acute: wings incumbent, parallel, the first longitudinal nerve simple.

P. *Rosæ.* Shining black, slightly glossed with brassy: head rufous; forehead occasionally with a black longitudinal line; palpi yellow, the apex black: antennæ rufous, the apex blackish, the seta white and pubescent: legs bright yellow; halteres white; wings hyaline. Found in May and September in England and elsewhere. Seven of the thirteen species described by Meigen are natives of Britain.

GENUS LOXOCERA, Meig. Antennæ projecting obliquely, longer than the head, the third or terminal joint very long, linear, compressed, with a villose dorsal seta at the base: hypostoma reclined, flat, naked, descending: eyes distant, rounded: forehead somewhat projecting, naked: abdomen elongate, six-ringed, naked: wings incumbent, parallel; the first longitudinal nerve simple.

L. *ichneumonea.* Hypostoma rufous, the sides with a silvery play of colour; forehead testaceous, with a shining black triangular spot: antennæ half the length of the head, black, the first two joints red: thorax testaceous, the upper part of the neck shining black, the prominences on the shoulders, and two lines on the back, of the same colour; scutellum testaceous; abdomen black and shining; legs and halteres yellow; wings somewhat brownish. Three to four lines. Lat. *Musca ichneumonea*, Linn.; *Musca aristata*, Panz. Found in the southern parts of England, along with two other species, *L. elongata* and *L. sylvatica.*

GENUS CHYLIZA, Fallen. Antennæ deflexed, the third or terminal joint elongate, compressed, obtuse, with a villose dorsal seta at the base: hypostoma perpendicular, flat, without a mystax: eyes distant, oblong, the forehead pubescent: abdomen elongate, pubescent, six-ringed: wings incumbent, parallel, the first longitudinal nerve simple.

C. *atriseta.* Head thick, nearly quadrangular, shining black, with a whitish lustre at the margin of the eyes: antennæ sulphur-yellow, the first joint black, the seta longer than the antennæ, of a deep black, and having a short plume: body shining black; abdomen of the males slightly contracted at the base: legs bright yellow; the apex of the hinder thighs brownish: halteres light yellow: wings greyish, the margin from the middle to the apex brown. Three and a half lines. This insect occurs in Britain, as well as *C. leptogaster.*

GENUS LISSA, Meig. Antennæ projecting obliquely, small, the third or terminal joint ovate, compressed, with a villose dorsal seta at the base: hypostoma reclined, somewhat carinated, naked: eyes distant, oblong; the forehead tuberculated anteriorly: abdomen elongate, slender, six-ringed: anterior legs remote: wings incumbent, parallel, the first longitudinal nerve double.

L. *loxocerina.* Hypostoma black, with a silvery-white play of colour: forehead shining black: antennæ with the two first joints small and black, the third reddish yellow; hinder part of the head black, the margin of the eyes white: thorax black, clothed with fine white pubescence: abdomen elongate, cylindrical, black, with a white streak on each side at the incisures; that of the male club-shaped behind, in the female pointed: legs reddish yellow; the anterior pair remote from the hinder; anterior coxæ reddish yellow, thickly clothed with silver-white hairs; hinder coxæ black; the hinder legs longer than the others, and having the tibiæ brown in the middle: halteres yellow: wing-scales wanting. Four lines. Meig. *Zw.* vol. v. pl. lii. fig. 1–4. *Ocyptera dolium*, Fab. Inhabits Britain and some parts of the continent. The generic name is objectionable, as it was previously used by Dr Leach to designate a tribe of crustaceous animals.

Diptera Proboscidæ.

Genus Tetanura, Fallen. Antennæ projecting obliquely, the third or terminal joint elliptical, compressed, and obtuse, having a villose seta in the middle of the back: hypostoma perpendicular, carinated, nearly naked: eyes distant, rounded; the forehead flat and setose: abdomen elongate, cylindric, five-ringed: wings incumbent, parallel; the first longitudinal nerve simple.

T. *pallidiventris.* Hypostoma yellow; forehead shining dark brown, yellow in front, and having a spot of yellow on the crown; antennæ yellow: thorax black, bristly, the sides of the breast reddish yellow: scutellum black: abdomen pubescent, black, the first segment and hinder extremity of the terminal one pale yellow: legs rather long, ferruginous; the anterior pair rather remote from the hinder: halteres white, uncovered: wing-scales not visible: wings large, somewhat brownish. Two lines. Found by Professor Fallen at Esperod in Sweden, during the months of July and August. It is the only species of the genus, and has not hitherto been noticed in Britain.

Genus Tanypeza, Fallen. Antennæ somewhat incumbent, approximating, the third joint oblong, compressed, having a naked dorsal seta at the base; hypostoma somewhat reclined, flat, and naked: eyes oblong, remote; the forehead narrow and naked: abdomen elongate, six-ringed: wings incumbent, parallel; the fourth longitudinal nerve recurved.

T. *longimana.* Hypostoma blackish, with a white play of colour; forehead deep black, margined anteriorly with white, and having a white spot on the crown; palpi and antennæ deep black; the proboscis yellow: body shining black: thorax with an oblique slightly interrupted pubescent band, of a changeable white, on the sides: scutellum black and bristly: abdomen in the male with a small projecting piece behind, which bears a two-jointed seta near the apex, and a small protuberance anteriorly; in the female this appendage is short, pointed, and articulated: legs elongate, bright yellow; the first tarsal joint likewise yellow, and as long as the four following, which are brown: halteres white and naked: wing-scales white, so minute as to be scarcely perceptible: wings hyaline. Three lines. Examples of this species are preserved in the collections of Baumhauer and Fallen. We are unacquainted with its native country.

Genus Calobata, Meig. Antennæ incumbent, small, the third joint elliptical, compressed, the base with a dorsal seta, which is shortly plumose or naked: hypostoma flat, naked: eyes rounded; forehead nearly naked: abdomen elongate, cylindric, five-ringed: legs very long and slender; the tarsi short: wings incumbent, parallel.

C. *petronella.* Hypostoma whitish; palpi and antennæ yellow, the last black at the base, and furnished with a scarcely pubescent seta; forehead reddish yellow, margined with white, and having a black spot on the crown: thorax ash grey, with a yellowish callosity on each shoulder: scutellum grey: abdomen black, with whitish incisures; belly dark grey, wrinkled; style of the females rufous anteriorly, the second joint shining rust-brown, carinated: halteres white: wings hyaline: legs ferruginous, the hinder thighs brown at the apex. Three lines. *Musca petronella*, Linn. Found in England, likewise in the neighbourhood of Edinburgh, and other parts of the southern district of Scotland.

Genus Micropeza, Meig. Antennæ projecting, small, the third joint patelliform and compressed, having a long pubescent dorsal seta at the base: head elongate, elliptical; the hypostoma reclined and naked: eyes rounded, somewhat prominent, remote: abdomen elongate, cylindric, six-ringed: legs filiform, very long, the tarsi short; anterior legs remote: wings incumbent, parallel, the length of the abdomen.

M. *corrigiolata.* Hypostoma white; antennæ deep black, with a white seta; forehead black, deepening in the middle: body black: the sides of the thorax without a yellow vitta: abdomen with white incisures: halteres white: wings hyaline: legs yellow, with black tarsi; all the thighs having a black ring before the apex, and the apex itself black; tibiæ behind passing into black. Two lines. The female larger. Meig. *Zw.* v. 384, pl. liii. fig. 6. *Calobata filiformis*, Lat. Rather frequent. We once found it in very great abundance in the month of June, on flowers, by the sides of the Esk, near Dalkeith.

Genus Ulidia, Meig. Antennæ incumbent, small, distant, the third or terminal joint elliptical, compressed, with a naked dorsal seta at the base: hypostoma descending, impressed, naked, the proboscis somewhat prominent: eyes rounded, distant; the forehead broad, rugose, naked: abdomen ovate, depressed, five-ringed; wings incumbent, parallel.

U. *demandata.* Hypostoma fulvous, wrinkled, whitish above; antennæ dark yellow, the third joint with a brown spot anteriorly: forehead shining dark green, somewhat metallic, wrinkled: thorax more or less brassy; abdomen shining black: legs black; the tarsi rufous, with the apex black: wing-scales very small, and, together with the halteres, white: wings clear, with slender nerves. Two lines. *Musca demandata*, Fab. Meig. *Zw.* v. pl. liii. fig. 12. Has been taken near Paris, and in England.

Genus Timia, Meig. Antennæ distant, small, inserted in a foveola, the third joint oval, compressed, with a naked dorsal seta at the base: hypostoma descending, impressed in the middle, naked, the proboscis and palpi somewhat projecting: eyes oblong, distant; forehead villose: abdomen ovate, six-ringed: wings incumbent, parallel.

T. *apicalis.* Head black; forehead wide, and covered with fine pubescence: body shining black, somewhat setaceous, with a small prominence on each shoulder: abdomen finely pubescent: halteres and wing-scales small and white; wings clear, with the base yellowish, and a triangular brown spot at the apex. Three lines. Meig. *Zw.* v. pl. liii. fig. 16. Examples of this insect are preserved in Wiedemann's collection, and others have been obtained from Portugal.

Genus Platysoma, Meg. Antennæ deflexed, short, the terminal joint oblong, prismatic, obtuse, with a naked dorsal seta at the base: hypostoma somewhat descending, impressed, naked, the proboscis and palpi rather projecting; eyes rounded, remote, the forehead nearly naked; abdomen ovate, four-ringed: wings divaricating.

P. *seminationis.* Variegated with ash-grey and black: hypostoma and palpi black; antennæ dark brown: body grey, with black wartz-like points; abdomen pale beneath, the fourth segment as long as the others taken together: legs entirely black: halteres dark brown: wings marbled with fuscous. Two lines. *Musca seminationis*, Fab. Found in the southern parts of Britain, and on the continent.

Genus Piophila, Fallen. Antennæ incumbent, the third joint elliptical, compressed, with a naked dorsal seta at the base: hypostoma subreclined and provided with a mystax: eyes rounded, remote: the forehead broad, glabrous, convex, and setose: abdomen ovate, somewhat setose, glabrous, five-ringed: wings incumbent, parallel, longer than the abdomen.

P. *casei.* Shining black, glabrous: hypostoma and anterior part of the forehead rufous; antennæ rufous, the third joint, with the anterior edge and the apex, more or less black: hinder part of the head black: anterior legs black; base of the thighs and tibiæ rufous, the middle pair of legs entirely rufous; hinder legs rufous, the thighs before the apex with a black ring, more or less wide: anterior coxæ rufous: halteres white: wings hyaline. One and a half line. *Musca casei*, Linn. Var.; *Tyrophaga casei*, Curtis, *B. E.* vol. iii. fol. 126. Meig. *Zw.* v. pl. liv. fig. 4. The maggot lives in cheese, and leaps.

Genus Homalura, Meig. Antennæ deflexed, distant, the third joint patelliform, compressed, with a naked dorsal seta at the base: hypostoma descending, perpendicular, naked: eyes rounded and remote; the forehead broad, flat, and naked: abdomen ovate, depressed, naked, five-ringed: wings incumbent, parallel, the length of the abdomen.

H. *tarsata.* Body shining black, everywhere thickly covered with tubercular dots: thorax without a distinct cross suture: legs black, with yellow tarsi: stalk of the halteres black, the head globose and white. One and a half line. Meig. *Zw.* v. pl. liv. figs. 8 and 9. Inhabits Austria and England.

Genus Thyreophora, Lat. Antennæ very minute, inserted in a foveola, the terminal joint lenticular, and having a naked dorsal seta at the base: hypostoma descending, reclined, and having a mystax: eyes small and round; the forehead broad, rather prominent, convex, and villose: abdomen oblong, six-ringed: wings incumbent, parallel, longer than the abdomen.

T. *cynophila.* Head bright orange yellow; forehead pubescent, with two black spots: body dark steel blue, shining, everywhere beset with long black hairs: scutellum of the male nearly half the length of the abdomen, truncated at the apex, and bearing a strong seta at each side; that of the female small and triangular: legs dark steel blue, pubescent, the four anterior tarsal joints rufous at the base: wing-scales blackish: halteres white: wings hyaline, with two black dots on each. Four lines. Meig. *Zw.* v. pl. liv. figs. 10, 15. Has occurred in France.

Genus Actora, Meig. Antennæ small, distant, the third joint sub-globose, with a naked dorsal seta at the base: hypostoma perpendicular, descending, pubescent, without a mystax: eyes rounded, distant; the forehead broad, flat, villose: abdomen elongate, six-ringed: wings longer than the abdomen.

A. *æstuum.* Hypostoma white; forehead ferruginous and pubescent; antennæ dark brown: thorax light brown, finely pubescent, with small black dots; sides light grey, with a brownish spot before the base of the wings: scutellum semicircular, light brown: abdomen cinereous: legs dark grey, with rufescent tarsi; in the males the anterior tibiæ and tarsi are thickly covered beneath with shining whitish-yellow hair: wing-scales small and white: halteres white: wings hyaline. Four lines. Meig. *Zw.* v. pl. liv. figs. 19, 20. This insect has been taken in England by Dr Leach.

Genus Lipara, Meig. Antennæ distant, small, the terminal joint lenticular, with a naked dorsal seta: hypostoma descending, pubescent, the forehead broad, rather prominent, and pubescent: eyes rounded, small: abdomen elliptical, pubescent, five-ringed.

L. *lucens.* Head nearly round, finely pubescent; antennæ brown: thorax finely pubescent, brownish grey; when seen in certain directions four dark-brown lines are perceptible, the two central ones abbreviated: abdomen oval, pubescent, the colour of the thorax: halteres brown: wing-scales wanting: thighs dark brown: tibiæ and tarsi yellow: wings yellowish brown. Three lines. Inhabits Germany.

Genus Lucina, Meig. Antennæ distant, the third joint ovate, compressed, with a naked dorsal seta at the base: hypostoma descending, naked, and impressed; the forehead broad, somewhat prominent, slightly pubescent, the vertex setose: eyes rounded, small; abdomen flat, oblong, six-ringed: wings longer than the abdomen.

L. *fasciata.* Hypostoma pearly grey, with a silky gloss; forehead ferruginous; antennæ brown: thorax grey, with brownish longitudinal lines, and black spots and bristles; scutellum grey with a black spot: abdomen grey, with a black band on each segment from the second to the fifth, which is widened anteriorly in the middle, and on the second segment there is a longitudinal streak of white: legs reddish grey, the thighs spotted with black: wings somewhat greyish, with two black spots. Three and a half lines. Germany; Marseilles.

Genus Eurina, Meig. Antennæ distant, short, the third joint ovate, compressed, with a naked dorsal seta: head trigonate, pubescent, hypostoma reclined; forehead broad, flat, rather prominent: eyes small and rounded: abdomen oblong, six-ringed; wings incumbent, longer than the abdomen.

E. *lurida.* Forehead ferruginous; hypostoma whitish; antennæ ferruginous at the base, the third joint entirely brown on the outside, the inside yellow with a brown apex: thorax and scutellum dark brown with deep punctures; abdomen and also the legs ferruginous: halteres white: wings somewhat clouded with brown. Two lines. Examples of this insect are preserved in Baumhauer's collection. Its native country is unknown.

Genus Orygma, Meig. Antennæ small, distant, deflexed, the terminal joint ovate, compressed, with a naked dorsal seta at the base: hypostoma reclined, naked: the forehead broad, flat, and setose: eyes rounded, small: abdomen elliptical, villose, six-ringed: legs strong.

O. *luctuosa.* Forehead black and bristly; hypostoma shining ferruginous, the antennæ of a similar colour: thorax flat and bristly: abdomen elliptical, covered with strong hairs; legs ferruginous and pubescent: halteres uncovered, the wings somewhat brownish. Three lines. Meig. *Zw.* vi. pl. lv. fig. 17. Taken by Dr Leach in the neighbourhood of London.

Genus Camarota, Meig. Antennæ porrect, small, the third joint oblong, obtuse, with a thick villose dorsal seta at the base: hypostoma reclined, naked: forehead wide, flat, somewhat arched anteriorly, pubescent: eyes transversely elliptical: wings incumbent, arched.

C. *flavitarsis.* Hypostoma white; forehead ferruginous and finely pubescent; antennæ black: thorax metallic black, covered with small depressions, and marked with two longitudinal furrows behind: abdomen black: legs of a similar colour, the apex of the tibiæ and the tarsi yellow: halteres dark brown, uncovered: wings brownish grey. Found in Germany, at Paris, and near Marseilles.

Genus Cœlopa, Meig. Antennæ small, the terminal joint small and rounded, with a naked dorsal seta at the base: hypostoma excised, villose, the mouth rather prominent; forehead flat, wide, setose: eyes somewhat rounded: abdomen oblong, setose, five-ringed: wings incumbent, longer than the abdomen.

C. *frigida.* Hypostoma thickly covered with hair, the forehead black and thickly covered with bristles; antennæ ferruginous: thorax bristly, and of a black colour: abdomen black, that of the male thickly pubescent and truncated, that of the female pointed and bristly: halteres white, uncovered; wings somewhat greyish: legs reddish brown, thickly covered with hair. Two lines. *Musca frigida*, Fab. This insect is found in Lapland and the most northern countries of Europe.

Genus Sciomyza, Meig. Antennæ somewhat distant, small, obliquely deflexed, the third joint oblong, obtuse, with a dorsal seta at the base, which is either plumose, or pilose, or naked: hypostoma descending or reclined, the forehead broad, setose, or villose: eyes rounded: abdomen oblong, flat, shortly setose, five-ringed: wings incumbent, longer than the abdomen.

S. *simplex.* Shining ferruginous, except the thorax and the last four joints of the tarsi, which are dark brown: the abdomen is marked with a brown longitudinal line: halteres white, the wings somewhat brownish. Three lines. This genus contains twenty-nine species, none of which have been yet detected in Britain.

Genus Dacus, Meig. Antennæ deflexed obliquely, as long as the hypostoma, the third or terminal joint narrow, elongate, obtuse, compressed, with a naked dorsal seta at the base: hypostoma perpendicular, naked, the forehead broad, somewhat setose: abdomen naked, four-ringed.

D. *Oleæ*. Antennæ ferruginous: thorax cinereous on the back, with three longitudinal lines of black, the sides ferruginous anteriorly, black behind; the shoulders, a small spot at the base of the wings, and another of an elliptical form beneath them, sulphur-yellow; the scutellum of the same colour: abdomen rufous, with three interrupted black bands: legs rufous: halteres white: wings hyaline, having a dark-brown spot at the apex. Two lines. Inhabits Germany, France, and Italy.

Genus Platycephala, Meig. Antennæ projecting obliquely, rather remote, the two terminal joints equal, the third with a naked dorsal seta at the base: hypostoma reclined, naked, the forehead flat, broad, naked: eyes rounded: wings incumbent, longer than the abdomen, the transverse nerves approximating on the disc.

P. *umbraculata*. Forehead ferruginous, with a black impression in the middle; hypostoma likewise ferruginous; antennæ with the first and second joints black, the third ferruginous, the apex black and the seta white: thorax ferruginous, marked with three broad vittæ of a dark-brown colour on the upper side: abdomen wholly dark brown, ferruginous on the under side: legs ferruginous: wings greyish. Two lines. *Musca umbraculata*, Fab. Only three species have been described as pertaining to this genus. The one described above, and *P. planifrons*, have been found in Britain. *P. nigra* occurs in Germany and France.

Genus Sepedon, Lat. Antennæ porrect, longer than the head, the second joint elongate, compressed, setose; third acute, emarginate above, and having a naked dorsal seta at the base: hypostoma perpendicular, descending, naked, the forehead broad and somewhat prominent: eyes rounded and rather prominent: abdomen elongate, five-ringed, naked: hinder thighs thick and spinose beneath: wings incumbent.

S. *sphegeus*. Shining bluish black; antennæ dark brown, the seta black above, white beneath; eyes green, with a dark purple fascia: thorax cinereous, with two dark lines along the back; the sides shining metallic black: halteres white: wings brownish yellow, unspotted; legs bright ferruginous. Three lines. *Sepedon palustris*, Lat. Found during the summer in various parts of the continent, and in England, but is nowhere common.

Genus Dorycera, Hoff. Antennæ remote, the length of the head, the second and third joints equal in length, second linear, compressed, and setose; third conical, ventricose at the base, and furnished with a naked seta on the back: hypostoma reclined, arched, and naked; forehead flat, somewhat prominent, villose, and flat: eyes rounded and a little prominent: abdomen oblong, five-ringed, the style of the female jointed: wings incumbent, longer than the abdomen.

D. *graminum*. Hypostoma shining ferruginous, spotted with black; forehead ferruginous, with two black lines and a white ring round the eyes: antennæ ferruginous, black at the apex: thorax grey, with six black lines; scutellum grey, spotted with black on the sides: abdomen blackish, inclining to reddish brown in the female, and having a pale interrupted line on the back: legs ferruginous, with brown tarsi: halteres bright yellow: wings greyish. Four lines. *Musca graminum*, Fab.; *Tetanocera graminum*, Lat. Inhabits France; apparently not found in Britain.

Genus Tetanocera, Dum. Antennæ porrect, remote, the second joint compressed and setose, third excised on the upper side, compressed, with a plumose or naked dorsal seta: hypostoma descending (rarely reclined) furrowed, naked; the forehead broad and setose: eyes rounded and somewhat prominent: abdomen oblong, five-ringed, somewhat setose: wings incumbent, projecting beyond the abdomen.

T. *Hieracii*. Hypostoma and palpi white; forehead ferruginous, without impressions, with brown spots on the crown, and four black points at the margin of the eyes: antennæ rufous: thorax bright yellow, finely shagreened, and covered with black spots: scutellum yellow, with a black spot: abdomen bluish grey, with three confluent deep-black spots on each segment: legs bright yellow, the apex of the hinder thighs spotted with black: halteres white; wings white, variegated with dark brown. Two lines. *Tephritis Hieracii*, Fab.; Meig. *Zw.* vi. pl. lvii. fig. 18. Not unfrequent in summer among grass. It is found in Britain, along with eleven other species.

Genus Heteromyza, Meig. Antennæ porrect, somewhat remote, the third joint orbicular, compressed, with a naked dorsal seta: hypostoma descending, perpendicular, furnished with a mystax: forehead broad and setose: eyes rounded: abdomen oblong, five-ringed: wings longer than the abdomen, the rib without bristles.

H. *atricornis*. Hypostoma white, with a longitudinal furrow on each side: forehead rufous, having a white ring round the eyes; the crown and hinder part of the head bluish grey; palpi rufous: antennæ deep black, furnished with a long seta: thorax and scutellum bluish grey: abdomen and legs rufous. Three lines. Meig. *Zw.* vi. pl. lvii. fig. 21. Meigen describes four species of Heteromyzæ, of which the only one hitherto detected in England is *H. buccata*, Fallen. No locality is cited for *H. atricornis*.

Genus Helomyza, Meig. Antennæ somewhat deflexed, remote, the third joint oblong or orbicular, having a plumose or naked dorsal seta at the base: hypostoma perpendicular, descending, furnished with a mystax; forehead wide and setose: eyes rounded: abdomen oblong, six-ringed: wings incumbent; the costa setose.

H. *rufa*. The male is ferruginous, with black bristles; the third joint of the antennæ is elliptical, and bears a long plumose seta: abdomen with black bands, which are widened in the middle: hinder knees and two last joints of the tarsi black: wings somewhat brownish, with two white marginal spots at the apex. This species has been found in England by Dr Leach. *H. ustulata*, figured by Curtis (*B. E.* fol. 66), and by Meig. (*Zw.* pl. lvii. fig. 30), is also a native of Britain.

Genus Dichæta, Meig. Antennæ distant, somewhat deflexed, short, the third or terminal joint oblong, compressed, having a pectinated dorsal seta at the base: hypostoma somewhat descending, convex, setose; the forehead wide, setose: eyes rounded: abdomen ovate, five-ringed, that of the male with long setæ at the apex: wings incumbent; the transverse nerves remote.

D. *caudata*. Hypostoma brownish yellow; forehead dark grey; two lower joints of the antennæ brown, the third bright yellow: body dark grey, somewhat bristly; thorax with three broad lines of black: legs dark grey, the tarsi yellow: halteres white: wings greyish. Two lines. A rare insect on the continent. According to Curtis, it has occurred in Britain.

Genus Notiphila, Meig. Antennæ somewhat remote, deflexed, short, the third joint oblong or orbicular, compressed, with a pectinated dorsal seta at the base; hypostoma somewhat descending, rather naked, convex; the forehead broad, setose: eyes rounded: abdomen rather flat, ovate or oblong, five-ringed: wings incumbent, longer than the abdomen; the transverse nerves remote.

N. *cinerea*. Hypostoma fulvous, without lustre, furnished with short bristles on each side of the eyes, which are surrounded with a whitish ring: forehead, thorax, and scutellum ferruginous; on the thorax there are six rows of small tubercles of a black colour: antennæ brown, the third joint yellow at the base: abdomen cinereous, with three black spots on both sides: legs ferruginous, with black thighs: halteres white: wings nearly hyaline. One line and a half. During spring and summer very common in some countries on the *Equisetum palustre*. It occurs in Britain, but does not seem common.

GENUS DISCOMYZA, Meig. Antennæ deflexed, short, third joint oblong, compressed, obtuse, with a pectinated dorsal seta at the base: hypostoma short and rugose; forehead broad, short, and naked: eyes oblong: abdomen depressed, suborbicular, naked, four-ringed: wings deflexed, the length of the abdomen.

D. *incurva*. Black and glossy, the tarsi yellow: halteres small and white: wings somewhat greyish, the anterior margin brown. One line and a half. Meig. *Zw.* vi. pl. lviii. fig. 16, 17. Inhabits Austria and other parts of the continent.

GENUS OCHTHERA, Lat. Antennæ incumbent, short, the third joint elliptical, compressed, with a pectinated dorsal seta at the base: hypostoma descending, naked, convex, coarctate at the apex; forehead broad, impressed, naked: eyes rounded and somewhat prominent: abdomen flat, elliptical, naked, five-ringed: anterior thighs swollen, and spinose beneath: wings incumbent, the fourth longitudinal nerve recurved at the apex.

O. *Mantis*. Hypostoma brownish, with a white play of colour; forehead black: body naked, black, with a metallic lustre, the thorax marked with three black lines; abdomen with a small white spot on each side of the second, third, and fourth incisures: legs black: halteres white: wings somewhat cinereous. Two lines. *Musca manicata*, Fab. Found in August and September.

GENUS STEGANA, Meig. Antennæ incumbent, the third joint oblong, obtuse, compressed, with an irregularly plumose dorsal seta at the base: hypostoma somewhat impressed, and furnished with a mystax; forehead broad and setose: eyes oblong: abdomen oblong, six-ringed: wings longer than the abdomen, incurved, deflexed.

S. *nigra*. Hypostoma and forehead ferruginous, the latter bristly; antennæ yellow: body shining black, somewhat bristly; legs yellow, the hinder thighs brownish: halteres yellow: wings smoke colour. One line and a fourth. Meig. *Zw.* vi. pl. lviii. figs. 24, 25. *Drosophila curvipennis*, Fallen. A scarce insect on the continent, and not occurring at all in Britain.

GENUS DROSOPHILA, Meig. Antennæ incumbent, the third joint oblong, obtuse, compressed, with an irregularly plumose dorsal seta at the base: hypostoma with a mystax, the forehead broad and setose; eyes rounded: abdomen oblong, six-ringed: wings incumbent, longer than the abdomen.

D. *funebris*. Hypostoma and forehead rust-brown: antennæ dark brown, the base yellow: thorax shining testaceous: abdomen shining black, each of the incisures behind with a rather broad yellow band: legs ferruginous: wings rather obscured with brown, but not spotted. One line and a half. *Musca funebris*, Gmel.; *Musca cellaris*, Linn. Found during spring and summer occasionally.

GENUS ASTEIA, Meig. Antennæ deflexed, the terminal joint patelliform, with an irregularly pectinated dorsal seta at the base: hypostoma naked; the forehead broad, and somewhat setose: eyes rounded (fasciated): abdomen naked, five-ringed: wings incumbent, large; the ordinary transverse nerve wanting.

A. *concinna*. Straw colour, the hypostoma with two black spots, and two black longitudinal streaks on the crown: thorax shining black, pale round the outer side, the sides and breast straw-colour: scutellum straw-colour, with a black spot at the base; abdomen and legs entirely straw-colour; wings large and hyaline. One line. Both this and the only other species of the genus, *A. amœna*, occur in England.

GENUS OCHTHIPHILA, Meig. Antennæ deflexed, the terminal joint oblong, compressed, obtuse, with a naked dorsal seta at the base: hypostoma nearly naked; the forehead broad and setose: eyes rounded: abdomen oblong, five-ringed: wings incumbent.

O. *Juncorum*. Light cinereous: antennæ yellow, with the apex black; the abdomen with two rows of black spots: thighs grey; the apex, tibiæ, and first joint of the tarsi bright yellow, the four other joints brown: wings hyaline. One line. Meig. *Zw.* vi. pl. lix. fig. 11. Common in Germany. None of the species, which are seven in number, have been detected in Britain.

GENUS DIASTATA, Meig. Antennæ incumbent, the terminal joint compressed and obtuse; have a dorsal seta at the base, which is densely plumose or naked: hypostoma with a mystax: the forehead broad and setose: eyes somewhat rounded: abdomen oblong, five-ringed: wings incumbent, longer than the abdomen, the transverse nerves remote.

D. *obscurella*. Hypostoma whitish; antennæ and forehead rufous, the margin of the eyes and the crown light grey; the third joint of the antennæ brown at the apex: thorax cinereous: abdomen black, with some lustre: legs rufous: halteres white. One line. Meig. *Zw.* pl. lix. fig. 15. Rather scarce: not indigenous to this country.

GENUS OPOMYZA, Meig. Antennæ deflexed, the terminal joint ovate and compressed, having a dorsal seta at the base, which is shortly plumose or pubescent: hypostoma naked, or furnished with an imperfect mystax; the forehead broad and setose: eyes rounded: abdomen elongate, six-ringed: wings incumbent.

O. *combinata*. Palpi and proboscis white; head, antennæ, thorax, and legs rather bright shining rufous: abdomen of the males linear, shining black, rufous at the base; that of the female more elliptical, flat, rufous, with black bands at the incisures: halteres white: wings small, hyaline, the cross nerves and a spot at the apex dark brown. One line and a third. *Tephritis combinata*, Fab. Inhabits Britain and Germany.

GENUS EPHYDRA, Fallen. Antennæ deflexed, the terminal joint oblong, compressed, and obtuse, with a naked dorsal seta at the base: hypostoma arched or convex, villose; the forehead broad and setose: eyes rounded, somewhat prominent: abdomen elliptical, depressed: wings incumbent, longer than the abdomen.

E. *palustris*. Hypostoma brownish black, setaceous, at least about the mouth; forehead dark green, shining: antennæ black, with a rather thick seta: body shining dark green: scutellum arched: halteres white: wings pale brown: legs black. One line. Found in marshy places.

GENUS HETERONEURA, Meig. Antennæ porrect, the second joint the same length as the third, the latter orbiculate, with a pubescent seta inserted in the middle of the back; forehead flat, furnished with a mystax; the forehead broad and setose: eyes rounded: abdomen elongate, five-ringed; wings incumbent, the transverse nerves approximating in the middle of the disc.

H. *nubila.* Hypostoma and forehead ferruginous, with a whitish lustre round the margin of the eyes; antennæ ferruginous, the third joint somewhat brownish: thorax shining ferruginous, passing into brown, with four dark-brown lines on the back, and a white one on the sides, reaching to the base of the wings; the sides ferruginous: abdomen black: legs rufescent: halteres white: wings somewhat greyish. Male one and a half, female nearly two lines. Inhabits Austria and other European countries.

Genus Gitona, Meig. Antennæ incumbent, the terminal joint elliptical, compressed, having a naked dorsal seta at the base: hypostoma carinated in the middle, and provided with a mystax; the forehead broad and setose: eyes rounded: abdomen ovate, flat, five-ringed: wings incumbent, longer than the abdomen; the transverse nerves approximating.

G. *distigma.* Hypostoma, palpi, and antennæ rufous; forehead of a similar colour, with two brown lines; thorax setaceous, light grey, with three dark somewhat undulating lines: scutellum light grey or yellowish: abdomen shining rufous, with four bands and a dorsal line of black: legs and halteres rufous; wings hyaline. Two lines. Meig. *Zw.* vi. pl. lx. fig. 19. Found in the south of France, and elsewhere.

Genus Milichia, Meig. Antennæ porrect, the terminal joint patelliform, with a naked dorsal seta at the base; hypostoma impressed, and provided with a mystax; the forehead broad and setose; eyes rounded: abdomen ovate, four-ringed: wings incumbent, longer than the abdomen.

M. *speciosa.* Male. Hypostoma white, setaceous about the mouth and sides; palpi black and pubescent; forehead slate-grey with a white play of colour, and when seen in some directions two brownish lines are perceptible: antennæ black: thorax greyish white: scutellum black: abdomen shining silver-white; the belly, halteres, and legs, black: wings hyaline, the anterior edge brown from the middle to the apex. Two lines. Meig. *Zw.* pl. lx. fig. 23. Has been taken near Marseilles, and in Provence.

Genus Leucopis, Meig. Antennæ porrect, the third joint patelliform, with a naked dorsal seta at the base: hypostoma somewhat impressed, naked; the forehead broad and naked: eyes rounded: abdomen ovate, five-ringed, depressed: wings incumbent, longer than the abdomen.

L. *griseola.* White with a bluish tinge; antennæ deep black: thorax with four pale-brown lines, the central one narrowest: abdomen with a black play of colour at the base, and marked with two black dots: halteres white: wings hyaline, with brown nerves: thighs grey, the apex yellow; the tibiæ and tarsi rufous, the former encircled with a pale-brown ring. One line. *Anthomyza griseola*, Fallen; Meig. *Zw.* vi. pl. lx. fig. 28. Found on the continent, but the special localities are not mentioned.

Genus Gymnopa, Meig. Antennæ incumbent, the third or terminal joint somewhat oblong, compressed, and obtuse, with a naked dorsal seta at the base: hypostoma descending, naked, tuberculated; the forehead broad, and nearly naked: eyes rounded: abdomen ovate, glabrous, five-ringed: wings incumbent, longer than the abdomen; the fifth longitudinal nerve abbreviated behind.

G. *subsultans.* Dark metallic green, shining: head and legs black: halteres white. One line and a half. *Syrphus subsultans*, Fab. Found in August and September. The genus contains four species, none of which have been hitherto noticed in Britain.

Genus Chlorops, Meig. Antennæ deflexed, porrect, the terminal joint patelliform, with a naked or pubescent dorsal seta at the base: hypostoma descending, naked; forehead broad and pubescent: eyes rounded: abdomen elliptical, naked, five-ringed: legs simple: wings incumbent, the transverse nerves approximating on the disc.

C. *gracilis.* Straw-colour, as well as the antennæ and legs: forehead rufous: thorax marked with three dark-grey lines, of which the central one is abbreviated behind, and the others in front; and on each side of the breast there is a black spot; there is also a black spot on each side of the first incisure of the abdomen. Three lines. *Meig. Zw.* vi. pl. lxi. fig. 17. Has been taken near Paris on the flowers of *Chrysanthemum leucanthemum*, in Russia, and in Austria. The genus is composed of sixty species, all of them minute insects; and a considerable number appear to inhabit Britain.

Genus Meromyza, Meig. Antennæ deflexed, porrect, the third or terminal joint nearly patelliform, with a naked dorsal seta at the base; hypostoma descending, naked; the forehead broad, rather prominent and pubescent; eyes rounded and somewhat prominent: abdomen conical, naked, five-ringed: hinder thighs thickened: wings incumbent, the transverse nerves approximating in the middle of the disc.

M. *pratorum.* Pale-greenish yellow, as well as the antennæ and legs; hinder part of the head unspotted: thorax with three greenish-grey lines, the central one running along the scutellum also; abdomen, with an interrupted dorsal line of black, and a black spot on each side at the base. Two lines. Meig. *Zw.* vi. pl. lxi. fig. 25. Inhabits Germany and Britain.

Genus Agromyza, Fallen. Antennæ deflexed and porrect, the third joint orbicular, with a naked dorsal seta at the base: hypostoma with a mystax; the forehead broad and setose: eyes rounded: abdomen five-ringed: wings incumbent, longer than the abdomen, the transverse nerves approximating.

A. *denticornis.* Head yellow, with a black point on the crown; antennæ black, with a yellow base; the third joint having a small horn before the apex: thorax with a yellow streak on the sides: scutellum yellow: halteres white: legs black, with yellow thighs. One line. Meig. *Zw.* vi. pl. lxi. figs. 33, 34. *Chlorops denticornis*, Panzer; *Chlorops Meigenii*, Fallen. Found in England and on the continent. The genus is extensive, comprehending sixty-nine species. Few of these have been detected in this country, although there can be little doubt that a large proportion inhabit Britain.

Genus Phytomyza, Fallen. Antennæ porrect, the terminal joint patelliform, with a naked dorsal seta: hypostoma with a mystax; forehead broad and setose: eyes rounded: abdomen elongate, six-ringed: wings incumbent, longer than the abdomen, the transverse nerves placed at the base of the wings, the ordinary one generally wanting.

P. *flavicornis.* Blackish; thorax and scutellum dark grey; antennæ entirely yellow: halteres white: wings somewhat grey: the incisures of the abdomen and the legs yellow. Two thirds of a line. Meig. *Zw.* vi. pl. lxii. fig. 6. Found on the continent, but is not common.

Genus Therina, Meig. Antennæ porrect, the third joint patelliform, with a long naked dorsal seta at the base: hypostoma impressed, and furnished with a mystax; the forehead broad and pilose: eyes rounded: abdomen oblong, five-ringed: wings incumbent, the transverse nerves remote.

T. *femoralis.* Hypostoma ferruginous, forehead of the same colour anteriorly, grey behind; antennæ black: thorax dark grey, with four rather indistinct dark lines: abdomen black: halteres white: wings hyaline: legs ferruginous; the anterior thighs thickened. Scarcely one line. Found on the continent.

Genus Borborus, Meig. Antennæ porrect, the terminal joint sphæroidal, with a naked dorsal seta: hypostoma impressed, and furnished with a mystax; forehead broad, setose, declined: eyes rounded: abdomen flat, five-ringed: hinder metatarsi abbreviated and thickened: wings incumbent, longer than the abdomen (or wanting).

B. *clunipes.* Hypostoma and anterior part of the forehead testaceous: body dark brown: scutellum elongate, flat, setaceous: halteres brown: wings hyaline: the two first joints of the hinder tarsi thickened, the second somewhat longer than the first. One half line. Found in dung; but is rare. It occurs in England.

FAMILY XXIV.—TRINEURÆ.

Genus Phora, Lat. (Plate CCXXXVIII. fig. 30.) Antennæ inserted at the opening of the mouth, globose, with an elongate erect naked seta; palpi exserted, clavate, setose: abdomen six-ringed: hinder legs elongate: wings incumbent.

P. *incrassata.* Black, the forehead tuberculated: palpi and antennæ black: the first incisure of the abdomen margined with white: legs black, the anterior pair with the apex of the thighs, the tibiæ, and tarsi, ferruginous: halteres brown: wings nearly hyaline, somewhat brownish. One and a half line. In September; not rare.

Genus Conicera, Meig. Antennæ erect, conical, with a naked terminal seta: palpi exserted, setose: abdomen six-ringed: wings incumbent.

C. *atra.* Velvet black; forehead pitch-brown; anterior tibiæ and tarsi rufous; wings clear hyaline. Half a line. Found in September; but nowhere common. Apparently not indigenous to Britain.

DIVISION II.—EPROBOSCIDEÆ.[1]

FAMILY CORIACEÆ.

Genus Hippobosca, Linn. (Plate CCXXXVIII. figs. 31 and 31 *a.*) Antennæ gemmiform, inserted into the sides of the hypostoma, and having a naked apical seta: ocelli wanting: the tarsi with equal bidentate claws: wings parallel, incumbent, obtuse, with many nerves.

H. *equina.* Forehead and hypostoma shining ferruginous: eyes pitch-brown: thorax shining dark brown, the shoulders ferruginous; before the scutellum there are three yellow spots, of which the central one forms an acute triangle: scutellum yellow, with black spots on the sides: abdomen pubescent, brownish grey: legs ferruginous, the thighs and tibiæ of the middle pair with a dark ring, the hinder pair with two: halteres black: wings brownish, the marginal nerves dark brown. Four lines. Linn. Fab. On horses and cattle.

We are still indebted to Réaumur for the greater part of our knowledge regarding the very singular mode of production in the genus Hippobosca, or forest-flies, as these insects are sometimes called. That delightful observer has named them *Mouches Araignées.* The larva is hatched and nourished within the body of the mother, and remains there till after its transformation to the nympha state. Hence the term *pupiparous*, as applied to the Hippoboscæ and other genera of the tribe. The nymph, or rather cocoon, is at first of a milky whiteness, with a large plate (plaque) at one end, black and shining, like ebony. It is of a round and flattened form, emarginate at the plated end, where it forms two rounded or horn-like eminences. It becomes entirely black soon after exclusion, and the skin or covering, of a cartilaginous or scaly texture, resists a strong pressure of the fingers, and is even difficult to cut with the sharpest scissors. The body of the mother scarcely equals the dimensions of the nymph, and it has often been a subject of marvel how the greater should proceed from the less. It appears, however, that the cocoon is possessed of an expansive power, which is probably exercised the moment after its exclusion from the body of the parent. The hardness and solidity of the skin, though well qualified to defend the nymph from injury, might seem to present a serious obstacle to the escape of the perfect insect. But nature, so complete and bountiful in all her doings, and so pervaded even in her minutest operations by the perfect wisdom of her great Author, has provided against this seeming inconvenience by a beautiful contrivance. When we examine the larger end by means of a microscope, we shall perceive the feeble trace of what in fact constitutes a kind of cap or cowl, and which may sometimes be made to spring off even by the touch of a penknife. When the perfect insect is ready for exclusion, it finds it an easy matter to manage this piece of natural mechanism. The coriaceous envelope to which we have alluded is, in fact, the distended and somewhat altered skin of the larva, and within it Réaumur succeeded in detecting the exuviæ of the nymph. The phenomena of transformation are, therefore, so far analogous to what we observe in the coarctate pupæ of some other dipterous tribes, and the chief anomaly consists in the larva passing the entire period of its existence within the body of the mother, and being *born* in the pupa state.[1]

---

[1] In our copy of Meigen's *European Diptera*, the work by which we have been guided in the systematic portion of our exposition of the order, there is (at page xxxiii. of the first volume) a brief exposition of the characters of Division I. Proboscideæ. This we have given at page 258 of the present treatise. In the sixth and last volume of the German author we do not, however, find any indication of Division II. Presuming, nevertheless, from the strong disparity of character presented by the Coriaceæ, when compared with the preceding families, that they must constitute the other principal branch of the dipterous order, we have applied the name of Eproboscideæ, as significative of the division sought for. It was so applied by Latreille (*Gen. Crust. et Insect.* t. iv. p. 360), as well as (excepting *Nycteribia*) by Dr Leach (*Wernerian Memoirs*, vol. ii. p. 547), to the family in question. The species of which it is composed are in truth of a very singular structure and economy, and altogether of a nature so anomalous, as to cause some doubts as to their proper position in the system. They are now regarded as constituting a separate order, under the name of Homoloptera, by Leach, Macleay, Stephens, and other English naturalists, and form the family Pupipara of Latreille. Some contrariety of opinion still exists regarding the structure of the mouth. We shall here satisfy ourselves by a quotation from the last-named entomologist, to whom we have been already so deeply indebted. "La tête de ces insectes, vue en dessus, est divisée en deux aires ou parties distinctes, dont l'une postérieure et principale, ou composant plus spécialement la tête, porte les yeux, et reçoit, dans une échancrure antérieure, l'autre partie. Celle-ci se partage aussi en deux, dont la postérieure plus grande et coriace porte latéralement les antennes, et dont l'autre constitue l'appareil manducateur. La cavité inférieure et buccale de la tête est occupée par une membrane; on voit sortir de son extrémité un suçoir, naissant d'un petit bulbe ou pédicule avancé, composé de deux filets ou soies très rapprochés, et recouvert par deux lames coriaces, étroites, alongées et velues, qui lui font l'office de gaîne. Que ces lames ou valvules représentent, ainsi que je l'ai présumé, les palpes des autres diptères, ou qu'elles soient les pièces d'une gaîne proprement dite, comme le pense M. Dufour, à l'occasion d'une espèce d'ornithomyie (*Annales des Scienc. Nat.* x. 243, xi. 1), où il a decouvert deux petits corps, qu'il prend pour des palpes, il n'en serait pas moins vrai, que la trompe de ces insectes differerait sensiblement de celle des diptères précédents, et que la gaîne, dans ce cas, aurait plus de rapports avec celle de la trompe de la puce, dont elle s'éloignerait cependant par l'absence d'articulations. (*Règne Animal*, t. v. p. 538.)

Genus Ornithobia, Meig. Antennæ small, immersed, inserted on the sides of the hypostoma, papillary, naked: ocelli wanting: tarsi with unequal bidentate claws: wings parallel, incumbent, with three nerves.

O. pallida. The colour of the head is ferruginous; the proboscis of a similar colour, shorter than the head: thorax flat, rounded, shining black, with a rather large ferruginous spot on each shoulder, and two lines of the same colour in the middle; the hinder part setaceous, at least on the sides; scutellum transverse, ferruginous, the hinder margin bristly: halteres white: abdomen ferruginous, oval, pubescent: wings nearly hyaline, with pale nerves: legs ferruginous, pubescent, robust: the first four joints of the tarsi very short, the fifth longer, with two long unequal claws, the outer claw shorter than the interior one. Two lines. Rare; apparently not found in Britain.

Genus Ornithomyia, Lat. Antennæ gemmiform, setose, inserted into the sides of the hypostoma; vertex with three ocelli; tarsi with tridentate claws: wings incumbent, obtuse.

O. avicularia. Greenish yellow: antennæ and proboscis ferruginous; eyes pitch-brown: thorax blackish on the sides, with a yellowish longitudinal line: wings smoke colour with dark-brown nerves, the longitudinal nerves not very distinct: legs pubescent. Two to two and a half lines. *Hippobosca avicularia*, Linn. Degeer, vi. 114, pl. xvii. fig. 21–27. These insects occur on different species of birds, but never on quadrupeds,—a fact in their history which, in connection with the difference of structure, renders their generic separation from Hippobosca the more advisable. Latreille thinks that their metamorphoses resemble those of the last-named genus. The species above described is extremely vivacious, runs swiftly, sometimes side foremost like a crab, and flies with considerable facility.

Genus Stenopteryx, Meig. Antennæ gemmiform, setose, inserted into the sides of the hypostoma: vertex with three ocelli: tarsi with tridentate claws: wings very narrow, acute, longer than the abdomen.

S. hirundinis. This species is very closely connected with those of the preceding genus, differing chiefly in the long, narrow, pointed wings: the colour is ferruginous, with pitch-brown eyes: the antennæ are covered with long black setæ. Two lines. *Hippobosca hirundinis*, Linn.; *Stenepteryx hirundinis*, Leach; *Ornithomyia hirundinis*, Lat. Meig. *Zw.* vi. lxiv. fig. 5. Found on different kinds of swallows, especially the *Hirundo Apus* of Linn. The wings of this species are not well adapted for flight. Réaumur once found as many as thirty in a swallow's nest.

Genus Anapera. Antennæ gemmiform, setose, inserted into the sides of the hypostoma: ocelli wanting: tarsi with tridentate claws: wings short and acuminated.

A. pallida. Ferruginous; the abdomen brown: antennæ with numerous long black hairs: thorax rhomboidal, the anterior part embracing the head on both sides; sinuated on each side, but widened in the middle, and the back impressed with a deep longitudinal line: the hinder part setaceous, especially towards the sides: scutellum transverse: legs robust, especially the thighs, and covered with long hair: wings short, scarcely longer than the abdomen, somewhat greyish, with ferruginous nerves, the apex acute. Two and a half lines. *Ocypterum pallidum*, Leach; *Mouche-araignée*, Geoff. *Ins.* ii. 547, 2. Found on swallows, especially the swift.

Genus Melophagus, Lat. Antennæ papillary, immersed, inserted in the sides of the hypostoma: eyes linear and small: ocelli wanting: tarsi with bidentate claws: wings wanting.

M. ovinus. Ferruginous; the abdomen brown; forehead wide, with the crown smooth and without ocelli, the other parts setaceous: proboscis as long as the head, and porrected: thorax embracing the head anteriorly: abdomen oval: legs robust, pubescent; the tarsi short, with bidentate claws. Two lines. *Hippobosca ovina*, Linn. Found in considerable numbers among the wool of sheep. Another species occurs upon the stag.

Allied to the preceding genus is that named Braula by Dr Nitzsch. The only known species lives upon the honey-bee, and is figured by Germar.[2] It is absolutely blind.[3]

Genus Nycteribia.

We shall conclude this lengthened exposition of the dipterous order by a few observations on the genus Nycteribia of Lat., *Phthiridium* of Hermann, concerning the true position of which very various opinions have been entertained. The species are in fact entirely apterous, having neither wings nor halteres. They bear a general resemblance to spiders. The head is extremely small, and as it were implanted on the anterior and dorsal portion of the thorax, in the form of a little capsular tubercle. The eyes seem composed of minute grains. The thorax is semicircular. Even Latreille (in his earliest work) was so far misled by the anomalous aspect of these insects as to mistake the very Class to which they belonged. He consequently placed them among the Arachnides. In this he was followed by Dr Leach,[4] who was probably not aware that the great French entomologist had long before rectified his error. When a species of the genus was first observed on a bat by Colonel Montagu, he thought it an entirely new insect, and named it, on account of its rapid movements, *Celeripes Vespertilionis.*[5] It appears, from an expression in the *Fauna Suecica*, that Linnæus described it as a *Pediculus*. The generic name of *Phthiridium*, bestowed by Hermann the younger,[6] being posterior in date to that of Latreille, ought not to be adopted. We may add, that the antennæ, which the German author did not observe, and which he stated did not exist, have been detected by Latreille.[7] They are extremely short, advanced, bi-articulate, and inserted close to each other, on the emargination of the upper edge of the head. The eyes are placed immediately beneath them.

These curious insects, as far as yet known, occur on bats, over which they move with great rapidity; but when withdrawn from their natural nidus they become quite confused, and almost incapable of locomotion. Their heads being placed as it were upon their dorsal aspect, it was difficult to understand how they satisfied their appetite; and we owe to Colonel Montagu the observation, that when they suck the blood of bats they place themselves in a reverse position on their backs. Of the few species known, two are found in Britain, on the greater and the lesser horse-shoe bats. Another species occurs in the Isle of France.[8]

ORDER IX.—SUCTORIA, DEGEER.[1]

In this order the mouth consists of a sucker of three parts (two maxillæ and a ligula), contained between two articulated blades (the labium), forming by their union a trunk or beak, cylindrical or conical, and covered at the base by a pair of scales, supposed to represent the palpi. The species undergo a genuine metamorphosis analogous to that of several Diptera, such as the *Tipulariæ* of Latreille.

The genus PULEX of Linnæus composes the entire order. The body is oval, compressed, covered by a tough integument, and divided into twelve segments, of which the anterior three constitute a short thorax, and the remainder the abdomen. The head is small, much compressed, rounded above, truncated and ciliated in front, and furnished on each side with a little circular eye, behind which, and lodged in a groove, we find certain small moveable articulated bodies, which are the true antennæ. Towards the anterior part of the head, and near the origin of the sucker, are placed another pair of appendages, which Latreille and others have regarded as the antennæ, but which are now with greater propriety considered as maxillæ, or parts of the mouth. Between these is placed the sucker, composed of a bivalvular articulated sheath, and three setæ. The sheath, according to Dugès, corresponds to the labial palpi, while two of the setæ represent the mandibles, and the remaining one is regarded as the analogue of the ligula.

In regard to the species,—"Chacun," says Latreille, "connait la Puce commune." In this country we call it *flea;* and, presuming that it is nearly as well known here as in France, we shall not trouble our readers with a detailed description. The female lays about a dozen eggs, of a white colour, and slightly viscous. From these ere long proceed little lively worms, which move like serpents, or roll themselves about spirally, or in circles. They are at first white, but become ere long of a reddish hue, and are composed of a scaly head, without eyes, furnished with two minute antennæ, and of numerous segments bearing little tufts of hair, and two hooks at the caudal extremity. The mouth exhibits some small moveable pieces, of which the larva makes use in pushing itself forward. They remain about twelve days in that condition, and then each larva encloses itself in a little silk cocoon, where it becomes a nymph, and from which, after about an equal lapse of time, the perfect insect issues forth. The common flea (called by naturalists *Pulex irritans,* see the figure last referred to) occurs in almost all countries. It is parasitical on the bodies of several other animals besides the human kind (of which it prefers children and the gentler sex, owing to the superior softness of their skin), such as dogs, cats, hares, among quadrupeds,—and pigeons, poultry, and swallows, among birds. Defrance, who has published some interesting observations on the eggs and larvæ, has also shown that bathing domestic animals has no effect in ridding them even of the perfect insect, which he has seen resume its wonted functions after a continuous immersion of twenty-two hours. The process, however, is useful, in as far as it appears to annoy the pregnant females, which do not endure immersion above eleven hours. In Dalecarlia the natives place hare-skins in their beds, and other parts of their houses, for the fleas to nestle in. They then destroy them by dipping the skins in hot water, or holding them over a fire.

The genus Pulex is by no means numerous in species. A large yellow kind occurs upon the mole, and a banded species (*P. fasciatus* of Bosc) is found upon the fox. Professor Graham thinks he caught it in Clova. The *Pulex penetrans* of Linn., known to the French colonists of America by the name of *Chique* (Plate CCXXXIX. fig. 14), is by some regarded as belonging to a distinct genus. Its sucker is as long as its body (fig. 14, *b*). It introduces itself beneath the toe nails, or under the skin of the feet, where the female speedily acquires a considerable bulk in consequence of the growth of her eggs (fig. 14, *a*). The numerous young to which these give birth sometimes occasion malignant ulcers, difficult to cure, and occasionally mortal. They are extirpated by using a lavement of tobacco juice, or other acrid infusion. The negroes, from frequent practice, extract them with great skill.[2]

ORDER X.—THYSANOURA, LAT.

The insects of this order, like those of the preceding, are apterous, or without wings. In addition to the usual number of legs, they are provided, either along their sides, or at the extremity of the abdomen, with peculiar organs, which assist the purposes of locomotion. They are masticators, that is, furnished with mandibles and maxillæ. They do not undergo metamorphoses. All the species are of small size, of rather soft consistence, and are generally covered either with shining silvery scales or hairs. They avoid strong light, and seldom quit their retreats till the shades of night have fallen. Some inhabit the interior of houses, keeping themselves concealed in presses, in the interstices of shutters, window-sashes, and other wooden fabrications;—others occur under stones and in humid places. The order is divisible into two families.

FAMILY I.—LEPISMENÆ, LAT.

This family corresponds to the genus *Lepisma* of Linnæus. The antennæ are setaceous, usually very long, and divided from their base into many small articulations. The palpi are distinct and projecting. The abdomen is furnished inferiorly on each side with a range of moveable appendages in the form of false legs, and is terminated by articulated setæ, of which three are more obvious than the others. The body is of an elongated form, and covered with small shining silvery scales. The mouth is composed of a labrum, two almost membranaceous mandibles, a pair of maxillæ, each furnished with a palpus of from five to six articulations, and of a labium of four emarginations, bearing two quadri-articulate palpi. The thorax consists of three perceptible portions. The abdomen, which becomes gradually narrower towards its posterior extremity, is provided, in addition to the false legs just mentioned, with an anal appendage or scaly style, compressed, and composed of two pieces, after which we may observe the three articulated setæ prolonged beyond the body. The legs are rather short—the haunch often very large, much compressed, and squamiform. Several species occur in window-sashes which are seldom opened, beneath the planks of presses where there is any damp or moisture.

[1] APTERA (pars) Linn.; SIPHONAPTERA, Lat.; APHANIPTERA, Kirby.

[2] See *Recherches sur les Caractères Zoologiques du genre Pulex*, par M. Ant. Dugès, in the *Annales des Sciences Nat.* Octobre, 1832; Curtis's *British Entomology*, pl. ccccxvii.; and Mr Westwood *On the Structure of the Antennæ in the Order Aphaniptera*, *Ent. Mag.* vol. i. p. 359.

A few seek the protection of stones. They run swiftly, and some leap well by means of their caudal appendages. The Linnæan genus is now divided into two.

In the genus Machilis, Lat. (*Petrobius*, Leach), Plate CCXXXIX, fig. 8, the eyes are extremely composite, almost contiguous, and occupy the larger portion of the head. The body is convex and arched above, and the abdomen is terminated by small setæ, adapted for leaping, and of which the central one, placed above the others, is much the longest. The maxillary palpi are very large, and pediform. The thorax is narrowed, with its first segment smaller than the others, and arched. These insects leap well and frequently. They dwell in stony and covered places. The species are few in number, and, as far as yet known, are European. We found the *P. maritimus* of Leach[1] in Fingal's Cave, in the island of Staffa.

In the genus Lepisma properly so called (*Forbicina*, Geoffroy, Leach), Plate CCXXXIX. fig. 7, the eyes are very small, distant, and less composite than in the preceding genus. The body is flattened, and the three terminal setæ are inserted on the same line, and are not adapted for leaping. The haunches are very large. The greater number are found in the interior of houses. They run swiftly, and when seized their silvery scales come off upon the fingers. The softness of the masticating organs in this genus would induce us to believe that they are incapable of gnawing hard materials. The most common species, *L. saccharina*, is said by Linnæus and Fabricius to feed on sugar and decayed wood,—and, according to the former, it likewise gnaws books and woollen garments. Geoffroy, however, is of opinion that it preys on the little *Psocus pulsatorius*, a small neuropterous insect, usually without wings, which we find both in houses and beneath the bark of trees. This Lepisma measures about four lines in length. It is of a silvery white, with a tinge of lead colour, and without spots. It is said to have come originally from America. Another species, which is represented by the figure last referred to, is distinguished by its ash-coloured body, spotted with black, and marked down the back by four black lines. Its localities are similar to those of the preceding species.

FAMILY II.—PODURELLÆ, Lat.

In this family, which corresponds to the genus *Podura* of Linn., the antennæ consist of only four articulations. The mouth does not exhibit distinct and projecting palpi. The terminal seta is forked, and when not in action is kept bent beneath the abdomen. These insects are extremely small, the body soft, elongated, with an oval head and two eyes, each formed of eight small granules. The legs exhibit only four distinct joints. The tail is soft, flexible, and composed of an inferior piece, moveable at the base, with two articulated appendages at the extremity, susceptible of being approximated, separated, or crossed. By striking this caudal process against the plane of their position, these insects possess the power of leaping into the air like fleas, although with less activity. They generally fall upon their backs, with their tails stretched out behind. Some are found on plants, beneath the bark of trees, or under stones; others on the surface of stagnant waters. They even occasionally occur, during time of thaw, in great quantities, on snow. When collected in numbers, they resemble a sprinkling of gunpowder.

These insects are oviparous, and undergo no transformations. They are completely formed on leaving the egg, although they speedily increase in size, and frequently change their skins. Degeer informs us that he observed them in Holland, alive and active, during the prevalence of a strong frost. The aquatic species do not long survive a removal from the water. They speedily shrivel up and die. But the terrestrial species support uninjured the heat of the mid-day sun even in dry and dusty regions. As far as we know, all the ascertained species are European, though we doubt not the genera exist in other quarters of the globe.

Parasita.

In Podura properly so called (Plate CCXXXIX. figs. 12 and 12 *a*), the antennæ are of nearly equal thickness throughout, and without annuli or small articulations at their extremity. The body is almost linear or cylindrical, with the thorax distinctly articulated, and the abdomen narrow and oblong.

In the genus Smynthurus, Lat. (*Podura*, Linn.), the antennæ become attenuated towards the extremity, and are terminated by an annulated portion, composed of small articulations. The thorax and abdomen seem united into a single globular or ovate mass. This genus corresponds to the second section of the *Poduræ* of Degeer. When touched, these insects make great leaps into the air by means of a setiform process at the end of the abdomen, resembling that of the preceding genus;—but they are moreover furnished with a very extraordinary organ, which we do not find in Podura proper. Beneath their body, and just between the points of the two forks of the tail, there exists an elevated cylindrical portion, from which issue two long membranous threads, transparent, extremely flexible, and glutinous or humid. They are rounded at the extremity, almost as long as the insect's body, and are thrown out with force and celerity, one on either side, from the cylindrical portion just mentioned, according to the insect's pleasure.

In regard to the uses of these peculiar parts of structure, Degeer observed that some Smynthuri which he had placed in an earthen vessel ejected their slimy organs whenever they found themselves, against their will, slipping down the sides of their prison. They then hung, as it were, suspended by these filaments, until they had time to take up a fresh position.[2] It may thus be reasonably inferred that their natural use or function is to prevent the insect's falling, when, after the execution of a powerful leap, it happens to alight upon a perpendicular or inclined surface. Degeer's observations apply to *Sm. fuscus*, Lat.,[3] a comparatively large species, synonymous with *Podura atra* of Linn.

Order XI.—PARASITA, Lat.[4]

The insects of this, our concluding order, are apterous, like those of the preceding; but their bodies are unprovided with articulated appendages, or other organs of locomotion, except the legs. Their organs of sight seem to consist solely of smooth or simple eyes (*yeux lisses*). Their mouth is in great part internal, and exhibits externally either a muzzle or projecting protuberance, enclosing a retractile sucker, or two membranaceous approximate lips, with a pair of hooked mandibles. These insects form in the Linnæan system the genus Pediculus, containing an extensive and varied group, known under the general and repulsive name of *lice*, and exhibiting in their structure and economy a great deal to interest the philosophical naturalist, notwithstanding the associations by which we unavoidably connect their existence with that of wretchedness and vice.

[4] Aptera (pars) Linn.; Anoplura, Leach.

The unrestricted genus may be said to be generally characterized by a flattened body, almost transparent, and divided into eleven or twelve distinct segments, of which the anterior three bear the six legs. The first of these segments often assumes the form of a thorax. The stigmatic openings are very distinct. The antennæ are short, of uniform thickness, composed of five articulations, and frequently inserted in an emargination. On each side of the head there are one or two small simple eyes. The legs are rather short, and are terminated by a very strong claw, or by a couple of hooks directed one towards the other. These parasites, as many know by experience, attach themselves to man, beast, and feathered fowls. They likewise fix their eggs to hair and feathers; and as their generations are neither few nor far between, their superabundant increase under certain circumstances, not yet clearly understood, is sometimes such as to produce disease and death. The malady is called *phthiriasis*, from φθείρ, the Greek for louse.[1] Fabricius placed the Pediculi in his order *Antliata* (or Diptera), guided no doubt by a consideration of the parts of the mouth; while Dr Nitzsch, who has studied these insects with great attention, now ranks them with the Hemiptera, and at the same time classes the cognate genus Ricinus in the orthopterous order.

In the genus PEDICULUS properly so called (Plate CCXXXIX. fig. 11 and 11 *a*), the mouth is very small, mammillæform, and tubular, placed at the anterior extremity of the head, and, while not in action, enclosing a sucker. The tarsi consist of an articulation almost equal in size to the tibia, and terminated by a very strong claw, which, bending inwards upon a small projection, forms as it were a kind of nipper. Such of the species as Latreille has examined presented only a pair of simple eyes, one on each side.

Of the three species which infest the human race, *P. humanus corporis* is without spots. It infests the inner garments of beggars, and others who attach no importance to personal cleanliness, and is the cause of the disease above alluded to. The second species, *P. humanus capitis*, is more of an ash colour, with brown or blackish spots around the stigmatic openings, and the lobes of the abdomen are more salient. It occurs on the heads of children, and of dirty adults. In both these species the head and thorax are obviously distinct from the abdomen. In the third species, which forms the genus *Phthirus* of Dr Leach, the body is broad and rounded, the thorax very short and almost confounded with the abdomen, and the four posterior legs are very strong.

Of all these insects the powers of multiplication are great. Swammerdam viewed them as hermaphrodites, in as far as he could not satisfy himself regarding their distinctive sexual characters. But Leeuwenhoeck and Degeer, and recently Latreille and Doctors Nitzsch and Alibert, have shown that they do not differ essentially in these respects from other allied tribes. They are all oviparous, and their eggs are deposited on hair (see Plate CCXXXIX. fig. 11 *b*) or garments. The young are hatched in five or six days, and after several castings of their skin, or in about eighteen days, they become fit to reproduce their kind. In this way it has been calculated that a brace of females may prove the parents of *eighteen thousand young* in the space of two months. Oviedo remarked that the pediculi left the Spanish sailors at a certain latitude during their voyage to the Indies, and made their appearance again on the homeward progress about the same latitude. This we think was somewhere near the tropics; but the observation does not seem to have been confirmed by any special observations in more modern times. It is said, however, that in India they occur only on the head. These insects, however disgusting to people of refinement, are greedily sought after and *eaten* by those who may by some be regarded as belonging to the inferior orders, viz. Negroes, Hottentots, and Monkeys.

In the genus RICINUS of Lat. (Plate CCXXXIX. fig. 10), which corresponds to *Nirmus* of Hermann and Leach, the mouth is placed beneath, and consists exteriorly of two lips, and a pair of hooked maxillæ.[2] These insects, with the exception of a species found on dogs, are all bird-lice, that is, parasitical on the feathered creation. Their head, which, in common with the antennæ, occasionally differs in the sexes, is usually very large,—in some of a triangular form, in others semicircular or lunate,—and is frequently furnished with angular projections. Latreille has perceived a pair of simple eyes on each side of the head in several species. Besides the parts of the mouth just mentioned, Savigny satisfied himself of the presence of maxillæ, each bearing a very small palpus, and concealed by the labium or lower lip, which is also palpigerous. There is likewise a kind of tongue. The Ricini are much less sluggish in their movements than the Pediculi properly so called. They glide about among the feathers of birds with considerable agility, and are captured with difficulty, by reason of the flatness of their forms and adhesive propensities. When a bird dies, however, they assemble together about the base of the beak, and other parts of the head, and moving about with an air of inquietude, they seem to watch for an opportunity of making their escape to some living prey. M. Leclerc de Laval detected portions of the plumage in their stomachs, and he is of opinion that these constitute their sole subsistence; but Degeer found the Ricinus of the chaffinch gorged with blood; and their extreme anxiety to change their quarters the moment that circulation ceases, argues a fancy for something more than feathers.

We have at last brought to a conclusion an article which the reader may possibly regard as of inordinate length, but which the writer has certainly found far too narrow for the proper elucidation of several departments of his subject. "And here it is not out of place to remark, that it is the very perfection of the divine workmanship which leads every inquirer to imagine a surpassing worth, and grace, and dignity, in his own special department of it. The fact is altogether notorious, that in order to attain a high sense of the importance of any science, and of the worth and beauty of the objects which it embraces, nothing more is necessary than the intent and persevering study of them. Whatever the walk of philosophy may be on which man shall enter, that is the walk which of all others he conceives to be most enriched by all that is fitted to entertain the intellect or arrest the admiration of the enamoured scholar. The astronomer who can unravel the mechanism of the heavens, or the chemist who can trace the atomic processes of matter upon earth, or the metaphysician who can assign the laws of human thought, or the grammarian who can discriminate the niceties of language, or the naturalist who can classify the flowers, and the birds, and the shells, and the minerals, and the insects which so teem and multiply in this world of wonders,—each of these respective inquirers is apt to become the worshipper of his own theme, and to look with a sort of indifference, bordering on contempt, towards what he imagines the far less interesting track of his fellow-labourers. Now each is right in the admiration he renders to the grace and grandeur of that field which himself has explored; but all are wrong in the distaste they feel, or rather in the disregard they cast on the other fields which they have never entered. We should take the testimony of each to the worth of that which he does know, and reject the testimony of each to the comparative worthlessness of that which he does not know; and then the unavoidable inference is, that that must be indeed a replete and a gorgeous universe in which we dwell,—and still more glorious the Eternal Mind, from whose conception it arose, and whose prolific fiat gave birth to it in all its vastness and variety."[1] (T.)

---

[1] It is well described by M. Alibert, in his treatise *Sur les Maladies de la Peau.*

[2] The genus Ricinus was established by Degeer, who first recognised that these insects were distinguished from Pediculi by the existence of mandibles. The name was applied by the ancients to certain acarideous species of the genus now called *Ixodes*, and for that reason has not been adopted by some modern naturalists, who prefer the name of *Nirmus*.

ENTRE DUERO E MINHO, one of the provinces into which the kingdom of Portugal is divided. As its name denotes, it is bounded on the north by the river Minho, which divides it from Spain, and on the south by the river Duero. The Atlantic Ocean is its western boundary, and on the east a chain of elevated mountains separates it from the province of Tras os Montes. It has by far the most dense population of any part either of Spain or Portugal, and extends over a surface of 291 square leagues. The number of its inhabitants in 1798 amounted to 907,965.

It enjoys the best climate, the most fertile soil, and the most beautiful rivulets, not only of Portugal, but of the whole peninsula. Its vegetable productions are oranges, lemons, maize, wheat, and especially wine. The latter article is the great object of export, and forms the principal trade of the kingdom, as almost all the red wine, commonly named port, from the city whence it is shipped, is the growth of Entre Duero e Minho. Both its sea coasts and rivers abound with most excellent fish, which forms the foundation of considerable commerce. Considerable manufactures are conducted, which furnish hats, linens, sail-cloth, woollen cloths, and various kinds of silks and satins. These, though not sufficiently cheap to be sent to other parts of Europe, supply the demands of the kingdom, and a portion is exported to Brazil and the settlements on the coast of Africa. The rivers next in importance to those which bound it are the Lima, the Cabado, the Deste, and the Ave, all which run from east to west, and form natural defences, aided by the mountains, against any invading enemy. The city of Braga is the capital, though Oporto is in every respect the first city in the province, only that Braga, as the see of an archbishop, is usually considered as the chief place. This province lies between 41. 6. and 42. 6. north latitude.

ENTREPAS, in the manège, a broken pace, which is neither walk nor trot, but is somewhat of an amble.

ENTRY, in *Law*, signifies taking possession of lands or tenements, where a person has a right so to do.

ENTRY *of an Heir*, in *Scotch Law*, that legal form by which an heir vests in himself a title to his predecessor's estate.

ENUMERATION, an account of several things, in which mention is made of every particular article.

ENUMERATION, in *Rhetoric*, a part of the peroration, in which the orator, collecting the scattered heads of what had been delivered throughout the discourse, makes a brief and artful relation or recapitulation of the whole.

ENVELOPE, in *Fortification*, a work of earth, sometimes in the form of a simple parapet, and at others like a small rampart with a parapet. It is sometimes raised on the ditch, and sometimes beyond it. Envelopes are of a zigzag form, in order to enclose a weak ground, with single lines, where that is practicable, or to save the expense of horn-works, crown-works, and tenailles, where room is wanting for such defences. Envelopes in a ditch are called sillons, counter-guards, and lunettes.

ENVIRONNE', in *Heraldry*, signifies surrounded with other things. Thus, they say, a lion environné with so many bezants.

ENVOY, a person deputed to negotiate some affair, not of a very solemn or important nature, with any foreign prince or state.

ENVY, pain felt, and malignity conceived, at the sight of excellence or happiness in another.

ENZELLI, a town of Persia, in the province of Ghilan, built entirely of reeds, as the sandy soil will not bear a more solid edifice, and consists of two parts, New and Old, inhabited by Persians, Armenians, and Russians. It is six miles north of Reshd.

EONIANS, in *Ecclesiastical History*, the followers of Eon, a wild fanatic of the province of Bretagne, in the tenth century. He concluded, from the resemblance between *eum*, in the form of exorcising malignant spirits (*per eum, qui venturus est judicare vivos et mortuos*), and his own name Eon, that he was the son of God, and ordained to judge the quick and dead. Eon, however, was solemnly condemned by the council at Rheims in 1148, at which Pope Eugenius III. presided, and he ended his days miserably in a prison. This insane fanatic left behind him a number of followers and adherents, whom persecution and death could not persuade to abandon his cause, or to renounce an absurdity which, as Mosheim observes, one would think could never have gained credit in any place but bedlam.

EOOA, EAOOWE, or MIDDLEBURG. This island is the most eastern of the Friendly Islands, in the South Pacific Ocean. It is about thirty miles in circuit, and has an elevated and unequal surface. The north-east coast rises suddenly, but the north-west consists of valleys, meadows, and plains, abounding with groves of fruit trees, sugar-canes, bananas, shaddocks, and vegetables of various sorts. It was discovered in 1643, by Tasman, who called it Middleburg. Long. 174. 30. E. Lat. 21. 24. S.

EORIA, in *Mythology*, a feast celebrated by the Athenians in honour of Erigonus, who, by way of punishment for their not avenging the death of his father Icarus, induced the gods to inflict on their daughters the curse of loving men who returned not their passion. The feast was instituted by the order of Apollo.

EOSTRE, in *Mythology*, a Saxon goddess to whom sacrifices were offered in the month of April, called the month of *Eostra*; and hence the name *Easter*, which the Saxons retained after their conversion to Christianity, applying it to the festival celebrated in commemoration of our Saviour's resurrection.

EPACTS, in *Chronology*, the excess of the solar month above the lunar synodical month, and of the solar year above the lunar year of twelve synodical months; or of several solar months above as many synodical months, and several solar years above as many dozen synodical months. See CHRONOLOGY.

EPAMINONDAS, son of Polymnis the Theban, born about 410 B.C., was one of those distinguished characters whose appearance forms an epoch in the history of their country. The position of Thebes was not such as to enable it to take a prominent part in the affairs of Greece; and, excepting during the short period when Epaminondas and Pelopides were at the head of the government, it seems to have been dependent either on Sparta or on Athens, according as the power of the one or the other prevailed. The earlier years of Epaminondas were spent under the direction of Lysis the Pythagorean philosopher; and, if we may credit the story told by Diodorus, he was the fellow-student of Philip of Macedonia. Devoted though he seems to have been to the study of philosophy, he did not neglect those lighter accomplishments which add grace to the character; and Nepos even thinks it necessary to tell us the names of the masters from whom he derived his knowledge of music and dancing.

At the period when Epaminondas appeared upon the stage, the small republics of Greece were torn to pieces by intestine dissensions; at one time the party of the rich and noble prevailed, at another the power of the democracy was predominant. Of the latter party Athens was the main prop, whilst Sparta was the powerful friend of the former. It does not appear that Epaminondas in his earlier years took any prominent part in support of either faction, being probably disgusted by the intrigues and remorseless cruelty which he saw practised by all parties in the pursuit of whatever object they had in view. He was present indeed at the battle of Mantinea (385 B. C.), fought between the Arcadians and Spartans; and it was mainly through his efforts that it was decided in favour of the latter, on the very same ground which was destined a few years afterwards (362 B. C.) to witness his own death, and the defeat of his allies.

During the whole period of his political life his friendship with Pelopidas was uninterrupted, and, according to Plutarch, nothing reflected greater glory on both, than that they never allowed a feeling of rivalry to interfere with their exertions for their common country. Yet no two individuals could possibly be more dissimilar in character, as Pelopidas loved all the pomp and splendour of power, whilst Epaminondas was better pleased to remain in poverty and retirement. The nobles, mistrusting their own strength, received a Spartan garrison (382 B. C.) into their citadel, and Pelopidas and the chiefs of the popular party were banished; but Epaminondas, who was supposed to be more engaged in the speculations of philosophy than in the active affairs of life, was allowed to remain. Three years afterwards a conspiracy was formed to recover the independence of Thebes; but though his friend Pelopidas was at its head, Epaminondas refused to join in the attempt, wisely judging that the bloodshed and rapine which would inevitably follow any violent change in the government must more than counterbalance the good anticipated from the success of the popular party. The conspirators succeeded without his assistance, yet prudently adopted the moderate counsels which he recommended. The Spartans made an attempt to recover their power, but, being defeated by Pelopidas, were induced to listen to terms of accommodation. A general diet of all the states of Greece was summoned at Sparta, in order that peace might be established on just and sound principles. Epaminondas was the deputy appointed by Thebes, and the able manner in which he maintained the interests of his country did not disappoint the expectations of his fellow-citizens. He refused to emancipate the cities of Bœotia from the control of Thebes, unless Sparta was prepared to act the same part towards those subject to her in Laconia. Negotiations were broken off, as neither party showed a disposition to yield, and orders were sent to Cleombrotus the Spartan general, then in Phocis, to commence hostilities against the Thebans. It was now that Epaminondas, by the consent of all, was appointed to the chief command, and the measures which he took to protect the country from the incursions of Cleombrotus were so complete that they compelled the Spartan general to retire from Chæronea, where he had taken up his position. Cleombrotus descended from the mountains to the sea shore, and passing along the difficult and rugged coast at the foot of Mount Helicon, reached without interruption the plains of Leuctra, at no great distance from Thebes. Here he found the troops of the Thebans posted on the heights around; and in the council of war which was held it required all the ability of Epaminondas to persuade the officers that the fate of their country ought to be staked on the chances of a general engagement. In this, however, he succeeded, and immediately drew out his men in order of battle.

The result of his arrangements was a complete victory, gained in July 371 B. C. To his friends who congratulated him he answered, "that his chief pleasure arose from his parents being alive to enjoy his triumph." Two years after this battle he entered the Peloponnesus at the head of 70,000 men, carrying terror and desolation to the very gates of Lacedæmon, which had not for five or six centuries seen the smoke of an enemy's camp. He was compelled, however, to retire, by the able generalship of Agesilaus, though not until he had devastated the whole country around. On his return home he was brought to trial, along with Pelopidas and the other generals, for having retained his command four months beyond the time specified by law. He recommended the other generals to plead as their excuse his superior orders, and then boldly said to the assembly, "I acknowledge that the law condemns me to death; all I ask is, that the sentence passed on me may be couched in these words: Epaminondas was punished for having conquered the Spartans at Leuctra, for having besieged Lacedæmon, and rebuilt Messene." The boldness of this answer was of course applauded, and Epaminondas acquitted; yet his enemies had sufficient influence with the people to exclude him from all honourable employment. Some time afterwards he redeemed his character by a successful campaign against Alexander, the tyrant of Pheræ, in Thessaly, and by delivering his friend Pelopidas from the hands of that unprincipled despot. A war broke out between the Tegeates in Arcadia, who had implored the assistance of the Thebans, and the Mantineans, who were supported by Lacedemon. The two armies met near Mantinea, the modern village of *Paleopoli*, when Epaminondas employing a manœuvre similar to that which had succeeded at Leuctra, gained a complete victory, but was wounded by a javelin, the iron point of which remained in his body. Before he expired, he inquired for the generals Deiphantus and Jollidas, and being told they were dead, he added, "Then persuade the Thebans to make peace." In fact, from this moment, Thebes, to use the expression of an ancient writer, was a javelin deprived of its iron point, and ceased to be formidable. Epaminondas died on the 4th July 362 B. C. one of the most perfect models that Greece presents of a great captain, a true patriot, and a philosophic sage.

His life was written by Plutarch, but it has been unfortunately lost; there are, however, many details of it contained in the lives of Agesilaus and Pelopidas, and also in his moral works. But it is to Xenophon that we are indebted for the chief facts. The life of Epaminondas by Cornelius Nepos has been evidently mutilated. The reader may also consult Diodorus Siculus, x. xvi. xv.; Pausanias, Polybius, Ælian, and Valerius Maximus. A long and uninteresting life has been published by De la Tour, Paris 1739, 12mo; by Meismer, in German, 12mo, Prague, 1798; and in the *Mémoires de l'Acad. des Inscript. et Belles Lettres*, vol. xiv. p. 113.

EPARER, in the manège, signifies the flinging of a horse, or his yerking and striking with his hind legs.

EPAULEMENT, in *Fortification*, is a kind of breastwork, constructed to cover the troops in front, and sometimes also in flank. In a siege, an epaulement of eight or ten feet in height is generally raised near the entrance of the approaches, in order to cover the cavalry which is placed there to support the guard of the trenches. These works are commonly constructed of filled gabions, or of fascines and earth intermixed. The term epaulement is frequently applied to any work thrown up to defend the flank of a post or other place; it also denotes sometimes a demi-bastion, and at others a square orillon, for covering the cannon of a casemate.

EPAULETTES are a kind of military shoulder-knots, which are made of different materials, according as they are worn by officers or by common soldiers.

EPENTHESIS, in *Grammar*, the interposition or insertion of a letter or syllable in the middle of a word; as *alituum* for *alitum*, *relligio* for *religio*, *induperator* for *imperator*, and the like.

EPERIES, a city of Hungary, in the circle of the Hither Theiss. It is the seat of the several boards for the government of the circle, and contains 806 houses, and 7426 inhabitants, who make much linen and woollen goods, and some very excellent wine. Long. 21. 10. 25. E. Lat. 48. 58. 45. N.

EPHA, or EPHAH, in Jewish antiquity, a dry measure, equal to three pecks and three pints.

EPHEBÆUM, in *Antiquity*, the place where the ephebi or youth exercised; or, as some think, where those who designed to exercise met and agreed on the kind of exercise which they should contend in, and what should be the victor's reward.

EPHEBI, among the Athenians, a designation given to their young men when they arrived at eighteen years of age, at which period they had their names entered in a public register.

EPHEMERA, from ἡμερα, *a day;* a diary fever, or a fever of one day's continuance.

EPHEMERIDES, in *Astronomy*, tables calculated by astronomers, showing the actual state of the heavens for every day at noon; that is, the places in which all the planets are found at that time. It is from these tables that the eclipses, conjunctions, and aspects of the planets are determined. In England, the *Nautical Almanack, or Astronomical Ephemeris*, published annually by anticipation, under the direction of the Board of Longitude, is the most considerable work of the kind.

EPHESUS, the chief city of Ionia, in Asia Minor, on the south side, and near the mouth of the river Cayster (now called Kutchuc Mendere, or Lesser Mæander), was 320 stadia, or forty miles, to the south of Smyrna, and 540, or three days' journey, from Sardis, the capital of Lydia. It was situated at the extremity of a rich and beautiful plain, called Campus Cilbianus, through which the river flowed, and which still retains its former character, after centuries of Turkish oppression. Ephesus was originally founded by the Leleges and Carians, who were compelled to make way for an Ionian colony led by Androclus, son of Codrus. The inhabitants continued to be distributed over the neighbouring district until the reign of Crœsus (560 to 546 B.C.), when, being attacked by that prince, they are said to have dedicated their city to Diana, by fastening a rope from their walls to the temple of the goddess. They gradually deserted the ancient site, and approached the position of the sacred temple, where they are said to have continued until the time of Alexander the Great (330 B. C.). Lysimachus having obtained possession of the city (302 B. C.), compelled the inhabitants, by inundating the ancient site, to remove higher up to a spot which he surrounded with walls. We find that it was delivered over to the kings of Pergamus by the Romans, after the defeat of Antiochus (190 B. C.); and, amidst all the changes of government which subsequently took place, Ephesus continued to increase in riches and prosperity, being in the time of Strabo (24 B. C.) the emporium of Asia. It was considered by the Romans as the first of the three chief cities of Asia, the two others being Smyrna and Pergamus; and in the later divisions of the country under the Christian emperors, we are told by Hierocles that it was the capital of the important provinces of Asia. Ephesus was lost to the empire at an earlier period than the other parts of Western Asia. Some time before the commencement of the Crusades (1096 A. D.), a chief of the Saracens made himself master of Ephesus; but the crusaders restored it to its ancient master. In the fourteenth century it fell into the hands of a prince of Caramania named Sasan; and from this time it ceased to belong to the Greek empire. It still, however, continued to exist down even to the time of Timur or Tamerlane (1370 A. D.), who for a considerable period had a camp under its walls, and who is supposed to have destroyed it, as he did many other cities.

Ephesus was more particularly celebrated on account of the temple of Diana, which, according to Pausanias, existed even before the arrival of the Ionians. Its architect was Chersiphron of Cnossus, in Crete, assisted by his son Metagenes; and as the ground on which the temple was erected was marshy, it is said that he obtained a firm foundation by means of heaps of charcoal and wool, packed closely together in sacks. It was the only temple in Asia which escaped the doom pronounced against them by Xerxes on his return from Greece (480 B. C.); but it was burnt to the ground 356 B. C. by a madman named Eratostratus, who is said to have taken this method of immortalizing his name. This event took place the very night on which Alexander the Great was born; and the temple seems to have remained in ruins till that monarch offered to restore it, on condition that he should be declared the founder. This proposal, however, the Ephesians declined to accept, cunningly soothing the wounded vanity of the hero by saying, "that it was beneath the dignity of one god to erect a temple to another." Having collected sufficient funds amongst themselves and their neighbours, they entrusted its restoration to the architect Dinocrates, who is reported to have conceived the extravagant project of forming a statue of Alexander out of Mount Athos. The new edifice was much larger, and constructed with more magnificence, than the original temple. It was 425 feet in length and 220 in breadth, with 227 pillars, each 60 feet in height. It is said to have been of the Ionic order of architecture. The interior was adorned with numerous pieces of sculpture by the celebrated Praxiteles. Thraso and Scopas were also employed in its decoration; and there was a picture in it by the celebrated Apelles. The statue of the goddess was more particularly the object of veneration, having been preserved in safety amidst all the vicissitudes to which the temple and city had been exposed. It was of wood, and, according to Pliny, was covered with some unctuous substance, to guard it from decay. The service of the temple was performed by priests called Megabyzæ, who were eunuchs, and to whom were added a number of priestesses. The temple was an asylum for criminals of every description. Alexander extended the privilege to a stadium round the edifice; Mithridates fixed it at a bow-shot; and Antony doubled the distance, so that it included part of the town. It may easily be conceived that such a privilege must have been liable to great abuses; and in fact it became at last so dangerous to the peace of the city, that Augustus caused it to be abolished. It was seven stadia, or about an English mile, from the walls of the city; but no modern traveller seems yet to have discovered its remains. Pococke has indeed given a ground plan of what he considered as the temple; but his description by no means agrees with what is related of the seventh wonder of the world.

The ruins of Ephesus are seen half a mile from the Turkish village of *Aiasluk*, which seems to have risen about the middle of the fourteenth century. Chandler thus speaks of its present appearance: "Ephesus was situated by the mountains which are the southern boundary of the plain, and comprehended within its walls a portion of Mount Prion and of Corissus. Mount Prion is a circular hill; Corissus a single lofty ridge, extending northward from near Mount Pactyas, and approaching Prion, then making an elbow, and running westerly towards the sea. We entered Ephesus from *Aiasluk*, with Mount Prion, and the exterior lateral wall of a stadium which fronted the sea, on our left hand. We measured the area, and found it 687 feet long. The vestiges of the theatre alluded to in the Acts of the Apostles, which was very capacious, are farther on in the side of hetæ || hori

Ephorus.

the same mountain. Going on from the theatre, you come to a narrow valley which divides Mount Prion from Corissus. Within the valley you find broken columns and pieces of marble, with vestiges of an odeum in the slope of Prion. Beyond the odeum the valley opens gradually into the plain of *Aiasluk*. Keeping round by Prion, you meet with vestiges of buildings, and come to the remains of a large edifice. This was the gymnasium. The street at the entrance of the city from *Aiasluk* was nearly of the length of the stadium. The opposite side was composed of edifices equally ample and noble. The way was between a double colonnade, as we conjectured, from the many pedestals and bases of columns scattered there. This street was covered by one leading from the plain to the valley. It had on the left the front of the stadium, and the theatre with the portico adjoining. On the right are ample substructures, with pieces of massive wall. These remains reach as far as the portico, and have behind them a morass, once the city port. The extent of the city towards the plain, on which side it was washed by the Cayster, cannot now be ascertained; but the mountainous region has preserved its boundary, the wall erected by Lysimachus, which is of excellent masonry. Near the entrance of Ephesus from *Aiasluk* are the vaults of several sepulchres, and others along the slope of Corissus show that the Ephesians buried likewise within the city." (*Travels in Asia Minor*, chap. 35.)

EPHETÆ, judges who in early times presided over he five criminal courts of justice at Athens, taking cognizance of every description of homicide. They were ifty-one in number, and required to be of noble birth. Solon first separated the Areopagus from the other four courts; and from this time the jurisdiction of the ephetæ vas confined to cases of unintentional or justifiable homiide. It formed part of their duty to see that the person vho had committed the act should be properly expiated y sacrifice and other rites. He was obliged to leave his ountry, by a particular road, for a certain time, which vas generally eight years, though at Athens it was proably undetermined. During this time he was bound to eep at a distance from places of public resort; and when e returned, a reconciliation took place, either with the indred, or certain chosen ploratores. (See Plutarch, *Solon*, 29; Pollux, viii. 125.)

EPHOD, in Jewish antiquity, a part of the priestly abit, being a kind of girdle, which, being brought from ehind the neck over the two shoulders, and hanging own before, was put across the stomach, then carried ound the waist, and made use of as a cincture to the unic. There were two sorts of ephods; one of plain linen or the priests, and the other embroidered for the high riest.

EPHORI, ancient Doric magistrates, whose power and nfluence seem to have varied at different times. In Sparta the college consisted of five, and they entered on their nnual office at the autumnal solstice, the beginning of e Lacedæmonian year. The first of these magistrates ave name to the year, in the same way as the first elected consul did at Rome; and they began their official dues by publishing a species of edicts, in which they appointed the secret officers or κρυπτοι. In this edict was ound the strange metaphorical expression for subjection nd obedience, "that they must shave the beard and obey e laws." They held their daily meetings in an office et apart for them (ἀρχειον), where they were also in the abit of eating together.

It is supposed by Müller, in his able treatise on the political institutions of the Dorians, that the duties of the phori were originally limited to the superintendence of ales, and of the public markets. Aristotle informs us, whilst describing their judicial powers, that they decided civil causes, but that the council presided over all capital crimes. It appears therefore that the court of ephori gave judgment respecting civil duties and property. The Periæci and Helots, when they were in Sparta, were also under its jurisdiction. But the ephori gradually extended their authority; and it seems to have been the usual course of events in Greece, that the civil courts should enlarge their influence, whilst the power of the criminal courts was continually on the decline.

The circumstance which seems principally to have extended the jurisdiction of the ephori, was the privilege they enjoyed of instituting an inquiry into the official conduct of all magistrates, excepting that of councillors. We do not mean to say that this scrutiny always took place; but the ephori had it in their power to compel any magistrate to stand his trial, if they had remarked any thing suspicious in his administration. The king was not exempted from this power, but bound to yield as implicit obedience as the lowest officer of the state. Thus we find Cleomenes tried for bribery before the Persian war. But it must not be supposed that the ephori could of themselves punish with death: they were only the accusers before a larger court, which consisted of all the councillors, of the ephori themselves, who seem to have acted both as accusers and judges, of the other king, and probably of several other magistrates, who had all equal votes. The ephori had only the power to impose fines, and to demand immediate payment. Thus Agesilaus was fined for endeavouring to make himself popular; whilst Archidamus was reprimanded for having married a wife of too small stature. Sometimes we find them punishing one man for having introduced money into the state, another for indolence, and a third for the most extraordinary reason, namely, that he was generally ill treated and insulted.

The ephori appear from very ancient times to have had a right to transact business with the popular assembly in preference to any other magistrates. They could convene the people and put the vote to them. They had great authority in transacting with foreign nations, admitting ambassadors, and dismissing them from the confines of the kingdom. In time of war they were empowered to send troops on whatever day they thought fit, and seem even to have been able to determine the number of men. The army was then entrusted to the king, or some other general, who received from them instructions how to act, and was even restrained in his proceedings by deputies whom the ephori sent to watch over him. The general could be recalled by the scytala, and their first duty was to visit the office of the ephori. It is impossible, however, to believe that the ephori could act by their own authority on such important occasions as these; they could only have been the agents and plenipotentiaries of the popular assembly. It must in fact have been the decrees of the people which they put in execution.

The office of the ephori was abolished by Cleomenes, but restored under the Roman dominion. (See Müller's *Dorier*, Breslau, 1824, t. ii. p. 111–129.)

EPHORUS, a celebrated Greek historian of Cunæ in Æolis, born about the year 362 B. C., a year memorable for the battle of Mantinea. His father's name was Demophilus, or Antiochus; and being contemporary of Eudoxus and Theopompus, he studied along with them under the philosopher Isocrates. Of his personal history we are entirely ignorant; and if it were not for the high character he enjoyed among the ancients as an orator and historian, his name would be unworthy of notice. It was Isocrates who directed his attention more particularly to that branch of literature in which he eventually became so eminent; and, to mark the distinctive peculiarities in the mind and character of his two pupils Theopompus and Ephorus, the philosopher is reported to have said, " se calcaribus in Ephoro, contra autem in Theopompo frenis uti solere."

The great work of Ephorus was a history of the wars between the Greeks and Persians, in which, like Herodotus, he introduced, in the form of episodes, the description of foreign and barbarous nations, yet only in as far as they were connected with and served to illustrate Grecian history. It must be allowed, however, that the Greeks considered the work of Ephorus as an universal history; but then this may be explained from the extreme vanity of that nation, in believing that their history was the central point on which that of the whole world turned. Meier Marx, who has published a collection of the fragments of this work, has endeavoured to give us the contents of the thirty books of which it was composed.

The first book contained an account of the return of the Heraclidæ into the Peloponnesus, and the change of affairs consequent upon that event; and the second was occupied with the state of the rest of Greece; and the third narrated the departure of the Greek colonies to Asia. In these three books he thus brought the history of Greece and Asia down to that period when they began to assume a peaceful aspect, probably a few years before the commencement of the Median war. After this introduction he proceeded to describe separately each country which subsequently became the scene of important transactions; in the fourth book Europe, in the fifth Asia and Africa, and in the sixth he probably gave an account of the nation of the Pelasgi. The seventh book contained the most ancient traditionary notices of Sicily, and probably all he could collect respecting the original inhabitants of Italy and the adjacent islands. The eighth book narrated the various changes of fortune to which those nations had been subject, who in succession held the supreme command in Asia, namely, the Assyrians, Lydians, and Persians. The fragments which remain refer principally to the affairs of Crœsus. In the ninth book we had the origin, changes, and migrations of the Amazons, Scythians, and other nations who inhabited the coasts of the Pontus and those northern countries, whence, through Thrace and Thessaly, he returned to Greece and its affairs. Then it was that Ephorus reached the period when, like every Greek historian, he imagined that the transactions of the whole world became centred in the causes and events of the Persian war; and then also he began to treat his subject with more copiousness, for we find that in his tenth book he had already brought down his history to the times of Miltiades, about 490 B. C. In his eighteenth book he had reached Dercyllidas, 399 B. C. In his twenty-fifth he had arrived at the battle of Mantinea, 362 B. C. We thus see that he must have employed seven or eight books in describing thirty-seven years, whilst his last four or five books could contain the history of only twenty-two years. The part of the thirtieth book which gave an account of the sacred war was composed, not by Ephorus himself, but by his son Demophilus; at the conclusion of the war Ephorus took up the thread of the history, and continued it to the siege of Perinthus, 340 B. C. According to Diodorus Siculus, the whole period treated of was 750 years.

For a more full description of the life of Ephorus, and a collection of the fragments of his history which have been preserved, the reader may consult *Ephori Fragmenta a Marxio*, Caroluh, 1815; Creuzer, *Symbolik und Mythologie der alten Volker, besonders der Griechen*, Leipsic, 1819; Vossius *De Historicis Græcis*, Lugd. Bat. 1651; and Ulrici, *Charakteristik der antiken historiographie*, Berlin, 1833.

EPHRAIM, in *Ancient Geography*, one of the tribe divisions of Palestine. Ephraim and the half tribe of Manasseh are blended together by the sacred writer; and it appears that Ephraim occupied the more southern, and the half tribe of Manasseh the more northern parts, but both seem to have extended from the Jordan to the sea. Ephraim also denotes a kingdom, on the separation of the ten tribes from the house of David, called the kingdom of Israel and Samaria.

EPHREM SYRUS, an ancient Christian writer, in the fourth century, deacon of Edessa, was born at Nisibe in Syria. He was greatly esteemed by Basil, Gregory Nazianzen, and other eminent men. He wrote against the opinions of Sabellius, Arius, Apollonarius, and the Manichæans, and acquired such reputation that he was styled the doctor and the prophet of the Syrians. He died in the year 378. The best editions of his works are, that of Oxford, in 1708, in folio; and that of Rome, from 1732 to 1738, in Syriac, Greek, and Latin, six vols. folio.

EPHYDOR, in *Antiquity*, an officer in the Athenian courts of justice, whose business it was to provide the plaintiff and defendant with equal water hour-glasses. When the glass had run out, they were not permitted to speak any longer; and therefore we find them very careful not to lose or mis-spend one drop of the water. Whilst the laws quoted by them were reciting, or if any other business happened to intervene, they gave orders that the glass should be stopped.

EPIBATÆ, part of the crew which manned an Athenian vessel. The triremes of this people were of two sorts, either swift-sailing vessels or transport ships. The latter were filled with land forces which it was intended to transport to some particular point, and, being heavily laden, were never employed in battle excepting in cases of great emergency; the former contained only the necessary crew for the working and defence of the vessel. The troops embarked in these transports were, like all other passengers by sea, called Epibatæ. But the crew also of the swift-sailing vessels consisted of two distinct bodies of men; the soldiers intended for their defence, called Epibatæ, who seem to have occupied the place of our marines; and the sailors who were employed for the purpose of working the vessel. These Epibatæ were perfectly distinct from the land forces, the oplitæ and pellestæ, and were entirely devoted to the sea. It seems difficult to decide how many of them were attached to each ship, for there are only two passages in ancient authors from which any inference can be drawn. Herodotus (vi. 15) says, that the Chians, when they armed one hundred ships against the Persians, embarked forty able-bodied citizens as Epibatæ in each trireme; whilst Plutarch (in *Themist.* 14) tells us that there were only eighteen Epibatæ on board the Attic triremes at Salamis, four of whom were archers, and the rest heavy-armed men. See Böckh, *Die Staatshaushaltung der Athener*, vol. i. p. 301, Berlin, 1817.

EPIBATERION, a poetical composition, in use amongst the ancient Greeks. When any person of condition and quality returned home after a long absence or journey into another country, he called together his friends and fellow-citizens, and made them a speech, or rehearsed a prepared copy of verses, in which he returned solemn thanks to the immortal gods for his happy return, and ended with an address by way of compliment to his fellow-citizens. These verses formed what the Greeks call επιϐατεριον, *epibaterium*, from επιϐαινω, *I set out.* On the occasion of departure they had another analogous composition, called *apobaterium*.

EPIC, or HEROIC, *Poem*, a poem expressed in narration, formed upon a story partly real and partly feigned, and representing, in a sublime style, some signal and fortunate action, distinguished by a variety of great events, in order to form the morals, and affect the mind with the love of heroic virtue. See Poetry.

EPICEDION (from επι, *upon*, and κηδος, *funeral*), in Greek and Latin poetry, a poem, or poetical composition, on the death of any one. At the obsequies of persons of consequence there were three kinds of discourses usually made; that rehearsed at the *bustum* or funeral pile was called *nenia;* that engraven on the tomb, *epitaphion;* and that spoken in the ceremony of his funeral, *epicedion.* We have two beautiful epicedions in Virgil; that of Euryalus, and that of Pallas.

EPICEDIUM, in ancient poetry, a poem rehearsed during the funeral ceremonies of persons of distinction.

EPICHARMUS, a celebrated poet of the old comedy, the son of Helothales, a native of Cos, but who having been carried into Sicily at the age of three months, is generally known as a Sicilian, the name of his adopted country having prevailed over that of the country of his birth. He was a pupil of Pythagoras; for there seems abundant proof that Epicharmus the Pythagorean and Epicharmus the father of the old comedy were one and the same person. He was the author of many comedies, written in trochaic tetrameters, which he began to exhibit about the year 500 B. C., and continued down to the reign of Hiero, 477 B. C. Plautus is said to have imitated him (Hor. *Ep.* ii. 1, 57), and Ennius translated one of his moral works. He used to say that the principal requisite in a philosopher was not to believe rashly. (Cic. *De Petit. Cons.* c. 10.)

Epicharmus is much less known and esteemed than his peculiar style of writing and dramatic skill deserve. The subjects of his plays were mostly mythological, being parodies or travesties of mythology, nearly in the style of the satirical drama of Athens. Thus, in the comedy of Busiris, Hercules was represented in a most ludicrous light as a voracious glutton; and he seems again to have been exhibited in the same character in the Marriage of Hebe. It is supposed that the figures on a vase now preserved in the British Museum, and which was found at Bari in the kingdom of Naples, were intended to represent the characters in the play of Epicharmus entitled Vulcan, or the Revellers. (See Millin, *Galerie Mythologique,* xiii. 48, for the figures.) The play began, as we are told, with Vulcan chaining his mother Juno by magical charms to a seat, from which he only released her after long entreaties. Vulcan being, in consequence of this act, ill treated by his parents, entirely deserted Olympus, until Bacchus, having made him drunk, placed him on an ass, and thus brought him in jolly merriment back to Olympus. But Epicharmus, like Aristophanes, sometimes handled political subjects. Thus, according to Hemsterhuis (*ad Pollux,* ix. 4. 26), the piece called Ἁρπαγις, or the Plunderings, which described the devastation of Sicily in his time, had a political meaning; and this was perhaps also the case with "The Islands." The style of his plays was not less various than his subjects; he passed from rude buffoonery to a more serious strain, introducing maxims and moral sentences, together with precepts of the Pythagorean philosophy. That the dramatic style of Epicharmus was perfect in its kind is proved by the great admiration in which it was held by the ancients, particularly by Plato.

EPICHIROTONIA, amongst the Athenians. It was ordained by Solon, that once every year the laws should be carefully revised and examined; and that if any of them were found unsuitable to the actual state of affairs, they should be repealed. This was called επιχειροτονια των νομων, from the manner of giving their suffrages by holding up their hands. (See a further account of this custom in Potter, *Archæol. Græc.* tom. i. p. 242.)

EPICŒNE, in *Grammar,* a term applied to nouns, which, under the same gender and termination, mark indifferently the male and female species. Such in Latin are *aquila, vespertilio,* and the like, which signify equally a male or female eagle or bat.

Grammarians distinguish between *epicœne* and *common.* A noun is said to be common of two kinds, when it may be joined either with a masculine or a feminine article; and epicœne, when it is always joined to some of the two articles, and yet signifies both genders.

EPICTETUS, a native of Hierapolis, in Phrygia, was born of humble parents, in the first century of the Christian era. In his youth he was the slave of Epaphroditus, the freedman of Nero, an individual of gross and vulgar habits. It is said that he was one day amusing himself in twisting the leg of his slave, when Epictetus exclaimed, "you will break it;" and the event justified the prediction. "I told you so," added the philosopher, without changing a muscle of his countenance. Of his personal history it may be readily imagined that we know but little; even his name is unknown to us, for Epictetus merely marks his condition of life, signifying in Greek *a slave* (επικτητος). He must, however, have received his freedom; for, when Domitian published his edict about the year 90, banishing philosophers from Italy, Epictetus retired to Nicopolis in Epirus, where it is supposed he passed the rest of his life. Spartianus indeed asserts that he lived at Rome in great intimacy with the Emperor Hadrian; but if this information be correct, he does not seem to have profited much by his intercourse with the rich, for his house is said to have been without a door, and to have had no furniture except a table, a bed, and a miserable mattress.

Epictetus was a Stoic, but possessed none of the vain boastings nor austerity of that sect of philosophy. The virtue which he prized most dearly was modesty. Being an enemy of Epicurus and his doctrines, he admired Socrates, and has left us a magnificent picture of the true cynic. As we might expect from his principles, Epictetus during the whole of his life made war on opinion. All his doctrines were reduced to this point: Our actions depend on ourselves; all other things are independent of us: let us therefore devote our whole attention to the correction and amendment of the first; but it is madness to make any effort to avoid the other, for they are entirely beyond our control. *Support pain and fly pleasure,* was the grand leading precept of Epictetus. It is indeed beautiful, but difficult to follow. Suidas says he wrote much, but nothing has come down to us. Arrian, the most celebrated of his disciples, collected, with much care and diligence, the discourses and principles of his master, and composed several treatises on them, viz. 1. On the Life and Death of Epictetus; 2. Twelve books of Familiar Discourses of this philosopher (these two works are lost); 3. Eight books of Dissertations on Epictetus and his Philosophy, four of which only remain; 4. Enchiridion, or Manual of Epictetus, which is preserved, and in which he presents a concise view of the moral philosophy of the Phrygian. Arrian dedicated this work to M. Valerius Messalinus, consul in the year of the city 901. There are also in Stobæus many moral sayings of Epictetus, which have been collected by Blancard, Copenhagen, 1629, 12mo. The first Greek edition of the Enchiridion was published at Venice, 1528, 4to. See also Heyne's edition with notes, Dresden, 1776, 8vo.

EPICUREAN Philosophy, the system of doctrine, canonical, physical, and ethical, taught by Epicurus, and maintained by his followers, who, from the name of their master, received that of Epicureans.

The first part of this threefold system regarded the canons or rules of judging. Disgusted with the subtle-

Epicurean Philosophy.

ties and paradoxes of the Stoics, Epicurus endeavoured to introduce a more simple and natural method of judging, and, instead of artificial modes and scholastic distinctions, appealed to the common sense and natural perceptions of mankind as the ultimate basis of all reasoning. These he assumed as first principles, or rather as unerring guides; and by giving excessive latitude to an elementary definition, which, if properly guarded and restricted, might have served as the foundation of a rational system of logic, he was betrayed into errors and extravagances not less startling than those from which it had been his object to escape. Cicero has reproached him with an alleged unphilosophical contempt of logic; but this censure, when duly weighed, must be pronounced to be entirely without foundation. Epicurus, it is true, despised and even ridiculed the modes of reasoning by means of which the Stoics evolved the paradoxes in which they delighted; and he was neither acquainted with nor had any relish for those analytical investigations in which the members of that philosophical sect displayed so much unprofitable ingenuity. But, on the other hand, all the errors with which his system is easily chargeable, may be traced to the logical strictness with which he adhered, in all his reasonings, to the primary canon which he had laid down, and to the implicit faith which he was consequently led to repose in those sensible perceptions and intuitive judgments which, though in every case relatively true, are nevertheless in many absolutely and demonstrably false. Having, as he conceived, established a principle indisputably certain, he was prepared to admit, and, in point of fact, never suffered himself to doubt or to question, any consequence, however startling, which might be logically deduced from it. His very errors, therefore, are the direct and necessary result of a rigid adherence to this principle, and of the precision with which he reasoned from the primary assumption to its consequences.

In the second or physical part of his system, Epicurus borrowed from Democritus and Leucippus the idea of the atoms or monads, which he regarded as the ultimate principles of all things. These atoms, however, which had no other properties than those of hardness and gravity, and which were therefore totally distinct from the gases of every kind that form so prominent a part of the physics and chemistry of the moderns, soon fell into discredit with philosophers; and, notwithstanding the poetical embellishments which the hypothesis received from the genius of Lucretius, it continued to be treated as a subject more fitted for ridicule than reason, until Gassendi endeavoured to revive and restore it, but without success. The efforts of this philosopher, however, can scarcely be considered as having proved altogether fruitless, since Leibnitz in his theory of monads, Boscovich in his principles of corpuscular attraction, and still more recently Dr Dalton in his theory of definite proportions, which has effected a complete revolution in the nomenclature of modern chemistry, have, each in succession, adopted modifications of the original hypothesis, and thus brought within the precincts of science a doctrine once regarded as amongst the wildest extravagances of ancient philosophy. In fact, the atomic theory of modern times is founded upon the same general principle with the hypothesis promulgated by Democritus, taught by Leucippus, and afterwards adopted by Epicurus; namely, that matter, so far from being infinitely divisible, is resolvable by division, decomposition, or analysis, into certain ultimate or primordial elements or atoms, which, again, enter synthetically, in certain definite proportions, into the constitution or composition of all things. And thus it is that the grand cycle of decay and reproduction, observable in the operations and changes which take place in the material world, may also be detected in the history of philosophical systems; they rise, decline, disappear, and are reproduced by the silent working of causes too remote to be discovered or appreciated by us; they have their various phases and occultations, even whilst they remain within the sphere of our observation; and when they altogether disappear from our view, and seem to be for ever lost, it is only to return, after having rounded their apogee, and to present nearly the same aspect as before.

With regard to the third or ethical part of this system, morality, according to Epicurus, is entirely founded upon utility. Man is placed upon earth to seek or pursue his own happiness or good, and he finds it only in a calm and tranquil life. The sage is ever upon his guard against the passions which might disturb his peace. Physical pleasure consists in the satisfaction of our natural wants; but the less trouble we take to ensure this satisfaction, the fewer privations we will be exposed to, and the greater will be our immunity from reverses of fortune. To abstain in order to enjoy, was accordingly the grand maxim of this philosopher. The happiness of individuals depends upon, and forms part of, the general happiness, from which, therefore, it can never be separated. This is his leading principle; and hence the essence of his ethical system consists in inculcating the *maxima felicitas*, or the greatest happiness of the greatest number. It has indeed been vulgarly alleged that Epicurus made the supreme good to consist in pleasure; and many persons persist in thus representing his doctrine, without giving themselves the trouble to inquire what he understood by pleasure; a term which, as he applied it, differs in no degree from the wisdom of the Stoics, and the *maxima felicitas* of the modern school of Utilitarians, founded by Bentham, the great restorer of the Epicurean ethical philosophy. In the nomenclature of this system, whatever contributes to the happiness and well-being of man as a member of society, is denominated pleasure; nor, as the happiness of individuals is made to depend upon, and declared to be inseparable from, the general happiness, can the true meaning of the term be mistaken or misapprehended by any honest and intelligent inquirer. But those false Epicureans, who limited the import of the word to mere sensual indulgence, and reasoned as if Epicurus himself had recognised this acceptation, did great injury to the sect, which they brought into unmerited discredit and odium. We accordingly find that they were banished from Rome in the time of the republic, and also, at different intervals, from a number of other cities. But the school always subsisted at Athens, where it remained in the time of Lucian; and Numenius, his contemporary, remarks, with an evident feeling of regret, that the Epicureans had preserved in all its purity the doctrine of their master, whilst that of Plato had been greatly altered and corrupted. The Stoics appropriated several of the maxims, and adopted the most remarkable apophthems of Epicurus, which are expressed, with much spirit, in a brief, sententious style; and the principal charm of Seneca's letters to Lucilius consists in the freedom and extent to which he has borrowed from the same source.

It is very difficult to discover the real opinion of Epicurus respecting the divinity. Cicero assures us that the philosopher spoke of the Supreme Being in terms the most sublime, and that he recommended piety to his disciples. It may no doubt be alleged that this was done in order to conform to the popular belief, and that no safe conclusion can be drawn, as to the opinion really entertained by the philosopher, from mere generalities, or a convenient and safe recommendation. But, on the other hand, in his letter to Menecius, Epicurus expresses himself thus: "The gods are not such as the vulgar believe; and the impious man is not he who rejects the gods of the multitude, but he who attributes to the gods the opinions of the multitude." These expressions, if they had been known, would have been sufficient to ensure to their author the honours of persecution. But, whilst it is evident that Epicurus was not actuated by mere prudence in making the belief of a God one of the principal dogmas of his philosophy, it must at the same time be admitted that his other opinions respecting the gods rendered this belief useless. For he regarded them as beings perfectly happy, impassible, and in no degree concerned about, or disposed to intermeddle with, human affairs,—as alike indifferent to, and incapable of, being affected by the good or evil of this world; and thus destroyed at once a providence, and the hope of future recompense or punishment. To this opinion, certainly one of the most discouraging and disastrous which can be maintained or promulgated, may be mainly ascribed the charge of atheism which was early preferred, and often subsequently reiterated, against this amiable and virtuous philosopher, whose life was as remarkable for its moral purity as those of some of his pretended followers were for their dissoluteness and profligacy.

EPICURUS, one of the most celebrated philosophers of antiquity, was descended of an illustrious family, that of the Philaides, which derived its origin from Philæus, grandson of Ajax. Neocles, his father, resided in Gargettium, a borough of Attica; but finding himself ill provided in point of fortune, he passed into the island of Samos, when the Athenians sent a colony thither, in the year 352 before Christ. As Diogenes Laertius fixes the birth of Epicurus in the year 341 before Christ, it is therefore probable that the philosopher first saw the light at Samos, and not at Gargettium, as is commonly supposed. In his early youth he is said to have followed his mother, who appears to have been an itinerant sorceress, reading the formularies of exorcism and expiation, whilst she performed the ceremonies usual on such occasions; but as he advanced in years he assisted his father in keeping a school, which the latter had established at Samos. At the age of fourteen Epicurus began to devote himself to philosophy. He at first attended Pamphilus, one of the disciples of Plato, and Nausiphanes, of the school of Democritus; not the disciple of Pyrrho, as Diogenes Laertius affirms, Pyrrho having been the contemporary of Epicurus. But the lessons he received from these teachers did not satisfy his mind; and having applied himself to the study of the writings of Democritus, he made great progress in philosophy, and soon thought himself in a condition to form a new sect. At the age of eighteen he proceeded to Athens, but he sojourned there only a short time, by reason of the troubles which ensued after the death of Alexander. He then repaired to his father's at Calophon, in Ionia, whence he afterwards went to Mitylene and Lampsacus, where he began to profess his new principles of philosophy. Having attracted a great number of disciples, amongst whom were the three brothers Neocles, Cheredemus, and Aristobulus, he returned with them to Athens in the year before Christ 309; and having there purchased a garden for eighty minæ, or L.288 sterling, he immediately commenced teaching his philosophy. All the world was not admitted to his lessons; but his disciples, in imitation of the Pythagoreans, formed a sort of community by themselves. Nevertheless, he did not recommend or encourage a community of goods, which he considered as calculated to excite distrust; but each paid a portion of the general expense, which, however, was inconsiderable, as they were content with the simplest fare. The most perfect union reigned amongst them, and indeed subsisted undisturbed long after the death of Epicurus. Cicero says that the Epicureans of his time still lived in common, and in the best understanding with one another. Women were even admitted into this society; and amongst its most celebrated disciples are mentioned Leontium, courtezan of Athens, and Themista, wife of Leontius of Lampsacus. As Epicurus never taught in public, the sect was little celebrated during his lifetime; but after his death, when his writings became generally known, the doctrine therein taught was warmly attacked by the Stoics, who did not blush even to have recourse to the most atrocious calumnies. Diotimus the Stoic went so far as to fabricate, in the name of Epicurus, fifty letters addressed to courtezans, in which the philosopher is made to express himself in the most obscene manner; but Chrysippus himself bears testimony to the blameless conduct and manners of Epicurus; and although the latter alleged that this was not the result of philosophy, but attributable solely to coldness and insensibility of temperament, it is certain that his life was wholly free from those vices with which his enemies have reproached him. For a short account of the system, canonical, physical, and ethical, taught by this philosopher, see EPICUREAN PHILOSOPHY. Epicurus died of the stone in the seventy-second year of his age. He was never married; not that he blamed marriage, for he taught that a wise man ought to marry and have children; but as he was of a feeble constitution, and seldom enjoyed good health, he did not think it incumbent on him to observe the maxim which he inculcated on others. By his will, which Diogenes Laertius has preserved, he bequeathed his garden and a house which he had at Melitus to Hermachus his successor, and to those who should after him be at the head of his school, as long as it should subsist, in order that his followers might assemble on the spot where his system was first taught. His memory was held in veneration by his disciples, among whom the anniversary of his birth was celebrated as a festival; they had his portrait engraved on their rings and on their cups, as well as placed in their chambers; and they never spoke of him but with the greatest respect. In the number of Greek manuscripts discovered at Herculaneum have been found several of the works of Epicurus, the unravelling of which, however, has as yet been only partially effected. Some fragments of the second book of his treatise *On the Nature of Things* were published at Naples in 1814. No one has better developed the philosophical system of Epicurus than Gassendi in his *Syntagma de Vita et Moribus Epicuri*, lib. viii. Lyons, 1647. See also Durondel, *Vie d'Epicure*, Paris, 1679; Coutures, *La Morale d'Epicure*, Paris, 1685; *Apologie pour Epicure*, and *Discours sur Epicure*, Paris, 1651 and 1684, in 12mo.

EPICYCLE, in the ancient astronomy, a little circle whose centre is in the circumference of a greater circle: or it is a small orb or sphere, which being fixed in the deferent of a planet, is carried along with it; and yet, by its own peculiar motion, carries the planet fastened to it round its proper centre.

It was by means of epicycles that Ptolemy and his followers solved the various phenomena of the planets, but more especially their stations and retrogradations.

EPICYCLOID, in *Geometry*, a curve generated by the revolution of the periphery of a circle, along the convex or concave side of the periphery of another circle.

EPIDAMNUS, afterwards called by the Romans DYRRHACHIUM, a city of Illyria, on the coast of the Adriatic, founded by a colony from the island Corcyra, under the command of Phalius, a native of Corinth, 629 years B. C. according to Eusebius. The lofty and precipitous peninsula on which it was built seems to have been called Dyrrhachium; and as the last syllable of Epidamnus was significant of ill omen to the Romans, that superstitious people

Epidaurus.

were probably induced to change it for the name applied by the Greeks to the peninsula. There seems no good reason to believe that the site of the more modern town was different from that of the ancient. Epidamnus became at a very early period of considerable importance: its intimate connection with the rich republics of Corcyra and Corinth excited in its citizens a spirit of commercial enterprise; and it was not long before they rivalled the most celebrated of the cities of Greece in the extent of their trade and the magnitude of their undertakings. Epidamnus continued to prosper until it became a prey to domestic feuds and civil broils. Its constitution was originally aristocratic; a single magistrate formed the head of the administration; and the phylarchs (φυλαρχαι) composed a species of council. These phylarchs were afterwards replaced by a senate (βουλη) chosen on democratic principles. It was the contest between the popular party at Epidamnus and the nobles that produced the Peloponnesian war. Corcyra refused to interfere, and the Epidamnians proceeded to make their application to the Corinthians, who felt nowise disinclined to increase their own power at the expense of the Corcyreans. The aid furnished by Corinth soon re-established order and tranquillity; but the Corcyreans, at no time on good terms with that city, felt highly indignant that it should have interfered with what they considered as their own peculiar property. They sent orders to the Epidamnians to receive back the nobles whom they had banished, and to cause the Corinthians to evacuate the city; but as no attention was paid to the demand, they equipped a fleet, and, in conjunction with a body of Illyrians, besieged the town, which, in a few days, was compelled to surrender. This was the beginning of the Peloponnesian war. Of the subsequent history of Epidamnus we know but little until we find it under the protection of the Romans, to whom it adhered faithfully, both in the Illyrian and Macedonian wars.

At a later period it became the scene of contest between Pompey and Cæsar; but for a detailed account of these transactions we must refer the reader to the Commentaries of Cæsar himself. From this time it became much frequented by the Romans, from being situated at the commencement of the great Egnatian Road, which led through Macedonia to the provinces of the east. Here it was that Cicero landed on his banishment from Italy; and he speaks in high terms of commendation of the kind treatment which he received from its inhabitants. At the end of the fourth century Dyrrhachium became the capital of the newly established province of Epirus Nova; and it is now called *Durazzo*, which is an insignificant village, rendered unhealthy by its vicinity to marshes.

EPIDAURUS, a city of Argolis, in the Peloponnesus, situated in a recess of the Saronic Gulf, open to the north-east, and backed by high mountains, was founded probably by Carians, and afterwards joined by a colony of Ionians from Attica. It was at first subject to Argos; but on the return of the Heraclidæ and Dorians to the Peloponnesus, an independent kingdom was established, which extended over the whole of this small peninsula. We find its king Procles engaged in war with Periander of Corinth. In the Persian war it sent ten ships to the common fleet at Salamis, and eight hundred heavy-armed men to Platæa· and in the Peloponnesian war it always appears as the determined opponent of Argos, and the ally of Sparta, successfully resisting the Argives when besieged by them after the battle of Amphipolis. In the time of Augustus the circumference of its walls was no more than fifteen stadia; whence it appears that Epidaurus was even at that time reduced to the promontory where are now to be seen, in many parts, the foundations of Hellenic walls along the edge of the cliffs. A small neighbouring village is still called *Pidhavro*.

Epidaurus was chiefly remarkable for the temple and sacred grove of Æsculapius, one of the most renowned places in Greece for its sanctity, riches, and the splendour of the sacred offerings which adorned it. It was at the distance of five miles from the city, and surrounded by a semicircle of steep hills. The place is still called *Sto Ierò*, which means the temple, or sacred place. It contained a statue of the god, wrought in gold and ivory, by Thrasymedes of Paros, and about half the size of the Jupiter Olympius at Athens. Æsculapius was seated on a throne, holding a staff in one hand, whilst the other rested on the head of a serpent, and a dog lay at his feet. Beside the temple was the dormitory of those who came to supplicate the god; and near it the Tholus, a circular building of white marble, built by Polycletus of Argos. But the most remarkable building was the theatre, which, though inferior in size and ornamental decoration to those of the Romans, far excelled them in the beauty of its workmanship and the harmony of its proportions. This temple was the most fashionable place of resort for Grecian invalids seeking relief from a change of air, of place, or of medical treatment. Hither they flocked from every part of the country, to place themselves under the care of the servants of Æsculapius; and those who were healed were in the habit of recording their cures with inscriptions in different parts of the temple.

Considerable remains of the temple and adjoining buildings are still to be seen. "There exists a part of the foundations, and some remains of the circular cell of the Tholus, with defaced inscriptions. But the most remarkable ruin at Iero is the theatre: though no traces of the proscenium remain, and many of the seats made of white marble are displaced, it is in better preservation than any other theatre in Greece, except that which exists near Trametzus in Epirus, not far from Joannina. The orchestra must have been about ninety feet in length, and the entire theatre about 370 in diameter. Thirty-two rows of seats still appear above ground in a lower division. The theatre, when complete, was capable of containing 12,000 spectators." Leake's *Travels in the Morea*, vol. ii. p. 424, London, 1830.

EPIDEMIA, in Grecian antiquity, festivals observed in honour of Apollo and Diana, at the stated seasons when those deities, who could not be present everywhere, were supposed to visit different places, in order to receive the vows of their worshippers.

EPIDEMIC, among physicians, an epithet applied to those diseases which at certain times are popular, attacking great numbers at or near the same time. See MEDICINE.

EPIDERMIS, in *Anatomy*, the cuticle or scarf-skin. See ANATOMY. The word is formed of the Greek επι, *on*, *over*, and δερμα, *skin*.

EPIDICASIA, amongst the Athenians. Daughters inheriting their parents' estate were obliged to marry their nearest relation; which gave occasion to persons of the same family to go to law with one another, each pretending to be more nearly allied to the heiress than the rest. The suit was called επιδικασιας δικη; and the virgin about whom the relations contested, επιδικος.

EPIDOTÆ, certain deitics who presided over the growth of children. They were worshipped by the Lacedæmonians, and chiefly invoked by those who were persecuted by the ghosts of the dead, or spectral apparitions.

EPIGONI, the sons and descendants of the Grecian heroes who were killed in the first Theban war. The war of the Epigoni is famous in ancient history. It was undertaken ten years after the Theban war. The sons of those who had perished in that contest resolved to avenge the death of their fathers, and marched against Thebes, under the command of Thersander, or, according to others, of Alcmæon the son of Amphiaraus, about 1307 years before Christ. The Argives were assisted by the Corinthians and the people of Messenia, Arcadia, and Megara. The Thebans had engaged all their neighbours in their quarrel, as in one common cause. The two hostile armies met on the banks of the Glissas, and a battle ensued. The combat was obstinate and bloody; but victory declared for the Epigoni, and some of the Thebans fled to Illyricum with Leodamas their general, whilst others retired into Thebes, where they were soon afterwards besieged and forced to surrender. In this war Ægialeus was the only person of note who was killed; and in the former his father Adrastus was the only individual of this description who escaped alive. This whole war, as Pausanias observes, was written in verse; and Callinus, who quotes some of the verses, ascribes them to Homer, an opinion which has been adopted by many writers. "For my part," continues the geographer, "I own, that next to the Iliad and Odyssey of Homer, I have never seen a finer poem." The *Epigoniad* of Wilkie is a modern poetical celebration of the same story. The descendants of the veteran Macedonians, who served under Alexander the Great, and who had children by Asiatic women, were also called Epigoni.

EPIGRAM, in *Poetry*, a short poem in verse, treating only of one thing, and ending with some lively, ingenious, and natural thought or point. The word is formed of επιγραμμα, *inscription*, from επιγραφειν, *to inscribe* or *write upon*. See POETRY.

EPIGRAPHE, among antiquaries, denotes the inscription of a building, pointing out the time when, the persons by whom, and the uses for which, it was erected.

EPILOGUE, in *Oratory*, the end or conclusion of a discourse, ordinarily containing a recapitulation of the principal matters before delivered.

EPILOGUE, in the *Drama*, a speech addressed to the audience after the play is over, by one of the principal actors, and usually containing some reflections on certain incidents in the play, especially those in the part of the person who speaks it, together with somewhat of pleasantry, intended to compose the passions raised in the course of the representation; a practice which is ridiculed by the *Spectator*, and compared to a merry jig upon the organ after a good sermon, in order to wipe away any impressions that might have been thereby produced, and to send the people away just as they came.

EPIMENIDES, a native of Gnossus in Crete, who seems to have flourished about 594 B. C. and of whom we have several very extraordinary accounts. Being probably a man anxious to distinguish himself, he was not long in perceiving that the readiest way to obtain the object he had in view was to work on the love of the supernatural, a feeling inherent in the minds of an ignorant people. Accordingly we are told that he retired from all intercourse with his countrymen, and no doubt devoted himself to the acquisition of that knowledge which enabled him to act the part which he had chalked out for himself. When he imagined his name forgotten, he re-appeared with his hair and beard long and matted, and spread a report that he had slept upwards of two hundred and ninety years. Who does not recognise in this the story of the seven sleepers? In accordance with this spirit of charlatanry, he pretended to the gift of prophecy, and to intimate converse with the gods. Yet under all this outward garb of fanaticism he seems to have concealed a profound knowledge of mankind, and to have employed the influence he had acquired in obtaining the sanction of the Cretans to a code of laws constructed on just and sound principles. His fame became so widely spread, that Solon, under pretence of purifying the city of Athens from the blood shed in consequence of civil feuds and dissensions, determined to make use of his influence to prepare the way for the laws which he wished to introduce. A vessel was equipped, and Epimenides having acceded to the invitation given him, assisted in purifying the city, and at the same time prepared the way for the legislation of Solon. He wrote several works, of which the most considerable was a poem on the expedition of the Argonauts; but none of these has come down to us. His life has been written by Diogenes Laertius, but that writer is too credulous to admit of our placing much dependence on the facts he states. See Cic. *Div.* i. 18, and *Leg.* ii. 2; Val. Max. viii. 5; Suidas; Plato *De Leg.*; Pausanias; also, for his age, Vossius *De Hist. Græc.* Lug. Bat. 1651; Fabricius, *Biblioth. Græc.* i. 6.

EPIMETHEUS, a son of Japetus and Clymene, one of the Oceanides, who inconsiderately married Pandora, by whom he had Pyrrha, the wife of Deucalion. He had the curiosity to open the box which Pandora had brought with her, and thence issued the train of evils which from that moment have never ceased to afflict the human race. Hope was the only redeeming ingredient which remained at the bottom of the box, not having had sufficient time to escape; and she it is alone who comforts men under misfortunes. Epimetheus was changed into a monkey by the gods, and sent into the island Pithecusa.

EPINAL, an arrondissement of the department of the Vosges, in France, extending over 550 square miles, and divided into five cantons, which are subdivided into 116 communes, with 68,610 inhabitants. The capital, a city of the same name, is situated on the river Moselle, which divides it into two parts. It is a well-built place, containing 1100 houses and 7820 inhabitants, who carry on some trade in earthenware, cotton goods, paper, and leather. Long. 6. 29. E. Lat. 48. 22. N.

EPIPHANIUS, ST, an ancient father of the church, born at Besanducan, a village in Palestine, about the year 332. He founded a monastery near the place of his birth, and presided over it. He was afterwards elected bishop of Salamis, when he took part with Paulinus against Meletius, and ordained in Palestine Paulinian, the brother of St Jerome, on which a contest arose between him and John bishop of Jerusalem. He afterwards called a council in the island of Cyprus, in which he procured a prohibition of the reading of Origen's writings, and made use of all his endeavours to prevail on Theophilus bishop of Alexandria to engage St Chrysostom to declare in favour of that decree; but not meeting with success, he himself proceeded to Constantinople, where he refused to have any conversation with St Chrysostom, and formed the design of entering the church of the apostles to publish his condemnation of Origen. Being informed, however, of the danger to which he would be exposed, he resolved to return to Cyprus, but died at sea in the year 403. His works were printed in Greek at Basil, 1544, in folio, and were afterwards translated into Latin, in which language they have often been reprinted. Petavius revised and corrected the Greek text with the aid of two manuscripts, and published it together with a new translation at Paris in 1622. This edition was reprinted at Cologne in 1682.

EPIPHANY, a Christian festival, otherwise called the *Manifestation of Christ to the Gentiles*, observed on the sixth of January, in honour of the appearance of our Saviour to the three magi or wise men, who came to adore him and bring him presents. The feast of epiphany was not originally a distinct festival, but formed part of that of the nativity of Christ, which being celebrated twelve days, the first and last of which were high or chief days of solemnity, either of these might properly be called *epiphany*, as that word signifies the appearance of Christ in the world.

The word in the original Greek, επιφανια, signifies *appearance* or *apparition*, and, as some critics think, was applied to this feast, on account of the star which appeared to and guided the magi. St Jerome and St Chrysostom take the epiphany for the day of our Saviour's baptism, when he was declared to men by the voice, *Hic est filius meus dilectus, in quo mihi complacui*, this is my beloved Son, in whom I am well pleased; and accordingly it is still observed by the Copts and Ethiopians in this view. But others contend that the feast of Christmas, or the nativity of our Saviour, was held in different churches on this day, which had the denomination *epiphany* or *appearance*, by reason of our Saviour's first appearance upon earth at that time. And it must be allowed that the word is used amongst the ancient Greek fathers, not to signify the appearance of the star to the magi, but that of our Saviour to the world; in which sense St Paul uses the word *epiphania* in his second epistle to Timothy (i. 10.)

EPIRUS, a country to the north-west of Greece, along the coast of the Ionian Sea, bounded on the north by the Ceraunian Mountains, on the south by the Ambracian Gulf, and separated on the east and north-east from Thessaly and Macedonia by the lofty range of Pindus. This extensive country was known in the earlier ages of the world under no general name; it was probably the inhabitants of the numerous islands along its coasts who first applied to it the appellation of Epirus, answering to the English term mainland, in order to distinguish it from the islands which they themselves inhabited. It included within its bounds several nations, the most powerful of whom were the Molossi, whose chief town was Dodona, famous for the oracle and temple of Jupiter; the Thesproti, who had for their capital Buthrotum; and the Chaones, who dwelt in the valleys of the Ceraunian Mountains. All these tribes are considered as having been of Pelasgic origin. Though allied by blood with the Greeks, they were always regarded as barbarians, and Ambracia as the last city in Greece. The ancient buildings, institutions, and religious worship of the Epirotes, are also manifestly of Pelasgic origin.

The kings of Epirus pretended to be descended from Pyrrhus, son of Achilles, who settled in this country after the taking of Troy, and transmitted his kingdom to Molossus, his son by Andromache; but the early history of the kings of the Molossi is involved in much obscurity. Admetus sat on the throne of Epirus, 480 B. C. at the time of the invasion of Greece by the Persians, and he remained neutral till their defeat, when he solicited an alliance with the Athenians. This was refused chiefly through the persuasion of Themistocles; yet Admetus was generous enough to forget this circumstance when Themistocles was banished, 471 B. C. by his ungrateful countrymen, and received him with every mark of respect and esteem.

Admetus was succeeded by his son Tharymbas or Arymbas I. about 429 B. C., but was still so young that he was placed, by a decree of the people, under the guardianship of Sabylinthus, prince of Atintania. He seems to have been a wise and prudent monarch, who attempted to introduce a regular form of government among a wild and a lawless people. Alcetas is the next king of Epirus mentioned in history, and he reigned about 385 B. C. Being driven from his throne by his subjects, he fled to Syracuse, and with the assistance of Dionysius was soon afterwards re-established. Neoptolemus his son reigned but a short time, and left the crown to his brother Arymbas II. about 360 B. C. who encouraged literature and the arts, governing his kingdom with prudence, equity, and moderation. It was to him that Xenocrates of Chalcedon dedicated the four books which he had composed on the art of governing. This prince educated with the greatest care the children of his brother. He married Troas, one of his nieces, and gave the other, Olympias, in marriage to Philip of Macedon, who had by her Alexander the Great. On his death, 342 B. C. he was succeeded by his nephew Alexander, brother of Olympias. This prince was put in possession of the throne of his uncle by the aid of his brother-in-law Philip, who afterwards gave him in marriage his daughter Cleopatra. It was at the celebration of these nuptials at Edessa that the king of Macedonia was assassinated.

Alexander was the first prince who raised the character and reputation of his country amongst foreign nations. Having been applied to by the Tarentines for assistance against the Samnites and Lucanians, he passed into Italy with a considerable force, made a descent at Pæstum, 332 B. C., a city near the mouth of the river Silarus, and reduced under his dominion several cities of the Lucani and Brutii. In his second attack upon Italy he was surrounded by the enemy, defeated, and slain, near the city Pandosia, in the territory of the Brutii.

Œacides the son of Arymbas II. succeeded to Alexander, and espoused the cause of Olympias against Cassander; but his soldiers having mutinied, dethroned him, though he was in a short time reinstated. He was killed the same year, 313 B. C., in a battle against Philip, brother of Cassander. This prince had by his wife Phthia, the celebrated Pyrrhus, and two daughters, Deidamia and Troas, of whom the former married Demetrius Poliorcetes. His brother Alcetas, who succeeded him, continued the war with Cassander till he was defeated, and his dominions were overrun by the enemy. He was afterwards put to death by his rebellious subjects 295 B. C. The name of Pyrrhus, who now ascended the throne, sheds a lustre on the annals of Epirus, and gives to its history an importance which it would never have otherwise possessed; but for a detailed account of his life we must refer to the article PYRRHUS.

Alexander, in 272 B. C., succeeded his father Pyrrhus, when he attempted to seize on Macedonia. He defeated Antigonus Gonatas, but was himself shortly afterwards driven from his kingdom by Demetrius, son of that prince. He recovered it, however, and spent the rest of his reign in peace. At the expiration of two other insignificant reigns the family of Pyrrhus became extinct, upon which the inhabitants of Epirus changed the form of their government, electing annually a prætor in a general assembly of the nation held at Passaron, a city of the Molossi. Epirus imprudently espoused the cause of Perseus in his war against the Romans, when he was defeated and taken prisoner 168 B. C.; and it was exposed to the unrelenting fury of the Romans, who destroyed in one day seventy-three cities, and carried away the principal inhabitants to Rome. It never recovered from this fatal blow. At the dissolution of the Achæan league, 146 B. C. this country became part of the province of Macedonia under the name of Vetus Epirus, in order to distinguish it from Nova Epirus, which lay to the east.

On the division of the empire it became the inheritance of the emperors of the East, and remained under them until the taking of Constantinople by the Latins, in 1204, when Michel Comnenes seized on Ætolia and Epirus. On the death of Michel, in 1216, these countries fell into the hands of his brother Theodore. Charles, the nephew of Theodore, and the last prince of this family, having died without legitimate heirs, Epirus and Acarnania were left to his natural children. Amurath II. stripped them of this inheritance. In 1443, Scanderberg, king of Albania, made himself master of a considerable part of Epirus. But on his death it fell into the power of the Venetians, from whom it passed to the Turks, who possess it at present under the name of Albania.

EPISCOPACY, that form of church government in which diocesan bishops are established, as distinct from and superior to priests or presbyters. We have already observed, that from a very early period the ministers of religion have been distinguished into different orders, and that it has been much controverted whether the distinction be of divine or human right; whether it was settled in the apostolic age, or only adopted afterwards. (See Bishop.) This controversy commenced soon after the Reformation, and has been agitated with great warmth between the Episcopalians on the one side, and the Presbyterians and Independents on the other. Amongst the Protestant churches abroad, those which were reformed by Luther and his associates were in general episcopal; whilst such as follow the doctrines of Calvin have for the most part dispensed with the order of bishops, as being either unnecessary or unattainable. In England, however, the controversy has been considered as of greater importance than on the continent; for it has there been strenuously maintained by one party that the episcopal order is essential to the constitution of the church; and by the others, that it is a pernicious encroachment on the rights of Christians, for which there is no warrant or authority in Scripture. Though the question has for some time lain almost dormant, and though we have no desire to revive it, yet as a work of this kind might perhaps be deemed defective, did it contain no account whatever of a controversy which has employed some of the ablest writers of the past and present times, we shall give a fair though short view of the chief arguments by which the advocates of each contending party have endeavoured to support their own cause, leaving it to our readers to judge where the truth lies. See Independents and Presbyterians.

The Independent maintains, that under the gospel dispensation there is nothing which bears the smallest resemblance to an exclusive priesthood; that Christ and his apostles constituted no permanent order of ministers in the church; but that any man who has a firm belief in revelation, a principle of sincere and unaffected piety, a capacity for leading devotion and communicating instruction, and a serious inclination to engage in the important employment of promoting the everlasting salvation of mankind, is in all respects a regular minister of the New Testament, especially if he have an invitation to the pastoral office from some particular society of professing Christians.

Against this scheme, which supposes the rights and privileges of all Christian men to be equal, and which acknowledges no authority in the church excepting that which is derived from election by its members, the Protestant Episcopalian argues in the following manner: He admits, as an undoubted truth, that Christ gave to none of his followers authority or jurisdiction of such a nature as could interfere with the rights and duties of the civil magistrate; that he never conferred upon them what he disclaimed for himself, when, before Pilate, he declared that his kingdom was not of this world. He maintains, however, that Christ did confer upon his immediate followers, and does still confer upon their successors in the ministry, authority and jurisdiction of a specific nature over other Christians; and that neither during our Saviour's abode upon earth, nor during the period of the government of the church by apostles, nor in the age immediately succeeding these, did there exist an absolute equality among believers.

During our Saviour's ministry, it will be allowed that all power resided in him; and it is important to observe, that even then, before believers were constituted a church, parity was abolished by the ordinance of Jesus himself, in the appointment of the twelve apostles and the seventy disciples. And when the divine Founder of Christianity was making preparations for the maintenance of his religion after his departure hence, he did not abolish the distinction which he had previously instituted, but granted to the twelve apostles a still wider commission, a still more decided supremacy over the ordinary members of the church. "As my Father hath sent me," said he, "even so send I you. And when he had said this, he breathed on them, and said unto them, receive ye the Holy Ghost: whose soever sins ye remit, they are remitted unto them, and whose soever sins ye retain, they are retained." (John, xx. 21, 22, 23.) "All power is given unto me in heaven and in earth. Go ye, therefore, and teach all nations, baptizing them in the name of the Father, and of the Son, and of the Holy Ghost, teaching them to observe all things whatsoever I command you; and lo, I am with you alway, even unto the end of the world." (Matt. xxviii. 18, 19, 20.) Now the Episcopalian maintains that men who had received this commission could not be on a footing of equality as to ecclesiastical privileges with the great body of believers, who had no commission whatsoever.

If, however, all this be granted, and still the *permanence* of the commission be denied, the Episcopalian refers to our Lord's concluding words, "I am with you alway, even unto the end of the world;" and asks how Christ could be with the commission to the end of the world, if the commission itself was to last only for one generation. But, further than this, he refers to the acts of the apostles, as furnishing abundant evidence that they understood it to be the will of Christ that there should be a perpetual succession of privileged officers in the church. For, in the first place, the vacancy occasioned by the death of Judas was immediately filled by the appointment of Matthias; then a new order of Christian ministers was introduced under the name of deacons; afterwards Barnabas and Saul were ordained to be apostles; and finally, as the number of Christian congregations increased, a race of ministers superior to the deacons was instituted, to administer the sacraments, and to preside in the religious assemblies. To imagine that these were elected by the laity, and derived their authority from that election, could scarcely be credited, even if we possessed no evidence to the contrary. But St Paul (Eph. iv. 11) asserts, that when Christ ascended up on high, "*He* gave some apostles, and some prophets, and some evangelists, and some pastors and teachers;" that is to say, *he* commissioned the apostles, and empowered *them* to commission the inferior officers.

With respect to the age immediately succeeding the apostolic, we cannot of course refer to Scripture, but must have recourse to the records of primitive antiquity. And in referring to the *Fathers* for the historical fact, the Episcopalian claims for them nothing more than sufficient honesty to tell the truth when there existed no temptation to commit falsehood, or sufficient sense to abstain from a falsehood which it was impossible should be credited by any of their contemporaries. Now, of the earliest Christian writers, of those called apostolic fathers, because they are believed, on good grounds, to have been contemporaries and companions of the apostles, three, namely, Clement of Rome, Ignatius, and Hermas, explicitly state the existence of different orders of officers in the church, to whom great honour and obedience was due from the laity; whilst the remaining two, Polycarp and Barnabas, do not touch upon ecclesiastical polity. Further than this it is unnecessary to descend, as every one now admits that in the age succeeding this, diocesan episcopacy prevailed over the Christian world, and continued undisputed till the Reformation.

Against this historical argument it may be urged, that the commission to the apostles was " to go and teach all nations, baptizing them in the name of the Father, the Son, and the Holy Ghost;" and that consequently a system which confines the right of preaching and baptizing to their successors in a particular *order* appears inconsistent with the wisdom and the goodness of God; as by such an economy an intolerable dominion would be established over the souls of men, and the very purpose for which the Saviour died might be defeated by the caprice of an ignorant or designing priesthood. To this objection the Episcopalian replies, that under the Mosaic law sacrifice was necessary for the expiation of sin, but that in many most important cases this expiation could be effected only by the instrumentality of a priest; that, in short, the objection, if it have any weight, weighs with equal force against the wisdom and justice of Providence in the ordinary government of the world. In every thing, he observes, that is valuable, whether of a temporal or a spiritual nature, mankind are subjected to mutual dependence; baptism must be conferred, and knowledge must be communicated, by some human being; and it is just as easy to imagine the whole *human race*, as the whole *clerical order*, unfaithful to their obligations.

The Episcopalian having by arguments of this nature attempted to prove that Christ did institute a *permanent order of ministers* in his church, proceeds, in the next place, by an inquiry of the same nature, to prove that this order was not *single*, but *threefold*. In the former inquiry he was united with the *Presbyterian* against the *Independent;* he has now to answer the arguments of the Presbyterian, who maintains that originally the Christian church contained no office higher than that of *presbyter* or *elder;* and, in opposition to him, the Episcopalian maintains that Christ and his apostles instituted divers orders in the church, of which that of *bishops* with authority over *presbyters*, and with the *exclusive right of ordination*, was the highest.

In behalf of the Presbyterian plea it is urged, that the titles of *bishop* and *presbyter*, being in the New Testament indifferently given to the same persons, cannot be the titles of distinct ecclesiastical officers; which appears still more evident from the ordination of Timothy, who, although he was the first *bishop* of Ephesus, received his episcopal character by the imposition of the hands of the *presbytery*. That one and the same man is, in the New Testament, styled sometimes a *bishop* and sometimes a *presbyter*, cannot be denied; but although every apostolic bishop was therefore undoubtedly a presbyter, it does not of course follow, says the Episcopalian, that every presbyter was likewise a *bishop*. In the *Old* Testament, Aaron and his sons are without any discrimination of order frequently styled *priests;* and in the *New*, both St Peter and St John call themselves *presbyters*, as St Paul, upon one occasion, styles himself a *deacon*, διακονος (Eph. iii. 7): yet no man ever supposed those apostles to have been such ecclesiastical officers as modern presbyters and deacons; and it is universally known, that in the Jewish priesthood there were different orders, and that Aaron was of an order superior to his sons. This being the case, the presbyters, by the laying on of whose hands Timothy was made a bishop, *may have been* of the same order with St Peter and St John; and if so, it follows that his ordination was *Episcopal*. At all events, we are certain, continues the advocate for Episcopacy, that it was not in the modern sense of the word *Presbyterian;* for the gift, which in the first epistle is said to have been " given by prophecy *with* the laying on of the hands of the presbytery," is in the second said to have been " in him *by* the putting on of the hands of St Paul." And here it is worthy of observation, that the preposition used in the former case is μετα, which signifies *concurrence* rather than instrumentality; but *that* in the latter is δια, which, as every Greek scholar knows, is prefixed to the *instrumental cause* by which any thing is effected; so that whatever may have been the order of the presbyters who *concurred*, St Paul appears to have been the *sole* ordainer. But by the confession of all parties, St Paul was a bishop in the highest sense in which that word is ever used; and the powers of the episcopate not being parcelled out among various partners, of whom each possessed only a share, the imposition of his hands was sufficient for every purpose which could have been effected by the hands of the whole college of apostles.

It appears, therefore, that from the promiscuous use of the titles *bishop* and *presbyter*, and from the *ordination of Timothy*, nothing can with any certainty be concluded on either side of this celebrated question. But if, instead of resting on mere *words*, which, when taken alone and without regard to the context, are almost all of ambiguous signification, we attend to some important *facts* recorded in the New Testament, the Episcopalian thinks we shall discover in these sufficient evidence that the government of the primitive church was Episcopal.

During our Saviour's stay upon earth, it is undeniable that he had under him two distinct orders of ministers, the twelve and the seventy; and after his ascension, immediately before which he had enlarged the powers of the *eleven*, we read of *apostles*, *presbyters*, and *deacons*, in the church. That the presbyters were superior to the deacons, and the apostles superior to both, is acknowledged by the supporters of presbyterian parity; but it has been said, that in Scripture we find no intimation that the apostolic order was designed for continuance. A Quaker says the same thing of water-baptism; and the Episcopalian observes, that it would be difficult to point out by what passage of Scripture, or what mode of reasoning, those who upon this plea reject the apostolic order of Christian ministers, could overthrow the principles upon which the disciples of George Fox reject the use of that rite which our Saviour instituted for the initiation of mankind into his church. They were the *eleven* alone to whom Christ said, " go ye therefore and teach all nations, baptizing them in the name of the Father, and of the Son, and of the Holy Ghost;" and hence, although we frequently find presbyters and deacons administering the sacrament of baptism, we must conclude, that as a *judge* administers justice by authority derived from his *sovereign*, so those *inferior officers* of the church administered baptism by authority derived from the *apostles*. Indeed, had they pretended to act by any other authority, it is not easily to be conceived how *their* baptism could have been the baptism instituted by Christ; for it was not with the *external washing*, by whomsoever performed, but with the *eleven* and their successors, that he promised to be " always, even unto the end of the world."

We have already noticed that the *eleven*, acting, as all orthodox Christians allow, by the extraordinary direction of the Spirit, never appear to have supposed that the commission with which they were invested was to terminate with them. On the contrary, they admitted Matthias, Barnabas, and Paul, to the name and authority of apostles, and Timothy and Titus to some office which, it is evident, was superior to that of either ancient or modern presbyters. Supposing it then granted that Timothy was commissioned by the apostle Paul not to found a church where the gospel had been hitherto unpreached, but to execute some office in one previously founded, the Episcopalian maintains that the directions given by the apostle could be addressed to none but a bishop, that is, to one possessing an ecclesiastical authority superior to that of presbyters. For in Timothy (iv. 2–6) we read, "I besought thee to abide still at Ephesus, when I went into Macedonia, that thou mightest charge some that they teach no other doctrine, neither give heed to fables and endless genealogies. Let the presbyters that rule well be counted worthy of double honour; especially they who labour in the word and doctrine. Against a presbyter receive not an accusation but before two or three witnesses. Them that sin rebuke before all, that others also may fear. Lay hands suddenly on no man, neither be partaker of other men's sins." Now, an individual right to direct *presbyters* as to the doctrine they preached, to receive accusations against them, to rebuke the offending, to confer authoritative approbation upon the deserving, and finally, to *ordain*, are exactly the offices which belong to a bishop. The right to perform these, if derived from an appointment by presbyters, would have constituted a *superintending presbyter;* but the right being conferred by apostolic authority, raised their professor to higher *order*, and this higher order is the Episcopal.

It is unnecessary to pursue the argument in the case of Titus, bishop of Crete, whose episcopacy is equally clear with that of Timothy; and if no other diocesan bishops are mentioned in the Acts or Epistles, we need not wonder when we reflect how little is said of the greater part of the apostolic body.

We perceive, then, that as far down as the history of the church is warranted in Scripture, there always existed *imparity* among the ministers of religion, and that the apostles ordained certain officers to superintend or be *bishops* over the presbyters. And when from the inspired penmen of the New Testament he proceeds to examine the succeeding writers of the Christian church, the Episcopalian finds such multiplied and concurring evidence of the apostolic institution of episcopacy, as he thinks it impossible to resist without denying the truth of all ancient history, and even shaking the pillars of revelation itself; for, "in the noble army of martyrs," the witnesses of the episcopal government of the church are earlier, and by far more numerous, than those who testify that the gospel of St Matthew was written by that apostle, or that the book of the Apocalypse is canonical Scripture. The authority of the Fathers indeed is at present very low; but should they be allowed to be as fanciful divines and as bad critics as their worst enemies are pleased to represent them, this would detract nothing from their evidence when they bear witness to the constitution of the church in their own times; for of their honesty there can be no doubt; and what the Episcopalian wants of them is only their testimony to matters of fact which fell under the cognizance of their own senses, and about which therefore they could not be deceived. It is here indeed chiefly that he triumphs over his antagonists. In the second and third centuries there was no general council, nor any Christian sovereign. A prelacy therefore, he urges, could not have been *universally* introduced, during that period, either by a concert among the clergy, or by the authority of the civil magistrate.

That at the close of the first or apostolic century the whole Christian world was *Presbyterian*, and that, as we know to have been the case, at the close of the second it was entirely *Episcopal;* that of the cause or progress of the change not a word should be mentioned by the contemporary writers; that whilst Episcopacy was a foul usurpation of the rights of Christ's flock, every Christian writer from Clement downwards should speak of it as a most excellent and even divine institution; that no single presbyter throughout the world should, as far as we know, have said a single word in defence of his insulted order; all this, the Episcopalian maintains, is so utterly improbable as to justify his regarding it as a fable, and one not very cunningly devised.

The candid Episcopalian, however, allows, that in the apostolic age there may have been some churches which at first had only bishops and deacons to perform the offices of religion; for when the number of disciples in any place was so small that they could all meet in one assembly, there was no necessity for any other order of ministers; but it appears that, from the very beginning, *bishops*, *presbyters*, and *deacons* were settled in all the *larger* cities of the Roman empire; and it was in those days an allowed maxim, that without a *bishop* there could be *no church*. The better to understand the original state and institution of episcopacy, it is necessary to observe, that the empire, which contained almost all the known part of the Christian world, was divided originally into provinces of two kinds, the one called *consular*, the other *prætorian*, of which the former were either larger, or of more political importance. In the reign of Augustus the consular provinces were placed under the direct control of the emperor, and were administered by *legates* generally of consular rank; whilst the prætorian were left under the control of the senate and people, and were governed by a *proconsul*, as Asia was. (See Acts, xix. 38.) There was still a third class of smaller provinces retained by the emperor, and governed in general by men of equestrian or even inferior rank, under the title of *procurators;* of these Judæa was one. A province comprehended the cities of a whole region; and in the age of the apostles each city was under the immediate government of certain magistrates within its own body, known by the name of βουλη, or *senatus*, *ordo*, and *curia*, the states and court of the city. Those magistrates were subordinate to the *prætor* or *proconsul;* but among them there was *one* superior to the rest, called sometimes *dictator* and sometimes *defensor civitatis*, whose jurisdiction extended not only over the city itself, but likewise over all the adjacent territory. That territory was denominated προαστεια, or the suburbs, and often reached to the distance of ten or twelve miles round the city, and sometimes much farther, containing within it many villages and small towns under the government of the city magistrates. From some passages in the New Testament, and from the concurring evidence of the earliest writers of the church, it appears to have been the purpose of the apostles to settle a bishop in every city where there was a civil magistracy; but as they could not be personally present in all places at once, it was natural for them to enter upon the great work of converting the nations by first preaching the gospel in that city of each province which was the ordinary residence of the governor; because to it there must have been the greatest resort of people, who would carry the glad tidings with them into the country when they returned. Accordingly, having dispersed themselves over the empire, and made numbers of proselytes in the principal cities, they fixed in each, where they saw it necessary, a *bishop*, with a college of *presbyters* and *deacons*, and gave to those bishops, who were at first called *apostles*, a commission, as the *other* cities of the province should be converted, to fix bishops in them also.

In some of the smaller cities, it is extremely probable that a bishop and a deacon were for a short time the only ecclesiastical officers, till the number of Christians increased so much as to make it impossible for them all to assemble in one house for the purposes of public worship. The bishop then ordained *presbyters* to officiate in those congregations where he himself could not be present, and to assist him in other parts of his pastoral office; but in all their ministrations the presbyters were subordinate to him, who was the chief pastor within the city, who composed the prayers which were offered up in public, and to whom all the other ministers of religion were accountable for their conduct. As long as the number of the faithful was confined within the *walls* of the city, it appears that the bishop with his presbyters and deacons lived together as in a college; that divine service was every Lord's day, or oftener, performed in what was afterwards called the cathedral or mother-church, by the bishop himself, assisted by some of his clergy; and that the congregations which met in other churches, having no *fixed* pastors, were supplied by such presbyters as the bishop chose to send to them from his own church. Whilst matters continued in this state, the clergy had no other revenues than what arose from the voluntary oblations of the people; which were indeed so large as not only to support them with decency, but likewise to answer other ends of charity and munificence. They were commonly divided into four equal parts; of which one was allotted to the bishop, a second to the inferior clergy, a third to the poor, and a fourth to keep the churches in repair; and it was considered as a part of the bishop's duty to take care that the offerings should be faithfully applied to these purposes.

When converts increased in number, and churches were built in the suburbs, each of these churches had a fixed pastor similar to a parish-priest amongst us; but still those pastors, as well as the city clergy, ministered in subordination to the bishop, whose authority extended as far as the civil authority of the Roman magistrate, within which district or diocese it was supreme over all orders of Christians. This every man knows who is acquainted with ecclesiastical history; for the bishop alone could ordain *priests* and *deacons*, administer the rite of *confirmation*, *absolve penitents* who were under church censure, and *exclude from communion* heretics and notorious offenders; and from his sentence there lay no appeal but to a synod of comprovincial bishops.

Such synods were in each province convened by the bishop of the chief city: for the apostles having been careful to place in those cities men of the most eminent gifts and abilities, the other bishops of the provinces applied to them for advice upon every emergency, and paid a particular deference to them upon every occasion. So that though all bishops were of equal authority *as bishops*, yet when they met to consecrate a new bishop, or to deliberate upon the affairs of the church, they yielded a precedency to the bishop of the metropolis, who called them together, and who sat as *president* or *moderator* of the synod. Hence the origin of metropolitans or *archbishops*, whose authority was so considerable, that though there is not a doubt but the *election* of bishops was anciently placed in the clergy and people of the vacant diocese, yet the bishop *elect* could not be *consecrated* without the consent of the archbishop of the province.

In consequence of the very extensive powers with which the primitive bishops were vested, they are commonly styled in the writings of those times *presidents, provosts*, or *inspectors* of the church, *chief priests, princes of the clergy*, and even *princes of the people;* but their authority was wholly spiritual. Those prelates, imitating the example of their Divine Master when on earth, neither possessed nor assumed to themselves any jurisdiction over the *properties* or *civil rights* of men. In consequence of St Paul's having reprimanded the Corinthians for going to law before the *unbelievers*, they were indeed often chosen as *arbiters* of such civil disputes as arose between individuals under their episcopal government; but on these occasions they could not act unless the submission was *voluntarily* made by *both* the contending parties, and *then* their decision was final. When the empire became Christian, this privilege was confirmed to them by law; for any *civil* cause depending before a court of justice could be withdrawn, and by the mutual consent of parties be submitted to the arbitration of the bishop, whose award, which in former times could be enforced only by the terror of church censures, was then enforced by the secular magistrate. In *criminal* causes, where the trial might be for life or death, they were prohibited, both by the canons of the church and by the laws of the state, from acting as judges; and therefore they never suffered such causes to come before them, excepting when it was necessary that the person accused, if found guilty, should be excluded the communion of the faithful.

Be this as it may, it is certain that, through the liberality of the Christian emperors, the bishops enjoyed large revenues and many valuable privileges; but it does not appear that they had any rank or authority, as *barons* or *temporal princes*, till the Gothic nations, which subverted the Roman empire, had embraced the Christian faith. As Christianity incapacitated the leaders of those tribes from officiating as chief priests at the religious rites which were usually celebrated at the opening of their public assemblies, the bishops came naturally to discharge that duty on such occasions, when they must have shared in the rank by sharing in the functions of the chief. The situation in which they thus appeared at the opening of all political conventions, enabled them to join with much effect in the deliberations which ensued; and their superior knowledge, their sacred character, and their influence with the people, soon acquired them power equal to their rank. They must therefore have been thought entitled to obtain admission into that council which was formed by the king and the lay-chiefs at the national assemblies; and as they balanced the authority of those chiefs, we cannot doubt of the king's disposition to give the utmost effect to their claim. Accordingly, we find the dignified clergy, who received large grants of land to be held on the same tenures with the lands of the lay magistrates, presiding along with those magistrates in the provincial assemblies of every degree in all the Gothic nations, and enjoying every advantage of rank and authority in their national diets. Hence the bishop of Rome, and several bishops in Germany, have, like the dukes and marquises of that empire, been for a long time sovereign princes; and hence too the bishops of England and Ireland have always sat, and have an equal right with the lay-peers to sit, in the upper house of parliament. It is however obvious, that, as far as episcopacy is of *apostolical* institution, those peers and princes possess not the *original* character in any higher degree than the bishops in America, who are merely on a footing of equality with other citizens, or those of Scotland, who are little more than the ministers of a small body of dissenters from an established church.

Having thus traced what we may call the progress of episcopacy from the simple purity of apostolic times up to the gorgeous prelacy of the middle ages, it seems proper, before concluding, that we should briefly allude to the history and present state of episcopacy in Scotland.

About the time of the Reformation, the want of order and decency in the worship of the reformed church was abolished in the reign of James VI. by the establishment of episcopacy on very liberal principles. This mode of worship obtained the sanction of the most respectable part of the nation, and continued to flourish under the auspices of government, till it was overthrown by the adherents to the *national covenant*. Its restoration was, however, effected in the year 1662, and twenty-seven years subsequently it was again abolished by the supporters of the Prince of Orange, afterwards William III.

It may be proper to observe, that the Scotch Episcopal Church had no public liturgy during her legal establishment. It is indeed true that the English book of common prayer was used by the first reformers, and there is reason to believe that John Knox himself was by no means inimical to fixed forms of prayer, nor to clerical subordination; but his successor, Andrew Melvil, introduced an equality among the clergy, and excited the minds of the people against the liturgy to such a degree, that an attempt to modify the prayer-book for the use of the Church of Scotland was productive of the solemn league and covenant, and the subsequent ruin of Charles I.

During the reign of William III. the episcopalians were treated with some degree of severity, because they could not transfer to him that allegiance which they had sworn to King James. It is said that they were prohibited from officiating on the Sabbath-day, except " in their own hired houses, where they received such friends as chose to come in unto them." In this manner was their worship conducted, praying either extempore, or from premeditation, till the accession of Queen Anne, when the English liturgy was introduced by degrees into Scotland, under the sanction of an act of parliament, passed on the third of March 1712, " to prevent the disturbing of those of the episcopal communion in that part of Great Britain called Scotland, in the exercise of their religious worship, and in the use of the liturgy of the Church of England." But as their attachment to the house of Stuart was well known, they were, at the rebellion in 1715, laid under some restraints, yet neither severe in their nature, nor of any long continuance, since in 1720 their places of worship were as numerous as before, and frequented by numbers both of rank and respectability, many of whom held places under government.

In England Dr Sancroft, archbishop of Canterbury, with five other bishops, were deprived of their sees for refusing their allegiance to King William; a circumstance which occasioned a schism in the church, as they were extremely popular. Different opinions were entertained respecting the nature and design of the Lord's Supper, and the controversy infected the Episcopalians of Scotland. On the death of Dr Rose, the proscribed bishop of Edinburgh, the diocesan form of church government was opposed by such of the presbyters as had been raised to the episcopal dignity, and it was proposed to govern the whole church by a college of bishops. This plan, for the adoption of which no precedent could be found in the annals of history, was successfully opposed by many of the most enlightened bishops, and it was of consequence abandoned.

After the rebellion of 1745 additional acts of considerable severity were passed against the Scottish episcopalians, the worst effect of which was the formation of many congregations using the English liturgy, and imagining themselves episcopalians, whilst they and their ministers were living in separation from the bishops of the country. All restraints upon Scottish episcopalians were, however, removed by the act of 1792; since which period they have enjoyed full liberty of conscience, in common with other dissenters from the established church.

The repeal of the penal acts of course tended to unite the independent chapels above mentioned to the episcopal church; but an impediment still existed, which delayed the progress of this union for several years. The Scottish Episcopal Church had never yet adopted the English Confession of Faith; and though the act of 1792 required that every tolerated episcopalian minister should sign the *Thirty-nine Articles*, still, as might have been expected, those ministers were not prepared immediately to sign a declaration of faith at a secular mandate. There consequently remained an ostensible reason for separation till the year 1804, when a convocation of the episcopal church declared their readiness to sign the Thirty-nine Articles of the Church of England, in the manner enacted by the act of 1792.

The cause of separation being thus removed, the English chapels began immediately to unite themselves to the Scottish Episcopal Church, and to submit to the authority of the bishop within whose jurisdiction they lay; and at the present moment (1834) there are but three congregations in Scotland using the English liturgy, who refuse obedience to the Scottish bishops. The episcopal church in Scotland is now governed by six bishops, having under them about seventy presbyters entrusted with the cure of souls.

EPISCOPAL, something belonging to Bishops.

EPISCOPALIANS, in *Ecclesiastical History*, an appellation given to those who prefer the episcopal government and discipline to all others.

EPISCOPIUS, Simon, one of the most learned men of the seventeenth century, and the chief supporter of the Arminian sect, was born at Amsterdam in 1583. In 1612 he was chosen divinity professor at Leyden, in the room of Gomarus, who resigned; but the functions of his office, with his private studies, were light, compared with the difficulties he sustained on account of the Arminian controversy. The states of Holland having invited Episcopius to take his place at the synod of Dort, he went thither, accompanied by some ministers; but the synod would not allow them to sit as judges, nor to appear in any other capacity than as persons summoned before them; and, in the end, they were deposed from their functions and banished. Episcopius and his persecuted brethren retired to Antwerp; but the times growing more favourable, he returned to Holland in 1626, and was made minister of the church of the Remonstrants at Rotterdam. In 1634 he was chosen rector of the college founded by the sect at Amsterdam, and died in 1643. His works form two volumes in folio.

EPISODE, in *Poetry*, a separate incident, story, or action, which a poet invents and connects with his principal action, so that his work may abound with a greater diversity of events. See Poetry.

EPISTEMONARCH, in the ancient Greek church, an officer of great dignity, who, acting in the capacity of censor, had the care of every thing relating to faith.

EPISTLE, the same as letter; but it is now chiefly used in speaking of ancient writings, as the epistles of St Paul, of Cicero, of Pliny, and so on.

Epistles and Gospels, in the liturgy of the Church of England, are portions of Scripture selected from the writings of the evangelists and apostles, and appointed to be read, in the communion service, on Sundays and holidays. They are believed to have been selected by St Jerome, and by him put into the lectionary.

The epistles and gospels are placed in an admirable order and method, and bear a special relation to the several days on which they are read. The year is distinguished into two parts; the first being designed to commemorate Christ's sojourn upon earth, and the other to instruct us to live after his example. The former includes the whole time from Advent to Trinity Sunday; the latter all the Sundays from Trinity to Advent.

EPISTYLE, in the ancient architecture, a term used by the Greeks for what we call *architrave*, that is, a massive piece of stone or wood laid immediately over the capital of a column.

EPITAPH (from επι, *upon*, and ταφος, *sepulchre*), a monumental inscription in honour or in memory of a person deceased. It has been disputed whether the ancient Jews inscribed epitaphs on the monuments of the dead; but however this may be, it is certain that epitaphs of very ancient date are found among them. The Athenians, by way of epitaph, commonly put only the name of the dead, with the epithet χρηστος, signifying *good*, or ἡρως, *hero*, and the word χαιρε, intimating their good wishes; but the name of the deceased's father and that of his tribe were occasionally added. The Lacedæmonians allowed epitaphs to none but those who had died in battle. The Romans inscribed their epitaphs *diis manibus;* and frequently introduced the dead, by way of prosopopœia, speaking to the living.

EPITHALAMIUM, in *Poetry*, a nuptial song or composition in praise of the bride and bridegroom, and praying for their prosperity.

Epithalamia were sung amongst the Jews at the door of the bride, by her friends and companions, the evening before the marriage. Amongst the Greeks the epithalamium was sung as soon as the married couple had gone to bed, and was attended with shouts and stamping of the feet to drown the cries of the bride. They returned in the morning, and with the same song, a little altered, saluted them again. The evening song was called επιθαλαμια κοιμητικα, the morning salute was called επιθαλαμια εγερτικα. The practice amongst the Romans was the same, but their epithalamia were often obscene.

EPITHET, in *Poetry* and *Rhetoric*, an adjective expressing some quality of a substantive to which it is joined, or such an adjective as is annexed to substantives by way of ornament and illustration, not to make up an essential part of the description.

EPITOME, in literary history, the same with ABRIDGMENT.

EPITRITUS, in *Prosody*, a foot consisting of three long syllables and one short. Of these, grammarians reckon four kinds; the first consisting of an iambus and spondee, as *sălūtāntēs;* the second, of a trocheus and spondee, as *cōncĭtātī;* the third of a spondee and an iambus, as *cōmmūnĭcāns;* and the fourth of a spondee and trocheus, as *īncāntārĕ*. See the articles SPONDEUS, TROCHEUS, and IAMBUS.

EPITROPUS, a kind of judge, or rather an arbitrator, which the Greek Christians, under the dominion of the Turks, were in use to elect in the several cities, in order to terminate the differences that arose among them, and thus avoid carrying them before the Turkish magistrates. See ARBITRATOR.

EPOCHA, in *Chronology*, a term or fixed point of time whence the succeeding years are numbered or reckoned.

EPODE, in *Lyric Poetry*, the third or last part of the ode, the ancient ode being divided into strophe, antistrophe, and epode. The epode was sung by the priests, standing still before the altar, after all the turns and returns of the strophe and antistrophe, and was not confined to any precise number or kind of verses. The epode is now a general name for all kinds of little verses which follow one or more great ones, of what kind soever these be; and in this sense a pentameter is an epode after an hexameter.

EPOPŒIA, in *Poetry*, the history, action, or fable, which forms the subject of an epic poem. The word is derived from the Greek επος, *carmen*, verse, and ποιεω, *facio*, I make. In the common use of the word, however, *epopœia* is the same with *epos*, or epic poem itself. See POETRY.

EPPING, a market-town of the county of Essex, in the hundred of Waltham, seventeen miles from London. It was remarkable for its situation in a district formerly very woody, and preserved by our ancient monarchs for the enjoyment of the sports of the field. It was then called Waltham Forest, and extended almost to the capital. In the same neighbourhood also was Hainault Forest, where a fair was held for many centuries under a remarkable tree, well known by the name of Fairlop Oak, which has existed till recently, and was of prodigious size. The greater part of these districts have been disforested, and converted into fertile fields. The town of Epping has a market, which is held on Friday, but at a small distance from the buildings. It preserves the fame it has long enjoyed for its butter, its sausages, and its pork, in the London markets. The population amounted in 1801 to 1729, in 1811 to 1874, in 1821 to 2146, and in 1831 to 2313.

EPPINGEN, a city, the capital of a bailiwick of the same name, in the grand duchy of Baden in Germany. It is situated on the river Elsenz, and contains 336 houses, with 2439 inhabitants.

EPSOM, a town of the county of Surrey, fifteen miles from London. It was formerly frequented on account of its saline springs, and is now so on account of the races held on the down near it. County meetings are generally held here. The neighbourhood abounds with elegant seats of the nobility and gentry. The population amounted in 1801 to 2404, in 1811 to 2515, in 1821 to 2890, and in 1831 to 3231.

EPULARES, in *Antiquity*, an epithet given to those who were admitted to the sacred *epulæ* or entertainments, it being unlawful for any to be present at them who were not pure and chaste.

EPULO, in *Antiquity*, the name of a minister of sacrifice among the Romans.

The pontifices not being able to attend all the sacrifices performed at Rome to the numerous gods adored by that people, appointed three ministers, whom they called *epulones*, because they had conferred on them the care and management of the *epula*, or feasts in the solemn games and festivals. Their number was at length augmented from three to seven, and afterwards to ten. Their first establishment was in the year of Rome 558, under the consulate of L. Furius Purpureo and M. Claudius Marcellus.

EPULUM, in *Antiquity*, a solemn feast prepared for the gods in times of public danger. The feast was sumptuous, and the gods being formally invited, attended by proxy; for the statues were brought on rich beds furnished with soft pillows, called *pulvinaria;* and thus accommodated, their godships were placed on their couches at the most honourable part of the table. The care of the *epula* belonged to the *epulones*, and the gods were plentifully served with the richest dainties, as if they were able to eat; but the *epulones* performed that function for the divinities, and no doubt showed themselves competent proxies.

EPULUM is also used to signify any solemn feast; and hence we meet with *epulum ferale*, a funeral entertainment.

EQUABLE, an appellation given to such motions as always continue the same, without being either accelerated or retarded.

EQUAL, a term of relation between two or more things of the same magnitude, quantity, or quality. Mathematicians speak of *equal* lines, angles, figures, circles, ratios, solids.

EQUALITY is that agreement between two or more things, by which they are denominated equal.

EQUANIMITY denotes that calm and even frame of mind and temper, under good or bad fortune, by which a man appears to be neither puffed up nor overjoyed with prosperity, nor dispirited, soured, or rendered uneasy by adversity.

EQUATIONS.

1. In all the applications of algebra, it is not the magnitudes concerned that we immediately consider, but merely their proportions. In every class of quantities of the same kind, one being adopted as the unit of comparison, all the rest are referred to this standard, and are represented by the proportions they bear to it. The letters of the alphabet, or other symbols, used in algebra, are not, therefore, properly speaking, the representatives of magnitudes; they denote ratios, or abstract numbers, viewed, as in the fifth book of Euclid, in the most general manner, and independently of any particular system of arithmetic or numeration.

The ancient geometry follows a different procedure. In that science the attention is in every case confined to the magnitudes under actual consideration. A general property of triangles is established, by showing that it is true of any particular triangle that comes under the proposed hypothesis. The geometer contemplates particular instances, presenting for the most part relations not very complex, and easily kept in view. On this account he carries on his investigations with the greatest clearness, and is in no danger of falling into contradiction or paradox. But his science is little susceptible of general methods. If any process within the compass of the ancient geometry be entitled to that appellation, it is what is called the method of exhaustion. Every geometer perceives that all the demonstrations under this head have the closest analogy. Yet, after a hundred applications, it is still necessary, in any new case, to pursue the reasoning through all its details, without deriving assistance from any general conclusion previously obtained.

Algebra possesses a great advantage over geometry in generalizing its processes. Problems relating to magnitudes of the most different kinds, nevertheless, lead to similar expressions in numbers. Questions in geometry, in mechanics, or concerning mercantile business, are made to depend on the same rules for their solution. It may be said that algebra and the modern analysis accomplish, for all the mathematical sciences, the project, entertained by some ingenious men, of an universal and philosophical language, which, being founded on an exact scrutiny into the nature of things, and on what they possess in common, might greatly facilitate the acquisition and the extension of our knowledge.

The spirit of generalization peculiar to algebra is nowhere more conspicuous than in the doctrine of equations. Every determinate problem that can occupy the attention of the mathematician, is ultimately reduced to the finding of such numbers as are necessary to determine the unknown quantity or quantities, by means of the equations that subsist between those numbers, and others which are given in the question. A wide field of mathematical investigation is thus brought under a limited number of algebraic expressions.

In treating of equations, it will not be necessary to begin with laying down a formal definition. We confine ourselves, in this article, to the consideration of such equations as contain only one unknown quantity. We further suppose that the elementary operations preparatory to solution are already performed; so that the unknown quantity is clear of radical signs, and is nowhere found in the denominator of a fraction; likewise that all the separate terms are brought to one side of the sign of equality, and arranged in such a manner that the first term, which must always be positive, and have unit for its index, contains the highest power of the unknown quantity, or x; the second term contains the next highest power, and so on, the term which does not contain x being placed last. This arrangement must always be understood when any term is distinguished by the order it stands in; but it will sometimes be convenient to write the terms in an inverted order, arranging them according to the indices of the unknown quantity.

Equations are divided into different classes or orders, according to the highest power of the unknown quantity found in their terms.

An equation of the first degree, or a simple equation, is one which contains x only, without any of its powers, as $x - \mathrm{A} = 0$.

A quadratic equation, or one of the second degree, contains the square of x, as $x^2 - \mathrm{A} = 0$, or $x^2 - \mathrm{A}x + \mathrm{B} = 0$.

A cubic equation, or one of the third degree, contains the cube, or third power of x, as $x^3 - \mathrm{A} = 0$, or $x^3 - \mathrm{A}x^2 + \mathrm{B}x - \mathrm{C} = 0$.

A biquadratic equation, or one of the fourth degree, contains the fourth power, or biquadrate of x, as $x^4 - \mathrm{A} = 0$, or $x^4 - \mathrm{A}x^3 + \mathrm{B}x^2 - \mathrm{C}x + \mathrm{D} = 0$.

And, in general, an equation of the n^{th} degree contains the n^{th} power of x, and the powers inferior to the n^{th}, such as

$$x^n - \mathrm{A}x^{n-1} + \mathrm{B}x^{n-2} \ldots\ldots\ldots\ldots - \mathrm{M}x + \mathrm{N} = 0.$$

A root of an equation is a value of the unknown number x. Thus, if a represent a number, and if its powers, a, a^2, a^3, when they are substituted in the equation for x, x^2, x^3, &c. produce an equality between the positive and negative terms, then a is a root of the equation, and it is a positive root; but if, for x, x^2, x^3, &c. we must substitute $-a$, a^2, $-a^3$, &c. which are the powers of $-a$, in order to obtain the like equality, then a is a negative root of the equation.

What we have here called roots are more generally named *real roots*, to distinguish them from those expressions to which the appellation of *imaginary or impossible roots* has been given. As it will conduce to perspicuity, we shall always use the word root in the sense here defined, unless when imaginary or impossible roots are expressly mentioned.

From the definitions laid down, it follows that the negative roots of the equation,

$$0 = \mathrm{N} + \mathrm{M}x + \mathrm{L}x^2 + \mathrm{K}x^3 +, \&c.$$

are the same with the positive roots of the equation,

$$0 = \mathrm{N} - \mathrm{M}x + \mathrm{L}x^2 - \mathrm{K}x^3 +, \&c.$$

in which the signs only of all the terms containing the odd powers of x are changed. For the same result is obtained, whether we make x equal to $-a$ in the first equation, or to $+a$ in the second.

2. A great advantage has resulted from the practice introduced by Harriot, of writing all the terms of an equation on one side of the sign of equality. The polynomes formed by all the terms thus brought together are rational and integral functions of the unknown quantity; and the question is, to find in what circumstances such expressions are equal to zero. The most likely way of succeeding in this research, is to resolve the functions into their most simple component factors. Harriot supposed that every rational function can be produced by the continued multiplication of binomial factors, and in

this he has been followed by succeeding algebraists. The modern theory of equations is entirely founded on this supposition, which, although it has not been demonstrated, has yet, in some measure, been verified in the progress of the science, and by the admission of those artificial expressions called imaginary or impossible quantities. But there is a distinction between the real and impossible binomial factors of a rational polynome; for the first are expressions complete and significant by themselves, without reference to other quantities; whereas one impossible factor necessarily supposes the existence of another, the two related expressions being such that their multiplication produces one real factor of the second degree. Thus, every pair of impossible factors is equivalent to a real quadratic factor; and, by an unavoidable consequence of the forced supposition made by Harriot, the attention of algebraists has been drawn to the two impossible expressions, instead of the real one which they compose. In order to place the doctrine of equations and the theory of impossible roots on a solid foundation, it appears necessary to attempt the resolution of rational functions into their component factors by a rigorous analysis, free from arbitrary suppositions.

To resolve the rational function $f(x)$ into its component factors, we must begin with inquiring whether it can be divided without a remainder, by a division such as $x-a$, or $x+a$. If it can, the proposed function will be equal to $(x \mp a) \times f'(x)$, where $f'(x)$, the quotient of the division, is a function similar to $f(x)$, but of an order one degree lower. In like manner, it may be possible to reduce $f'(x)$ to a degree still lower, by means of one or more divisors of the same form; and, in certain cases, the first function may be entirely exhausted by successive binomial divisors. When this happens, the divisors $x-a$, $x-b$, $x-c$, &c. will be equal in number to the exponent of the highest power of x, and their continued product will be equal to $f(x)$. It is evident, that by multiplying together a proper number of such factors, an algebraic expression may be formed similar to any rational and integral function, and the co-efficients of this product will likewise contain as many quantities to be determined at pleasure as there are co-efficients in the given function. But we should reason badly if, from this process of composition, we should infer that a product arising from the multiplication of a certain number of simple factors may have any given co-efficients, or will coincide with any proposed polynome of the same degree. This is a point that can be ascertained only by a process of analysis or resolution, and by seeking all the binomial divisors any given function admits of. In fact, the cases are extremely rare in which an algebraic function can be completely exhausted by real binomial divisors. There are many polynomes which have not a single divisor of this kind; and, in the progress of resolution, we generally arrive at a function which cannot be further divided. When this is the case, it must be tried whether a quadratic divisor, as x^2+mx+n, will not be successful in lowering the function. But here it must be observed that such divisors are of two kinds; one, as $(x-\varrho)^2-\tau^2$, which can be resolved into two binomial factors; and one, as $(x-\varrho)^2+\tau^2$, which cannot be so resolved without introducing imaginary or impossible expressions. Now, to divide by a divisor of the first kind is the same thing as to divide by the two binomial factors of which it is composed; and, therefore, it is the second kind of quadratic factors only that need be tried, or that can succeed, in lowering a function already deprived of all its simple divisors. After quadratic divisors, those of the third degree would naturally come to be considered; but this is unnecessary, because algebraists have found that every rational function may be completely exhausted by simple and quadratic factors.

What has now been said naturally distributes the subject under two heads; one treating of the simple or binomial factors, and the other of the quadratic or trinomial factors, of algebraic equations.

Binomial Factors.

3. The first object of inquiry must be to find the conditions necessary, in order that a binomial quantity, as $x-a$, or $x+a$, shall divide a rational polynome without a remainder. Suppose that $x-a$ is a divisor of the polynome,

$$x^n + Ax^{n-1} + Bx^{n-2} \ldots\ldots\ldots\ldots + Mx + N,$$

which we shall denote by $f(x)$: then we shall have

$$f(x) = N + Mx + Lx^2 + Kx^3 +, \&c.$$
$$f(a) = N + Ma + La^2 + Ka^3 +, \&c.$$

wherefore, by subtracting and dividing by $x-a$, we get

$$\frac{f(x)}{x-a} - \frac{f(a)}{x-a} = M\frac{x-a}{x-a} + L\frac{x^2-a^2}{x-a} + K\frac{x^3-a^3}{x-a} +, \&c.$$

Now, it is known that the difference between any like powers of two numbers is exactly divisible by the difference of those numbers: hence all the quantities on the right-hand side of the sign of equality form an integral expression. But as $f(a)$ does not contain x, it cannot be divisible by $x-a$; it follows, therefore, that $f(x)$ cannot be divisible by $x-a$, unless $f(a)=0$; and it is obvious that this condition is the only one necessary. Thus, the polynome $f(x)$ will be divisible by $x-a$ when a is a positive root of the equation $f(x)=0$, otherwise not.

Again, let the divisor be $x+a$; then,

$$f(x) = N + Mx + Lx^2 + Kx^3 +, \&c.$$
$$f(-a) = N - Ma + La^2 - Ka^3 +, \&c.$$

and by proceeding as before,

$$\frac{f(x)}{x+a} - \frac{f(-a)}{x+a} = M \cdot \frac{x+a}{x+a} + L\frac{x^2-a^2}{x+a} + K \cdot \frac{x^3+a^3}{x+a} +, \&c.$$

Here again all the divisions on the right-hand side of the sign of equality can be exactly performed; and we must, therefore, conclude that $f(x)$ will be divisible by $x+a$ only when $f(-a)=0$, that is, when a is a negative root of the equation $f(x)=0$.

Now $x \mp a$ being a divisor of $f(x)$, the quotient, which we may denote by $f'(x)$, will be a polynome of $(n-1)$ dimensions, or one degree lower than $f(x)$; and we shall have

$$f(x) = (x \mp a) \times f'(x).$$

From this equation it appears that every value of x that makes $f'(x)$ equal to zero, will likewise make $f(x)$ equal to zero; consequently every binomial divisor of the first function will likewise be a divisor of the second. And if $f'(x)$ has no roots, and no binomial divisors, neither will $f(x)$ have any roots except $\pm a$, nor any binomial divisors except $x \mp a$. Suppose that the polynomes $f(x)$ and $f'(x)$ have the common root $\pm b$; they will likewise have the common divisor $x \mp b$; and if we put $f''(x)$ for the quotient arising from the division of $f'(x)$ by $x \mp b$, so that $f'(x) = (x \mp b) \cdot f''(x)$, we shall have

$$f(x) = (x \mp a) \cdot (x \mp b) \cdot f''(x),$$

in which equation $f''(x)$ is a polynome of $n-2$ dimensions, or two degrees lower than $f(x)$.

It is evident we may continue to reason in the same manner either till, after successive divisions, we come at last to a binomial quotient, in which case the original polynome $f(x)$ will be completely resolved into binomial factors; or till we come to a quotient that has no roots, in which case $f(x)$ will have no binomial factors except those previously found. We may therefore conclude that "a rational polynome has as many binomial factors as it has roots, and no more; every positive root producing a factor of the form $x-a$, and every negative root one of the form $x+a$; and since the number of binomial factors can never be greater than the dimensions of the polynome, its roots cannot exceed the same number."

4. There are very few cases in which it can be known immediately and by inspection that an equation has one or more roots. These cases depend upon the following propositions, viz. "If $\varphi(x)$ denote a rational polynome, having x, or some integral power of x, in every one of its terms, and likewise having the term that contains the greatest power of x positive, a value of x may be found that will make $\varphi(x)$ equal to any positive quantity, as s."

Suppose, first, that all the terms of $\varphi(x)$ are positive; then x^n being the first term, or that in which x rises to the highest power, if $s=t^n$, and $\lambda > t$, it is manifest that

$$\varphi(\lambda) > t^n > s.$$

Therefore, while x increases from 0 to be equal to λ, the function $\varphi(x)$ increases from 0 to be greater than s; and as the variations of $\varphi(x)$, however irregular they may be, are connected by the law of continuity, the function will pass through every gradation of magnitude between 0 and the greatest limit $\varphi(\lambda)$. Consequently, there is a value of x between 0 and λ, that will make $\varphi(x)$ equal to s.

When the terms of $\varphi(x)$ are not all positive, let all the positive terms except x^n be rejected, and all the negative terms be retained, and we shall have $\varphi(x)$ equal to, or greater than,

$$x^n - Fx^{n-i-1} - Hx^{n-i'-1} -, \&c.$$

But, s being equal to t^n, we have

$$t^n = x^n - (x-t) . \left\{ x^{n-1} + tx^{n-2} + t^2 x^{n-3} \ldots + t^{n-1} \right\}$$

Now, by equating the negative terms of the first expression to the terms containing the like powers of x in the value of t^n, we shall get

$$(x-t) . t^i = F, \quad (x-t) . t^{i'} = H, \&c.$$

And hence,

$$x = t + \frac{F}{t^i}, \quad x = t + \frac{H}{t^{i'}}, \&c.$$

Let λ be either equal to or exceed the greatest of those values of x, then we shall have

$$\varphi(\lambda) > t^n > s.$$

Wherefore, as before, there is a value of x between 0 and λ, that will make $\varphi(x)$ equal to s.

From what has now been proved, we derive the following properties of equations.

1. "Every equation of odd dimensions has at least one positive root when the last term is negative, and one negative root when the last term is positive."

If the last term be negative, as in this instance,

$$x^{2n+1} + Ax^{2n} + Bx^{2n-1} \ldots + Mx - N = 0;$$

according to what has been proved, a value of x, viz. a, may be found that will satisfy the condition,

$$a^{2n+1} + Aa^{2n} + Ba^{2n-1} \ldots + Ma = N;$$

then a is a positive root of the equation.

When the last term is positive, as in this equation,

$$x^{2n+1} + Ax^{2n} + Bx^{2n-1} \ldots + Mx + N = 0,$$

change the sign of the last term, and the signs of all the terms that contain the even powers of x, then the polynome will become

$$x^{2n+1} - Ax^{2n} + Bx^{2n-1} \ldots + Mx - N:$$

and a value of x, viz. a, may be found such that

$$a^{2n+1} - Aa^{2n} + Ba^{2n-1} \ldots + Ma = N.$$

Now transpose N, and then change the signs of all the terms, and we shall get

$$-a^{2n+1} + Aa^{2n} - Ba^{2n-1} \ldots - Ma + N = 0,$$

which shows that a is a negative root of the equation.

2. "Every equation of even dimensions having its last term negative, has two roots, one positive and one negative."

Let the equation be

$$x^{2n} + Ax^{2n-1} + Bx^{2n-2} \ldots + Mx - N = 0;$$

and consider the polynomes,

$$x^{2n} + Ax^{2n-1} + Bx^{2n-2} \ldots + Mx - N,$$
$$x^{2n} - Ax^{2n-1} + Bx^{2n-2} \ldots - Mx - N,$$

in the latter of which the signs of all the terms containing the odd powers of x are changed; then there are two values of x, viz. a and b, such as to answer the conditions,

$$a^{2n} + Aa^{2n-1} \ldots + Ma = N$$
$$b^{2n} - Ab^{2n-1} \ldots - Mb = N:$$

consequently a is a positive and b a negative root of the equation.

3. "A polynome of even dimensions, which has no binomial factors, is always positive, whatever value be substituted for the unknown quantity."

Let the polynome be $f(x)$ or

$$x^{2n} + Ax^{2n-1} \ldots Mx + N;$$

then the last term, or that term which does not contain x, must be positive; for otherwise the polynome would have two roots and two binomial factors, contrary to the hypothesis. Now, if it be possible, let the polynome have a negative value when λ is substituted for x, so that $f(\lambda) = -P$; therefore, when $x=0$, $f(x)$ is equal to the positive quantity N; and, when $x=\lambda$, the same function is equal to $-P$; but since $f(x)$ passes through all degrees of magnitude between N and $-P$, while x varies from 0 to λ, it will become equal to zero when x has some intermediate value; therefore the polynome has one root between 0 and λ, and one binomial divisor corresponding to that root, contrary to the hypothesis.

It may be observed, that the converse of this proposition is not true; for a polynome of even dimensions, that has such factors as $(x-a)^2$, $(x-a)^4$, $(x-a)^{2m}$, may never become negative, although it is capable of being equal to zero.

5. The properties demonstrated in the last section lead to this general proposition relating to the number of roots in any equation, viz. "In any equation the number of all the roots is even when the dimensions are even, and odd when the dimensions are odd."

For every equation has as many binomial divisors as it has roots; and if we suppose an odd number of roots in an equation of even dimensions, or an even number in one of odd dimensions, the last quotient, after dividing successively by all the divisors, would be a polynome of odd dimensions, having at least one root, which would likewise be a root of the proposed equation. Therefore the number of all the roots of an equation cannot be even when the dimensions are odd, nor odd when the dimensions are even.

And again, since every polynome is equal to the continued product of all its binomial divisors, and the quotient last found, after dividing by them all successively, we obtain the following proposition, viz.: "Every rational polynome is equal either to the continued product of as many binomial factors as it has dimensions; or to the continued product of an even or odd number of such factors, according as the dimensions of the polynome are even or odd, and a polynome of even dimensions, which, having no binomial factors, is always positive, whatever value be substituted for the unknown quantity."

Equal roots.

6. When several of the binomial factors of an equation are equal to one another, it is said to have so many equal roots. In this case the equation can be divided a number of times successively by the same binomial divisor. Thus, an equation which is twice divisible by $x-a$, or, which is the same thing, once by $(x-a)^2$, has two roots equal to a; and if it can be divided by $(x-a)^m$, it has m roots equal to a.

The most obvious way of finding the conditions on which the equality of the roots depends would therefore be to expand the divisor $(x-a)^m$ by the binomial theorem, and then divide the equation by it; for, after the integral quotient is obtained, the required conditions will be found by making the several parts of the remainder separately equal to zero. The number of the conditions found in this manner is equal to the exponent of the divisor; for of so many parts will the remainder of the division consist. But, in a complex operation, it is difficult to ascertain the remainder; and, besides, it is not necessary to consider all the equations obtained by this process, because both the number and the value of the equal roots can be found by means of two of them only.

The inconveniences just mentioned will be avoided by proceeding in the following manner: Let the equation be

$$x^n+Ax^{n-1}+Bx^{n-2}\ldots+Mx+N=0;$$

then, if it be divisible by $(x-a)^m$, the quotient will be a polynome of $n-m$ dimensions; and we may therefore suppose that the expression

$$x^n+Ax^{n-1}+Bx^{n-2}\ldots+Mx+N$$

is equal to the product,

$$(x-a)^m\times\{x^{n-m}+A'x^{n-m-1}+B'x^{n-m-2}+,\text{ \&c.}\}.$$

In these expressions, x may have any value whatever; and therefore the equality between them will still subsist if we substitute $x+i$ for x, i being any arbitrary number; therefore the expression

$$(x+i)^n+A(x+i)^{n-1}+B(x+i)^{n-2}\ldots+M(x+i)+N$$

will be equal to the product

$$(x-a+i)^m\times\{(x+i)^{n-m}+A'(x+i)^{n-m-1}+,\text{ \&c.}\}.$$

Now, let the several powers of $(x+i)$ be expanded by the binomial theorem, and put

$$X=x^n+Ax^{n-1}+Bx^{n-2}\ldots+Mx+N,$$

$$Y=nx^{n-1}+(n-1)Ax^{n-2}+(n-2)Bx^{n-3}\ldots+M,$$

$$Z=n\frac{n-1}{2}x^{n-2}+(n-1)\frac{n-2}{2}Ax^{n-3}+,\text{ \&c.}$$

$$V=n\frac{n-1}{2}\cdot\frac{n-2}{3}x^{n-3}+(n-1)\cdot\frac{n-2}{2}\cdot\frac{n-2}{3}Ax^{n-4}$$

$$+,\text{ \&c.}\qquad\text{\&c.}\qquad\text{\&c.}$$

then the given polynome of n dimensions will become

$$X+Yi+Zi^2+Vi^3+,\text{ \&c.}\qquad\text{(A).}$$

And if the like operations are performed in the polynome of $n-m$ dimensions, and $(x-a+i)^m$ be expanded by the binomial theorem, the product of these two expressions will become

$$\left\{(x-a)^m+m.(x-a)^{m-1}i+m.\frac{m-1}{2}.(x-a)^{m-2}i^2\right.$$

$$\left.+,\text{ \&c.}\right\}\times\left\{X'+Y'i+Z\,i^2+,\text{ \&c.}\right\}.\qquad\text{(B).}$$

The expression (A) being equal to the product (B), whatever i stands for, the co-efficients of the like powers of i must be equal; and hence, by equating the terms in which i is wanting, and likewise the terms that contain the first power of i, we get

$$X=(x-a)^mX'$$

$$Y=(x-a)^mY'+m(x-a)^{m-1}X';$$

which proves that $(x-a)^{m-1}$ is a common divisor of X and Y. If, therefore, by means of the usual process, we seek the greatest common measure of the two polynomes X, Y, or,

$$x^n+Ax^{n-1}+Bx^{n-2}\ldots\ldots+Mx+N,$$

$$nx^{n-1}+(n-1)Ax^{n-2}+(n-2)Bx^{n-2}\ldots+M;$$

we shall obtain the factor $(x-a)^{m-1}$, and the given polynome X will be divisible by $(x-a)^m$; that is, it will contain the common factor $x-a$ once more than the polynome Y contains it.

If we proceed farther, and equate the co-efficients of i^2 in the expressions (A) and (B), we shall get

$$Z=(x-a)^mZ'+m(x-a)^{m-1}Y'$$

$$+m.\frac{m-1}{2}(x-a)^{m-2}X';$$

which shows that Z is divisible by $(x-a)^{m-2}$. In the same manner, it may be proved, that V is divisible by $(x-a)^{m-3}$, and so on. It appears, therefore, that the first m co-efficients of the expression (A) are respectively divisible by $(x-a)^m$, $(x-a)^{m-1}$, $(x-a)^{m-2}$, &c.; and consequently we shall have

$$X=0,\ Y=0,\ Z=0,\ V=0,\text{ \&c.}$$

when the common root a is substituted for x.

If the polynome X is divisible by $\{(x-\alpha^2+\beta^2)\}^n$, it may be proved in like manner that $\{(x-a)^2+\beta^2\}^{n-1}$ will be a common divisor of X and Y.

We may therefore lay down the following rule for finding all the double, triple, &c. divisors of any given polynome X: "Find R, the greatest common measure of X and Y, and resolve it into its elementary factors; then each of these factors will be contained in X once more than in R."

7. If it be required to find how many of the roots of an equation are positive, and how many are negative, we have for this purpose the rule first published in the *Geometry* of Descartes. This celebrated rule seems to have been discovered by induction; at least its author gave no demonstration of it, and disputes arose about its true import. It was demonstrated for the first time by Du Gua, in the *Mémoires de Paris*; but many other demonstrations of it have since appeared, of which that of Segner, in the *Mémoires de Berlin*, 1756, is not only the most simple, but probably the most simple that will ever be invented.

Segner deduced the rule of Descartes from the following analytical proposition, viz.

"If any rational polynome be multiplied by $x-a$, the changes from one sign to another, from + to — 1, and from — to + 1, will be at least one more in the product than in the given polynome; and if it be multiplied by $x+a$, the successions of the same sign, of + to + 1, and of — to — 1, will be at least one more."

Let the proposed polynome be

$$x^n\pm Ax^{n-1}\pm Bx^{n-1}\ldots\ldots\pm Mx\pm N;$$

then, according to the usual process, the product of the polynome by $x-a$ will be found by adding these two lines, viz.

$$\left.\begin{array}{l}x^{n+1}\pm Ax^n\pm Bx^{n-1}\ldots\pm Mx^2\pm Nx\\ \qquad -ax^n\mp Aa^{xn-1}\ldots\quad\mp Lax^2\mp Max\mp Na\end{array}\right\}$$

the signs of the several terms remaining unchanged in the first line, and being all changed in the second line. It is evident, therefore, that the terms of the product will have the same signs with the respective terms of the proposed polynome, except when a co-efficient in the second line is greater than the one above it, and likewise has a contrary sign; the sign of the last term of the product being always the same with the sign of the last term of the second line. Now, beginning on the left hand, pass over the terms of the first line, so long as they have the same signs with the terms of the product. When this ceases to be the case, the signs in the product will be the same as in the second line, and contrary to those in the first line; wherefore descend to the second line, and pass along its terms till the signs in the product are again the same as those in the first line, and then ascend to that line. Continue thus descending and ascending alternately till all the terms in both lines are taken in. At the conclusion, it is evident that the descendings are always one more than the ascendings, because the passing from one line to another both begins and ends with descending.

If we descend from $\pm Ax^n$ in the first line, to $\mp Aax^{n-1}$ in the second line, it is evident that the signs of $\pm Ax^n$ and $\pm Bx^{n-}$ in the first line will be the same, both being contrary to the sign of $\mp Aax^{n-1}$ in the second line. Therefore, in the given polynome, the first and second terms have the same sign. But in the product the like terms have contrary signs; for the second term of the product has the same sign with $\pm Ax^n$ in the first line, and the third term of the product has the same sign with $\mp Aax^{n-1}$ in the second line. Thus it appears that a variation from one sign to another is introduced in the product, instead of a continuation of the same sign that takes place in the given polynome; and the same thing will happen at every descending.

In ascending from the second line to the first, there may either be a continuation of the product instead of a variation in the given polynome, or the contrary; but one of these two must take place.

Now, so long as we keep on the first line, the signs in the product are the same with those of the given polynome; and, so long as we keep on the second line, the signs in the product are contrary to those in the polynome. In both cases, therefore, the variations from + to — 1, and from — to + 1, are the same in the product and in the polynome. Every descending introduces a variation in the product, instead of a continuation that takes place in the polynome; and although it be supposed that every ascending introduces a continuation in the product instead of a variation that exists in the polynome, yet, on the whole, the variations introduced must be one more than the continuations, because the descendings are one more than the ascendings.

Again, if the given polynome be multiplied by $x + a$, the product will be the sum of these two lines, viz.

$$\left.\begin{array}{l} x^{n+1} \pm Ax^n \pm Bx^{n-1} \ldots \pm Mx^2 \pm Nx \\ \qquad + ax^n \pm Aax^{n-1} \qquad \pm Lax^2 \pm Max \pm Na. \end{array}\right\}$$

Here the terms of both lines have the same signs; and, as before, the signs in the product will be the same with the signs of the proposed polynome, unless when a co-efficient in the second line is greater than the one above it, and likewise has a contrary sign; the sign of the last term of the product being always the same with the sign of the last term in the second line. Now, if we pass along all the terms of both lines, descending from the first line to the second, when the signs in the product change from being the same with those in the given polynome, to be contrary to them; and ascending from the second line to the first, when the signs in the product change from being contrary to those in the polynome, to be the same with them; it is evident that the descendings will be one more than the ascendings, as in the former case.

If we descend from $\pm Ax^n$ in the first line, to $\pm Aax^{n-1}$ in the second line, the two terms $\pm Ax^n$ and $\pm Bx^{n-1}$ in the first line will have different signs; for, on account of the descending, $\pm Bx^{n-1}$ has a contrary sign to the term $\pm Aax^{n-1}$ below it, and, consequently, to $\pm Ax^n$ in the first line. Therefore the second and third terms in the polynome have different signs. But the like terms in the product have the same sign; for the second term in the product has the same sign with $\pm Ax^n$ in the first line; and the third term of the product has the same sign with $\pm Aax^{n-1}$ in the second line. Thus there is a continuation of the same sign introduced in the product, instead of a variation from one sign to another that takes place in the polynome; and the same thing is true at every descending.

In ascending from the second line to the first, there may either be a variation in the product instead of a continuation that exists in the polynome, or the contrary. But one of these two must take place.

Now it is evident that, except at the descendings and ascendings, there is the same number of continuations of the same sign, and the same number of variations from one sign to another, in the product and in the given polynome. Every descending introduces a continuation in the product instead of a variation existing in the polynome. And even if we suppose that every ascending introduces a variation in the product instead of a continuation that takes place in the polynome, yet, on the whole, there will be one continuation more in the product than in the polynome, because the descendings are one more than the ascendings.

In the preceding demonstration, it is supposed that all the ascendings have a contrary effect to the descendings, by which means there is introduced in the product the least possible number of variations from one sign to another in the one case, and the least possible number of continuations of the same sign in the other. But if, in the first case, we suppose that, at one ascending, there is a variation in the product, and a continuation in the polynome, this will add one to the variations in the product, and one to the continuations in the polynome; so that the variations in the product will now exceed those in the polynome by three, namely, by two more than in the circumstances supposed in the demonstration. And if we extend the like reasoning to two, three, &c. ascendings, the variations in the product will exceed those in the polynome respectively by five, seven, &c. The like conclusion is evidently true of the second case, *mutatis mutandis;* and hence the preceding proposition, when it is generalized as much as it can be, may be thus enunciated: "If any rational polynome be multiplied by $x - a$, the variations from one sign to another in the product will exceed those in the polynome by one, or three, or five, or by some odd number; and if it be multiplied by $x + a$, the continuations of the same sign in the product will exceed those in the polynome by one, or three, or five, or by some odd number."

Now, if we conceive that any rational polynome is resolved into its binomial factors, there will be a factor of the form $x - a$ for every positive root, and one of the form $x + a$ for every negative root; and when all the factors are multiplied together in order to reproduce the polynome, it follows, from what has been proved, that the product will contain at least one change from + to —, or from — to + 1, for every factor of the form $x - a$, or for every positive root; and at least one succession of + to +, or of — to — 1, for every factor of the form $x + a$, or for every negative root. Hence this rule, viz. "An equation cannot have more positive roots than it has variations from one sign to another, nor more negative roots than it has continuations of the same sign."

In general, this rule merely points out limits which the number of the positive and negative roots of an equation cannot exceed. But it gives no criterion by which we can certainly know that an equation has even one positive or one negative root, much less does it ascertain the exact number of each kind.

But if the proposed equation can be completely resolved into real binomial factors; in which case the total number of its roots will be equal to its dimensions, and consequently to the sum of all the variations from one sign to another, and of all the continuations of the same sign; it is evident that the number of the positive roots will be precisely equal to that of the variations, and the number of the negative roots precisely equal to that of the continuations. In this case, therefore, and in this case only, the rule of Descartes is perfect, ascertaining the exact number of each kind of roots in the proposed equation.

We subjoin some consequences that result from the principles laid down.

"If a polynome $f(x)$ of n dimensions be multiplied by $x-a$, or $x+a$; and, in the first case, if the number of variations from one sign to another be augmented by the odd number $2i+1$; or, in the second case, if the number of continuations of the same sign be augmented by $2i+1$; then the total number of the roots, positive and negative, of the proposed polynome, cannot be greater than $n-2i$."

For, when the multiplier is $x-a$, let m denote the number of the variations from one sign to another in the proposed polynome $f(x)$; then $m+2i+1$ will be the total number of variations in the product $(x-a)\times f(x)$; consequently the total number of continuations in $(x-a)\times f(x)$ will be equal to $(n+1)-(m+2i+1)$, or $n-m-2i$. But a polynome cannot have more negative roots than it has continuations of the same sign; wherefore the number of the negative roots of $(x-a)\times f(x)$ cannot be greater than $n-m-2i$. Now, the two polynomes $f(x)$ and $(x-a)\times f(x)$ have the same negative roots; and hence the number of the negative roots of $f(x)$ cannot exceed $n-m-2i$. But the number of the positive roots of $f(x)$ cannot exceed m; consequently the total number of the roots of $f(x)$ cannot be greater than $m+n-m-2i$; that is, than $n-2i$. And the proposition may be demonstrated in a similar manner when the multiplier is $x+a$.

"If one or several consecutive terms of an equation be wanting, and if the next terms on each side of those wanting have the same sign, the equation cannot have as many roots as it has dimensions."

Let the equation be $P+Q=0$, P and Q denoting the two parts on each side of the terms wanting. Having multiplied $P+Q$ by $x-a$, the product will be $(x-a)P+(x-a)Q$; and it is evident that we may consider P, Q, $(x-a)P$, $(x-a)Q$ as separate polynomes; hence, in each of the polynomes $(x-a)P$ and $(x-a)Q$, there will be at least one more variation from one sign to another than there is in P and Q. Again, in the polynome $P+Q$, there will be a continuation of the same sign in passing from P to Q; because the last term of P is supposed to have the same sign with the first term of Q. On the other hand, because the last term of $(x-a)P$ has a contrary sign to the last term of P; and the first term of $(x-a)Q$, the same sign with the first term of Q, it follows that, in the polynome $(x-a)P+(x-a)Q$, there will be a variation from one sign to another in passing from $(x-a)P$ to $(x-a)Q$. Therefore, on the whole, there will be at least three variations from one sign to another in $(x-a)P+(x-a)Q$, more than there is in $P+Q$. Consequently, by the last proposition, the number of all the roots of the proposed equation must be at least two less than its dimensions.

8. An important inquiry is, to find how many roots, that is, real roots, there are in any proposed equation. Much has been written on this subject, but not very successfully. No general method has been found that is practically useful. Many *criteria* have been contrived, by means of which we can certainly discover that roots are wanting in an equation, although we cannot infer the existence of the roots when the same criteria fail. But great value cannot be attached to such rules, since they are neither sufficient guides in practice, nor have much tendency to throw light on the theory.

Waring first, and nearly about the same time Lagrange, proposed a method which is successful in finding the conditions necessary in order that an equation have as many roots as it has dimensions, and which in all cases points out a limit that the number of the roots cannot exceed. This is effected by an auxiliary equation, and merely by the signs of its co-efficients, without requiring the computation of any of its roots. This procedure answers very well for equations of the third and fourth degrees; and it has even been extended by Waring to those of the fifth degree; but in this last case the calculation is very long, and would be altogether impracticable in the higher orders of equations. It is also not a little probable that this rule employs more conditions than are absolutely necessary for determining the point in question; there being great reason to think that some of them are implied in the rest, and are deducible from them. The method here alluded to depends upon the theory of trinomial divisors; and as it is much referred to by algebraists of the present day, we shall, in a subsequent part of this article, briefly explain the principles on which it is founded.

There is also another way of finding the number of real roots in an equation, which is general for all orders, and requires the solution of such equations only as are of lower dimensions than the one proposed. As to practical utility, indeed, this method is of little avail in equations passing the third and fourth degrees, or at most the fifth degree; but it is nevertheless not without interest, both because it is founded on the principles essential to the inquiry, and because it leads to some useful properties. Algebraists differ from one another in their exposition of this method. Some derive it from the theory of Harriot, namely, that every rational polynome is the product of as many binomial factors as it has dimensions; in which manner of proceeding the impossible roots are the occasion of uncertainty and embarrassment. Others, again, deduce it from the variations of magnitude which a rational polynome undergoes when the unknown quantity is made to pass through all possible degrees of increasing and decreasing. This last mode of investigation seems greatly to deserve the preference, being in reality the only one that is entirely unexceptionable, and requires no principles foreign to the research.

Suppose an equation, $x^n+Ax^{n-1}+Bx^{n-2}\ldots\ldots+Mx+N=0$, which we may denote by $f(x)=0$: substitute $x-i$ in place of x, and put

$$X=f(x)=x^n+Ax^{n-1}\ldots\ldots+Mx+N,$$

$$X'=nx^{n-1}+(n-1)Ax^{n-2}+(n-2)Bx^{n-2}\ldots+M,$$

$$X''=n\cdot\frac{n-1}{2}x^{n-2}+(n-1)\cdot\frac{n-2}{2}Ax^{n-3}+, \&c. \&c.$$

then the function $f(x-i)$ will be transformed into

$$X-X'.i+X''.i^2-X'''.i^3+, \&c.$$

If we suppose the notation of the differential calculus, the same transformation will be thus represented:

$$f(x) - \frac{d \,.\, f(x)}{dx} \,.\, i + \frac{1}{2} \,.\, \frac{d^2 \,.\, f(x)}{dx^2} \,.\, i^2 -, \text{\&c.};$$

which has the advantage of pointing out in what manner the several functions, X′, X″, &c. are derived from one another, and from the first function X, or $f(x)$.

Let α, β, γ, &c. denote the real roots of the equation $X = 0$, or $f(x) = 0$, arranged according to the order of their magnitude, that is, α greater than β, β greater than γ, and so on. In like manner, observing the same order of arrangement, let α', β', γ', &c. represent the roots of $X' = 0$, or $\frac{d \,.\, f(x)}{dx} = 0$; and, for the sake of simplicity, suppose that the equation $X' = 0$ has no equal roots.

The relations which the variations of the polynome X bear to the variations of x, depend upon the functions X′, X″, &c. and principally upon the first of these. If X′ be positive, X will decrease as x decreases; if X′ be negative, X will increase as x decreases; and if X′ pass from being positive to become negative, or the contrary, then x continuing to decrease, X will change from decreasing to increasing, or the contrary; that is, it will attain a minimum or a maximum value. What is here said is the foundation of the method taught in the differential calculus, for finding the maxima and minima of algebraic quantities.

Now, when x has a value great enough, the polynome X′ will have the same sign with its first term, that is, it will be positive; and it will continue positive so long as x is greater than α', the greatest root of the equation $X' = 0$; after which it will become negative. Hence, while x decreases to the limit α', the polynome $f(x)$, which is positive when x is sufficiently great, will continually decrease; and when $x = \alpha'$, $f(x)$ will pass from decreasing to increasing, or it will have a minimum value. Now if this minimum $f(\alpha')$ be positive, $f(x)$ has not decreased to zero, and the given equation will have no root greater than α'. If $f(\alpha') = 0$, then, because the two equations $X = 0$ and $X' = 0$, take place at the same time, the given equation will have two roots equal to α'. (Sect. 6.) *Lastly*, if $f(\alpha')$ be negative, the polynome $f(x)$ has decreased from being positive to be negative; and therefore it has passed through zero, and the given equation will have one root, viz. α greater than α'.

As x continues to decrease from α' to β', the polynome X′ being negative, $f(x)$ will continually increase. At the limit $x = \beta'$, X′ is first equal to zero, and then becomes positive; and $f(x)$ will therefore change from increasing to decreasing, or will attain a maximum value. If this maximum $f(\beta')$ be negative, the polynome $f(x)$ has not increased to zero, and the given equation will have no root between α' and β': if $f(\beta') = 0$, it will have two roots equal to β: and if $f(\beta')$ be positive, $f(x)$, in increasing from the negative quantity $f(\alpha')$ to the positive quantity $f(\beta')$, must have passed through zero, and the given equation will have one root, viz. β, between α' and β'.

In like manner, x continuing to decrease from β' to γ', the polynome $f(x)$ will decrease from the maximum $f(\beta')$ to the minimum $f(\gamma')$: if $f(\gamma')$ be positive, the proposed equation will have no root between β' and γ'; if $f(\gamma') = 0$, it will have two roots equal to γ'; and if $f(\gamma')$ be negative, it will have one root, viz. γ, between the limits β' and γ'.

As the function $f(x)$ must become a minimum or a maximum, or must pass from decreasing to increasing, or the contrary, between every two contiguous roots of the equation $f(x) = 0$; and as the limits where the changes take place are determined by the roots of the equation $X' = 0$; it follows that there must be at least one root of this last equation between every two contiguous roots of the first. Hence the equation $f(x) = 0$ cannot have as many roots as dimensions, unless the equation $X' = 0$ likewise have as many roots as dimensions; and in general we have this rule, which determines a limit that the number of the roots of an equation cannot surpass, although it may fall short of it: "The roots of an equation $f(x) = 0$ cannot exceed in number those of the equation $\frac{d f(x)}{dx} = 0$, by more than one."

But if we can find the roots of the equation $X' = 0$, which is always one degree lower than the proposed equation, we can thence discover exactly both the number and the limits of the roots of this last. For let α', β', γ', &c. be substituted in the polynome $f(x)$, and let the results be arranged in order, viz.

$$\underset{-}{f(\alpha')}, \underset{+}{f(\beta')}, \underset{-}{f(\gamma')}, \underset{+}{f(\delta')}, \text{\&c.}:$$

if these quantities are alternately negative and positive; the first, third, fifth, &c. which are all minima, having the sign *minus;* and the second, fourth, &c. which are all maxima, having the sign *plus;* then the proposed equation $f(x) = 0$ will have just one root more than the equation $X' = 0$. When some of the conditions fail, the roots of the proposed equation will fall short of the number specified. If one maximum have the sign *minus*, or one minimum the sign *plus*, two roots will be wanting in the proposed equation; and in general as many roots will disappear, as there are consecutive minima and maxima that have the same sign deducting one; unless the minima and maxima precede the greatest root, or come after the least root, in which cases there will be as many roots wanting as there are minima and maxima that have the same sign.

Since the series of functions, X, X′, X″, &c. are derived similarly from one another, we may prove, as has been done with respect to the two first, that the roots of any one are contained between the roots of that which follows it. Hence, if the given equation have as many roots as dimensions, every equation in the series will likewise have as many roots as dimensions; and if there be roots wanting in any one, there will be at least as many wanting in every equation preceding it in the series.

The connected equations necessarily terminate in one of the first degree, which gives a limit between the two roots of the quadratic immediately before it; in like manner, the roots of the quadratic are the limits of the roots of the cubic preceding it; and in this manner, by going through all the successive equations, we shall finally arrive at the limits of the roots of the proposed equation. This process has been called *La Methode des Cascades;* but the length of the calculations renders it useless in practice.

The procedure explained above would enable us to find the number of roots in an equation of any order, if we were in possession of rules for solving equations of the inferior degrees. For want of such rules, the practical advantage that can be derived from it is very limited. Mathematicians have therefore turned their attention to determine the point in question in a way that should not require the resolution of equations. They have sought to investigate rational functions of the co-efficients, which, by means of the signs they are affected with in every particular case, might indicate the number of roots the equation possesses. Of this nature is the method which Du Gua has given in the *Mémoires de Paris*, 1741, for finding the conditions necessary in order that an equation have as many roots as dimensions. By a process analogous to that of Du Gua, M. Cauchy, in an excellent *Me-*

moir, published in the sixteenth volume of the *Journal de l'Ecole Polytechnique*, has shown not only that the total number of the roots may in every case be discovered, but likewise that the numbers of the positive and negative roots may be separately ascertained. The principles of both these methods are to be found in the theory explained above; but as many considerations of some intricacy are involved in them, a particular account of them would exceed the limits of this article.

In what goes before, we have supposed that all the roots of the equation $X' = 0$ are unequal; and in order to complete the theory, it remains to notice the consequences that follow when the case is otherwise. Suppose, then, that $X' = (x - \lambda)^i \times Q$: And, in the first place, if λ be a root of the equation $f(x) = 0$, there will in reality be no exception to the general conclusion; because in this case it is known that the polynome $f(x)$ will be divisible by $(x - \lambda)^{i+1}$. (Sect. 6.) Now, the case just mentioned being set aside, if i be an even number, the polynome X', or $(x - \lambda)^i \cdot Q$, will be equal to zero when $x = \lambda$; but it will not change its sign when x, from being less, comes to be greater than λ. Hence the polynome $f(x)$ will neither attain a maximum nor a minimum value at the same limit; and it will have no root, either between λ and the next greater root of the equation $X' = 0$, or between λ and the next less root of the same equation. It appears, therefore, that when i is even, the number of the roots of the equation $f(x) = 0$, and their limits, will depend entirely upon the equation $Q = 0$. Again, when i is an odd number, the polynome X' will be equal to zero when $x = \lambda$, and it will likewise change its sign when x is taken on contrary sides of that limit: Consequently, when $x = \lambda$, the polynome $f(x)$ will be a maximum or a minimum; and the nature of its roots will depend upon the equation $(x - \lambda)\,Q = 0$. It is evident that we may extend the same conclusions to any two adjacent equations in the series,

$$X = 0,\ X' = 0,\ X'' = 0,\ X''' = 0, \text{ \&c.}$$

provided the one which stands lower in the series is reducible to the form $(x - \lambda)^i Q$; and that $x - \lambda$ is not a common divisor of both. We may likewise draw this general inference from the principles that have been explained, viz. "If, in the series of connected equations, any one be found which is divisible by $(x - \lambda)^{2i}$, or $(x - \lambda)^{2i+1}$, at the same time that $x - \lambda$ is not a divisor of the equation immediately preceding, there will be at least $2i$ roots wanting in this last equation, and in all that stand before it in the series."

The following not inelegant proposition is a consequence of what has just been proved: "The number of the roots of an equation of n dimensions, in which $2i$ or $2i + 1$, consecutive terms, are wanting, cannot be greater than $n - 2i$."

Let the equation be represented by

$$P + Q = 0;$$

supposing that $2i$, or $2i + 1$ terms, are wanting between P and Q. Therefore, if the first term of Q contain x^m, the last term of P will contain x^{m+2i+1}, or x^{m+2i+2}. Now, in the series of equations, we shall at length arrive at one from which all the quantities of Q are exterminated; which equation, if we use the notation of the differential calculus, is equivalent to

$$\frac{d^{m+1}P}{dx^{m+1}} = 0;$$

and it is divisible by x^{2i}, or x^{2i+1}: And as the one immediately preceding it in the series, viz.

$$\frac{d^m P}{dx^m} + \frac{d^m Q}{dx^m} = 0,$$

is not divisible by x, it follows, from what has been shown, that there will be at least $2i$ roots wanting in this last equation, and in all those that stand before it; consequently the proposed equation cannot have more than $n - 2i$ roots.

From this we learn that it is not always possible, at least by any operations with real quantities, to transform an equation into another in which any proposed number of the intermediate terms shall be wanting. For the terms to be taken away may be such that the transformed equation could not have the same number of real roots as the one given; but it is impossible, without introducing imaginary quantities, to transform an equation with a certain number of real roots into another with a different number of such roots.

9. In what goes before, we have sought for the roots and binomial divisors in the nature of the polynome. We are now to take an inverted view of the subject, and to consider a rational polynome as produced by the continued multiplication of as many binomial factors as it has dimensions; from which source there arises an interesting set of properties.

If we take the words root and binomial factor strictly in the sense in which we have hitherto used them, and as denoting real quantities only, nothing is more certain than that all polynomes cannot be generated by binomial factors. But it will afterwards be proved that every rational polynome can be completely exhausted by binomial and trinomial divisors; and if we admit the resolution of every trinomial divisor into two imaginary factors, we shall arrive, with all the rigour of which the investigation is capable, at the genesis of equations supposed by Harriot, which represents them as entirely composed of binomial factors, possible or impossible. Besides, in extending to all equations the conclusions obtained from the manner of generating them, it may be observed that the properties so obtained, being ultimately expressed in functions of the co-efficients from which the roots and generating factors have disappeared, are in a manner independent of the method of investigation. Such is the structure of the language of algebra, that the conclusions to which it leads, although deduced by reasoning from a hypothesis not strictly general, are nevertheless true in all cases, when they are finally disengaged from what is peculiar in the analysis.

Suppose a polynome, as

$$x^n - A^{(1)}x^{n-1} + A^{(2)}x^{n-3} \ldots \pm A^{(n-1)}x \mp A^{(n)},$$

which is produced by the multiplication of the n factors,

$$(x - \alpha) \cdot (x - \beta)(x - \gamma)(x - \delta), \text{ \&c.}$$

then, by actually multiplying the factors, and equating the like terms of the equivalent expressions, we shall get

$$A^{(1)} = \alpha + \beta + \gamma + \delta +, \text{ \&c.}$$
$$A^{(2)} = \alpha\beta + \alpha\gamma +, \text{ \&c.} + \beta\gamma +, \text{ \&c.}$$
$$A^{(3)} = \alpha\beta\gamma + \alpha\beta\delta +, \text{ \&c.} + \beta\gamma\delta +, \text{ \&c.}$$
$$A^{(4)} = \alpha\beta\gamma\delta +, \text{ \&c.}$$
&c.

Hence it appears that the co-efficient of the second term of the polynome, or $-A^{(1)}$, is equal to the sum of all the roots with their signs changed; the co-efficient of the third term, or $+A^{(2)}$, to the sum of all the products of every two roots; the co-efficient of the fourth term, or $-A^{(3)}$, to the sum of all the products of every three roots with their signs changed, and so on, the signs of the roots being always changed in the products of an odd number; and finally, the last term is the product of all the roots with their signs changed or not, according as their number is odd or even.

It is evident that the ultimate product of the binomial factors will always be the same, in whatever order they are multiplied; and hence the co-efficients of the polynome will consist of the same products, however the roots be interchanged among one another. Expressions of the kind just mentioned, which have constantly the same value, whatever change is made in the order of the quantities they contain, are called *invariable functions* and *symmetrical functions*. The co-efficients of an equation are the most simple symmetrical functions of the roots, from which it may be required, on the one hand to deduce all other functions of the like kind, and on the other to go back to the roots themselves. Most inquiries relating to equations are connected with one or other of these two problems; of which the first, like most direct methods, is attended with little difficulty, and has been completely solved; while the other, past equations of the fourth degree, has eluded all the attempts of algebraists.

After the co-efficients of the polynome, the next most simple symmetrical functions of the roots are the sums of the squares, cubes, &c. In the universal arithmetic of Sir Isaac Newton, a very elegant rule is given for computing the sum of any proposed powers of the roots; and as this rule is a fundamental point in the theory of equations, we subjoin an elementary investigation of it.

Of the binomial factors before set down, let the first $x-\alpha$ be left out, and having multiplied the rest together, let the product be

$$x^{n-1}-\varphi^{(1)}x^{n-2}+\varphi^{(2)}x^{n-3}-\varphi^{(3)}x^{n-4}+,\&c.;$$

in which expression $\varphi^{(1)}$ is the sum of all the roots β, γ, δ, &c. except the first α; $\varphi^{(2)}$ is the sum of the products of every two of them, and so on. Now, multiply by $x-\alpha$, and the product will be equivalent to the given polynome: hence we get

$$\begin{aligned}
A^{(1)}&=\alpha+\varphi^{(1)},\\
A^{(2)}&=\alpha.\varphi^{(1)}+\varphi^{(2)},\\
A^{(3)}&=\alpha.\varphi^{(2)}+\varphi^{(3)},\\
&\vdots\\
A^{(r)}&=\alpha.\varphi^{(r-1)}+\varphi^{(r)}.
\end{aligned}$$

Again, multiply these formulæ in order by α^{r-1}, α^{r-2}, α^{r-3}, &c.; then

$$\begin{aligned}
\alpha^{r}&=\alpha^{r},\\
A^{(1)}.\alpha^{r-1}&=\alpha^{r}+\alpha^{r-1}.\varphi^{(1)},\\
A^{(2)}.\alpha^{r-2}&=\alpha^{r-1}.\varphi^{(1)}+\alpha^{r-2}.\varphi^{(2)},\\
&\vdots\\
A^{(r-1)}.\alpha&=\alpha^{2}\varphi^{(r-2)}+\alpha.\varphi^{(r-1)},\\
A^{(r)}&=\alpha.\varphi^{(r-1)}+\varphi^{(r)};
\end{aligned}$$

nd, by adding and subtracting alternately, we get

$$\alpha^{(r)}-A^{(1)}.\alpha^{r-1}+A^{(2)}.\alpha^{r-2}\ldots\pm A^{(r-1)}.\alpha \mp A^{(r)}=\mp\varphi^{(r)},$$

n which expression $\varphi^{(r)}$ is the sum of all the products of dimensions of the roots β, γ, δ, &c. leaving out the first α.

In like manner, if we leave out the factor $x-\beta$, and multiply all the rest, and proceed as before, we shall get

$$\beta^{r}-A^{(1)}\beta^{r-1}+A^{(2)}\beta^{r-2}\ldots\pm A^{(r-1)}\beta\mp A^{(r)}=\pm\varphi'^{(r)},$$

the symbol $\varphi'^{(r)}$ being the sum of the products of r dimensions of all the roots, α, γ, δ, except the second β.

And if we next leave out the factor $x-\gamma$, and follow a like procedure, we shall get

$$\gamma^{r}-A^{(1)}.\gamma^{r-1}+A^{(2)}.\gamma^{r-2}\ldots\pm A^{(r-1)}.\gamma\mp A^{(r)}=\mp\varphi''^{(r)};$$

where $\varphi''^{(r)}$ represents the sum of the products of r dimensions of all the roots α, β, δ, &c. except the third γ.

If we procced similarly till every one of the n factors is left out in its turn, and then add all the results, we shall get

$$S_{r}-A^{(1)}S_{r-1}+A^{(2)}S_{r-2}\ldots\pm A^{(r-1)}S_{1}\mp nA^{(r)}=\mp\left\{\varphi^{(r)}+\varphi'^{(r)}+\varphi''^{(r)}+,\&c.\right\};$$

in which expression S_r is written for the sum of the r powers of the roots; S_{r-1} for the sum of the $(r-1)$ powers, and so on.

Every product in any one of the aggregate quantities $\varphi^{(r)}$, $\varphi^{(r)}$, $\varphi''^{(r)}$, &c., is found in $A^{(r)}$, which is the sum of the products of r dimensions of all the roots; and hence it is easy to perceive that the sum of all the aggregates must be a multiple of $A^{(r)}$. Take any product in $A^{(r)}$; then that product will not be contained in r of the quantities $\varphi^{(r)}, \varphi'^{(r)}, \varphi''^{(r)}$, &c.; because, in so many of them, one or other of the letters of the product will be wanting; but the same product will be contained once in every one of the $n-r$ remaining quantities, because in every one of these all the letters of the product will be contained. Every product in $A^{(r)}$ is therefore repeated $n-r$ times in the sum of the quantities $\varphi^{(r)}, \varphi'^{(r)}, \varphi''^{(r)}$, &c.; consequently,

$$\varphi^{(r)}+\varphi'^{(r)}+\varphi''^{(r)}+,\&c.=(n-r)\,A^{(r)}.$$

Substitute this value in the formula obtained above, and after transposing and cancelling $nA^{(r)}$, which appears with contrary signs, we shall get

$$S_{r}-A^{(1)}S_{r-1}+A^{(2)}S_{r-2}\ldots\pm A^{r-1}S\mp rA^{(r)}=0.$$

This is the rule of Sir Isaac Newton, and contains all his particular formulæ, as will readily appear by putting 1, 2, 3, &c. successively for r.

The preceding formula will enable us to compute, in succession, the sums of all the positive powers of the roots, both when r is less and when it is greater than the dimensions of the equation. But, in applying the formula in the latter case, we must observe that all the co-efficients of the polynome after $A^{(r)}$ are wanting, or equal to nothing.

If, in the first step of the preceding investigation, we take the co-efficients that follow $A^{(r)}$, we shall get

$$\begin{aligned}
A^{(r+1)}&=\alpha.\varphi^{(r)}+\varphi^{(r+1)},\\
A^{(r+2)}&=\alpha.\varphi^{(r+1)}+\varphi^{(r+2)},
\end{aligned}$$

$$\mathrm{A}^{(n-1)} = \alpha\varphi^{(n-2)} + \varphi^{(n-1)},$$

$$\mathrm{A}^{(n)} = \alpha \cdot \varphi^{(n-1)}.$$

And, by first dividing by α, α^2, α^3, &c. in order, and then subtracting and adding alternately, we shall obtain

$$\frac{\mathrm{A}^{(r+1)}}{\alpha} - \frac{\mathrm{A}^{(r+2)}}{\alpha^2} + \frac{\mathrm{A}^{(r+3)}}{\alpha^3} -, \&c. = \varphi^{(r)}.$$

In a similar manner we get

$$\frac{\mathrm{A}^{(r+1)}}{\beta} - \frac{\mathrm{A}^{(r+2)}}{\beta^2} + \frac{\mathrm{A}^{(r+3)}}{\beta^3} -, \&c. = \varphi'^{(r)},$$

$$\frac{\mathrm{A}^{(r+1)}}{\gamma} - \frac{\mathrm{A}^{(r+2)}}{\gamma^2} + \frac{\mathrm{A}^{(r+3)}}{\gamma^3} -, \&c. = \varphi''^{(r)}, \&c.$$

Therefore, by adding all these formulæ, and substituting for the sum of $\varphi^{(r)}$, $\varphi'^{(r)}$, &c. the value of it already found, we shall finally obtain

$$\mathrm{A}^{(r+1)}\,\mathrm{S}_{-1} - \mathrm{A}^{(r+2)}\,\mathrm{S}_{-2} + \mathrm{A}^{(r+3)}\,\mathrm{S}_{-3} -, \&c.$$
$$= (n-r)\,\mathrm{A}^{(r)},$$

the symbols S_{-1}, S_{-2}, &c. being put for the sums of the negative powers of the roots according to the indices underwritten. This formula will enable us to compute the sums of the negative powers of the roots.

If, in the formula for the sums of the positive powers of the roots, we make r successively equal to 1, 2, 3, &c. we shall get

$$\mathrm{A}^{(1)} = \mathrm{S}_1,$$
$$-2\mathrm{A}^{(2)} = -\mathrm{A}^{(1)}\,\mathrm{S}_1 + \mathrm{S}_2,$$
$$3\mathrm{A}^{(3)} = \mathrm{A}^{(2)}\,\mathrm{S}_1 - \mathrm{A}^{(1)}\,\mathrm{S}_2 + \mathrm{S}_3,$$
$$-4\mathrm{A}^{(4)} = -\mathrm{A}^{(3)}\,\mathrm{S}_1 + \mathrm{A}^{(2)}\,\mathrm{S}_2 - \mathrm{A}^{(1)}\,\mathrm{S}_3 + \mathrm{S}_4, \&c.$$

and from this we learn that the quantities S_1, S_2, S_3, &c. may be found by means of this expression, viz.

$$\frac{\mathrm{A}^{(1)} - 2\mathrm{A}^{(2)}\,z + 3\mathrm{A}^{(3)}\,z^2 \ldots \pm \mathrm{A}^{(n)}\,z^{n-1}}{1 - \mathrm{A}^{(1)}\,z + \mathrm{A}^{(2)}z^2 \ldots \pm \mathrm{A}^{(n)}\,z^n} = \mathrm{S}_1$$
$$+ \mathrm{S}_2 \cdot z + \mathrm{S}_3 \cdot z^2 +, \&c.$$

for if we multiply the series on the right-hand side of the sign of equality, by the denominator of the fraction on the other side, and then equate the co-efficients of the product to the like co-efficients of the numerator, we shall obtain the very formulæ set down above. Hence the sums of the powers of the roots expressed in terms of the co-efficients of the polynome will be found by developing the fraction in a series. In effecting the development different analytical methods may be followed; and the quantities sought will thus be obtained by different rules, or exhibited in expressions of different forms, such as those given by Waring, Vandermonde, Euler, and La Grange.

And in like manner, if, in the formula for the sums of the negative powers of the roots, we make r successively equal to $n-1$, $n-2$, $n-3$, &c. we shall get

$$\mathrm{A}^{(n-1)} = \mathrm{A}^{(n)}\,\mathrm{S}_{-1},$$
$$-2\mathrm{A}^{(n-2)} = -\mathrm{A}^{(n-1)}\,\mathrm{S}_{-1} + \mathrm{A}^{(n)}\,\mathrm{S}_{-2},$$
$$3\mathrm{A}^{(n-3)} = \mathrm{A}^{(n-2)}\,\mathrm{S}_{-1} - \mathrm{A}^{(n-1)}\,\mathrm{S}_{-2} + \mathrm{A}^{(n)}\mathrm{S}_{-3},$$
$$-4\mathrm{A}^{(n-4)} = -\mathrm{A}^{(n-3)}\,\mathrm{S}_{-1} + \mathrm{A}^{(n-2)}\,\mathrm{S}_{-2}$$
$$- \mathrm{A}^{(n-1)}\,\mathrm{S}_{-3} + \mathrm{A}^{(n)}\,\mathrm{S}_{-4},$$

&c.

from which it appears that the values of all the quantities S_{-1}, S_{-2}, S_{-3}, &c. will be obtained by means of this expression, viz.

$$\frac{\mathrm{A}^{(n-1)} - 2\mathrm{A}^{(n-2)}\,z + 3\mathrm{A}^{(n-3)}\,z^2 -, \&c.}{\mathrm{A}^{(n)} - \mathrm{A}^{(n-1)}\,z + \mathrm{A}^{(n-2)}\,z^2 -, \&c.} = \mathrm{S}_{-1}$$
$$+ \mathrm{S}_{-2} \cdot z + \mathrm{S}_{-3} \cdot z^2 +, \&c.$$

Two kinds of quantities only can enter into any rational and symmetrical function of the roots of an equation; and these are the sums of the like powers of the roots, and the sums of such products as, $\alpha^{i}\,\beta^{i'}\,\gamma^{i''}$, &c. which arise from multiplying different powers of the roots, two and two, three and three, &c. We shall now shortly point out in what manner the latter sums are deduced from the sums of the like powers, for the computation of which rules have already been given; by which means we shall be enabled to find the value of any proposed function of the kind above mentioned.

Let it be required to find the sum of all the products, such as $\alpha^{i}\beta^{i'}$, that arise from combining two powers of the roots in all possible ways; which sum may be denoted by the symbol $\Sigma \,.\, \alpha^{i}\beta^{i'}$. Now it is evident that the product, $\mathrm{S}_i \times \mathrm{S}_{i'}$, will contain two sorts of terms only, namely, powers of the roots, such as $\alpha^{i+i'}$, and the products of which the sum is sought; therefore

$$\Sigma \,.\, \alpha^{i}\beta^{i'} = \mathrm{S}_i \times \mathrm{S}_{i'} - \mathrm{S}_{i+i'}.$$

Next let it be required to find $\Sigma \,.\, \alpha^{i}\beta^{i'}\gamma^{i''}$, or the sum of all the products of three powers of the root. Now $\Sigma \,.\, \alpha^{i}\beta^{i'} \times \mathrm{S}_{i''}$ will contain three sorts of terms, namely, products, such as $\alpha^{i+i''}\,\beta^{i'}$ and $\alpha^{i'+i''}\,\beta^{i}$, in which two roots only are combined, and the products of which the sum is required; therefore

$$\Sigma \,.\, \alpha^{i}\beta^{i'}\gamma^{i''} = \Sigma\alpha^{i}\beta^{i'} \times \mathrm{S}_{i''}$$
$$- \Sigma \,.\, \alpha^{i+i''}\beta^{i'}$$
$$- \Sigma \,.\, \alpha^{i'+i''}\beta^{i}:$$

but, according to the last case,

$$\Sigma \,.\, \alpha^{i+i''}\,\beta^{i'} = \mathrm{S}_{i+i''} \times \mathrm{S}_{i'} - \mathrm{S}_{i+i'+i''},$$
$$\Sigma \,.\, \alpha^{i'+i''}\,\beta^{i} = \mathrm{S}_{i'+i''} \times \mathrm{S}_{i} - \mathrm{S}_{i+i'+i''}:$$

wherefore

$$\Sigma \,.\, \alpha^{i}\beta^{i'}\gamma^{i''} = \mathrm{S}_i \times \mathrm{S}_{i'} \times \mathrm{S}_{i''}$$
$$- \mathrm{S}_{i+i'} \times \mathrm{S}_{i''}$$
$$- \mathrm{S}_{i+i''} \times \mathrm{S}_{i'}$$
$$- \mathrm{S}_{i'+i''} \times \mathrm{S}_{i}$$
$$+ 2\mathrm{S}_{i+i'+i''}.$$

In like manner, when four different powers of the roots are multiplied together, we get

$$\Sigma . \alpha^{i}\beta^{i'}\gamma^{i''}\,\delta^{i'''} = \Sigma \,.\, \alpha^{i'}\,\beta^{i'}\,\gamma^{i''} \times \mathrm{S}_{i'''}$$
$$- \Sigma \,.\, \alpha^{i+i'''}\,\beta^{i'}\,\gamma^{i''}$$
$$- \Sigma \,.\, \alpha^{i'+i'''}\,\beta^{i}\,\gamma^{i''}$$
$$- \Sigma \,.\, \alpha^{i''+i'''}\,\beta^{i'}\,\gamma^{i};$$

and we have only to apply the preceding case in order to obtain the expression of the quantity sought in terms of the sums of the like powers of the roots.

According to the procedure just explained, the case where any number of powers are multiplied together, is reduced to the simpler case where the powers multiplied are one less. There would be no great difficulty in deducing a general formula for the sum when the products contain any proposed number of different powers; but this would lead to calculations incompatible with the length of this article; and it may be doubted whether the use of such a formula is preferable in any cases likely to occur in practice, to the application of the principles here laid down.

The theory of symmetrical functions is of the most extensive use in every branch of the doctrine of equations. Thus, if it be required to form an equation, the roots of which shall be any combinations of the roots of a given equation; it is manifest that the co-efficients of the equation sought will be symmetrical functions of the roots of the given equation; and hence they may be found by calculating these functions in terms of the co-efficients of the given equation.

The theory of symmetrical functions is also of use in approximating to the roots of numerical equations. Sir Isaac Newton seems to have had this application in view in giving his rule for computing the sums of the like powers of the roots. He observes that the powers of a great number increase in a much higher ratio than the same powers of less numbers; and hence the $2r^{\text{th}}$ power of the greatest root of an equation will approach nearer to the sum of the $2r^{\text{th}}$ powers of all the roots as r is greater. Wherefore, neglecting the distinction between positive and negative roots, if we calculate S_{2r}, and then extract its $2r^{\text{th}}$ root, we shall have an approximation to the root of the equation greatest in point of magnitude; and the approximation will be so much more accurate as r is greater.

But there is a more convenient way of approximating to the greatest and least roots of an equation, by means of symmetrical functions. For, since

$$S_{r+1} = \alpha^{r+1} + \beta^{r+1} +, \&\text{c.}$$

$$S_r = \alpha^r + \beta^r +, \&\text{c.}$$

we have

$$\frac{S_{r+1}}{S_r} = \alpha \cdot \frac{1 + \dfrac{\beta^{r+1}}{\alpha^{r+1}} +, \&\text{c.}}{1 + \dfrac{\beta^r}{\alpha^r} +, \&\text{c.}};$$

Now, α being the greatest root, the fraction on the right-hand side will approach to unit when r is sufficiently large, in which case $\dfrac{S_{r+1}}{S_r}$ will be nearly equal to α. Hence, if we compute a series of consecutive sums, viz. S_r, S_{r+1}, S_{r+2}, &c.; the values

$$\frac{S_{r+1}}{S_r}, \frac{S_{r+2}}{S_{r+1}}, \frac{S_{r+3}}{S_{r+2}}, \&\text{c.}$$

will approach nearer and nearer to the greatest root of the equation.

In like manner, if we take the sums of the negative powers of the roots, we shall have

$$\frac{S_{-r}}{S_{-r-1}} = \alpha \cdot \frac{1 + \dfrac{\alpha}{\beta^r} +, \&\text{c.}}{1 + \dfrac{\alpha^{r+1}}{\beta^{r+1}} +, \&\text{c.}};$$

from which it appears that $\dfrac{S_{-r}}{S_{-r-1}}$ will approximate so much more to α, the least root of the equation, as r is greater.

Trinomial Divisors.

10. We proceed next to consider the trinomial divisors of a given polynome; and, in order to avoid reference to other treatises, we shall begin with a short investigation of a preliminary point.

We have this identical expression,

$$x^2 - y^2 = (x+y) \cdot (x-y);$$

consequently,

$$(x^2 - y^2)^n = (x+y)^n \cdot (x-y)^n;$$

and again,

$$(x^2 - y^2)^n = \frac{1}{4} \cdot \left\{ (x+y)^n + (x-y)^n \right\}^2 - \frac{1}{4} \cdot \left\{ (x+y)^n - (x-y)^n \right\}^2$$

Now, using the letters H and G as the characteristics of the particular functions under consideration, let

$$\text{H}_n(x, y^2) = \frac{1}{2} \cdot \left\{ (x+y)^n + (x-y)^n \right\},$$

$$\text{G}_n(x, y^2) = \frac{1}{2} \cdot \frac{(x+y)^n - (x-y)^n}{y};$$

or by expanding the binomial quantities in series,

$$\text{H}_n(x, y^2) = x^n + n \cdot \frac{n-1}{2} \cdot x^{n-2} y^2 +, \&\text{c.}$$

$$\text{G}_n(x, y^2) = n x^{n-1} + n \cdot \frac{n-1}{2} \cdot \frac{n-2}{3} x^{n-3} y^2 +, \&\text{c.};$$

then, by means of these notations, the preceding expression will be thus written, viz.

$$(x^2 - y^2)^n = \left\{ \text{H}_n(x, y^2) \right\}^2 - y^2 \cdot \left\{ \text{G}_n(x, y^2) \right\}^2.$$

This equation is identical; that is, when the expressions on both sides of the sign of equality are expanded in series of terms containing the powers of y^2, they will consist of the same quantities with the same signs. It is evident, therefore, that the equation will still be identical if we change y^2 into $-y^2$; for by this change the simple quantities of the developed expressions will not be affected, and no alteration will be produced, except in the signs of the odd powers of y^2, which will now be contrary to what they were before. We therefore have

$$(x^2 + y^2)^n = \left\{ \text{H}_n(x, -y^2) \right\}^2 + y^2 \cdot \left\{ \text{G}_n(x, -y^2) \right\}^2;$$

in which equation it is to be observed that the functional expressions are not, as in the former instance, susceptible of an abridged algebraic notation, at least without introducing a new sign; but they can be exhibited in series, viz.

$$\text{H}_n(x, -y^2) = x^n - n \cdot \frac{n-1}{2} \cdot x^{n-2} y^2 + n \cdot \frac{n-1 \cdot n-2 \cdot n-3}{2 \cdot 3 \cdot 4} x^{n-4} y^2 -, \&\text{c.}$$

$$\text{G}_n(x, -y^2) = n x^{n-1} - n \cdot \frac{n-1 \cdot n-2}{2 \cdot 3} x^{n-3} y^2 +, \&\text{c.}$$

Now put $x = r \cos. \varphi$, $y = r \sin. \varphi$, $x^2 + y^2 = r^2$; and let $\varphi^{(n)}$ denote an arc, depending, in a certain manner, not yet discovered, upon the arc φ and the index n; then, in consequence of the equation obtained above, we shall have

$$r^n \cos. \varphi^{(n)} = \text{H}_n (x, -y^2),$$

$$r^n \sin. \varphi^{(n)} = y \text{G}_n (x, -y^2).$$

Again, multiply both sides of the same equation last referred to by $x^2 + y^2$; then

$$(x^2+y^2)^{n+1} = \left\{ x \,.\, \mathrm{H}_n(x,-y^2) - y^2 \mathrm{G}_n(x,-y^2) \right\}^2$$

$$+ y^2 \left\{ \mathrm{H}_n(x,-y^2) + x\mathrm{G}_n(x,-y^2) \right\}^2,$$

but, since the equation alluded to is general for all the values of n, we may write $n+1$ for n; and thus we get

$$(x^2+y^2)^{n+1} = \left\{ \mathrm{H}_{n+1}(x,-y^2) \right\}^2$$

$$+ y^2 \left\{ \mathrm{G}_{n+1}(x,-y^2) \right\}^2:$$

therefore, by comparing the two values of $(x^2+y^2)^{n+1}$

$$\mathrm{H}_{n+1}(x,-y^2) = x \,.\, \mathrm{H}_n(x,-y^2) - y^2\mathrm{G}(x,-y^2),$$

$$y\mathrm{G}_{n+1}(x,-y^2) = y\mathrm{H}_n(x,-y^2) + yx\mathrm{G}n(x,-y^2):$$

and finally, by substituting the values of the functions in terms of the arcs, φ, $\varphi^{(n)}$, $\varphi^{(n+1)}$, we shall obtain

$$\cos.\varphi^{(n+1)} = \cos.\varphi\cos.\varphi^{(n)} - \sin.\varphi\sin.\varphi^{(n)} = \cos.(\varphi^{(n)}+\varphi),$$

$$\sin.\varphi^{(n+1)} = \cos.\varphi\sin.\varphi^{(n)} + \sin.\varphi\cos.\varphi^{(n)} = \sin.(\varphi^{(n)}+\varphi),$$

$$\varphi^{(n+1)} = \varphi^{(n)} + \varphi.$$

Now, if we make n successively equal to 1, 2, 3, &c. the results will be,

$$\varphi^{(2)} = 2\varphi,$$

$$\varphi^{(3)} = 3\varphi,$$

&c.

and generally, $\varphi^{(n)} = n\varphi$.

Thus it appears that

$$r^n \cos.\, n\varphi = \mathrm{H}_n(x,-y^2),$$

$$r^{n-1} \times \frac{\sin.n\varphi}{\sin.\varphi} = \mathrm{G}_n(x,-y^2);$$

or, if we take the expanded expressions of the functions,

$$r^n \cos.\, n\varphi = x^n - n\,.\frac{n-1}{2}x^{n-2}y^2 +$$

$$n\,.\frac{n-1}{2}\,.\frac{n-2}{3}\,.\frac{n-3}{4}x^{n-4}y^2 -, \text{\&c.}$$

$$r^{n-1} \times \frac{\sin.n\varphi}{\sin.\varphi} = nx^{n-1} - n.\frac{n-1}{2}\,.\frac{n-2}{3}x^{n-3}y^2 +, \text{\&c.}$$

in which formulæ, $x = r\cos.\varphi$, $y = r\sin.\varphi$.

The functions here designated by the letters H and G may be expressed by means of the imaginary sign; for we have

$$\mathrm{H}_n(x,-y^2) = \frac{(x+y\sqrt{-1})^n + (x-y\sqrt{-1})^n}{2},$$

$$\mathrm{G}_n(x,-y^2) = \frac{(x+y\sqrt{-1})^n - (x-y\sqrt{-1})^n}{2y\sqrt{-1}};$$

And, in the case of $r=1$, the formulæ obtained above are equivalent to the expressions known in analysis since the time of Dr Moivre, viz.

$$\cos.\, n\varphi = \frac{(\cos.\varphi + \sin.\varphi\sqrt{-1})^n + (\cos.\varphi - \sin.\varphi\sqrt{-1})^n}{2}$$

$$\sin.\, n\varphi = \frac{(\cos.\varphi + \sin.\varphi\sqrt{-1})^n - (\cos.\varphi - \sin.\varphi\sqrt{-1})^n}{2\sqrt{-1}}.$$

But the mode of investigation we have followed is rigorous; and it has the advantage of leading to the true import of the imaginary sign, and of putting in a clear light its real effect in analytical operations. The real use of this sign may be shortly described by saying that it performs for even and odd functions the same office that the negative sign does for ordinary functions; in other words, when, by means of the ordinary operations of analysis, it has been proved that an even or odd function of an indeterminate quantity is equal to zero, it is by means of the impossible sign that the same equation is extended to the case when the square of the indeterminate quantity is negative. Every function of the indeterminate quantity x may be thus represented, viz.

$$\varphi(x^2) \pm x\Psi(x^2);$$

and the substitution of $x\sqrt{-1}$ in place of x, has no other effect than to change the preceding expression into the one following, viz.

$$\varphi(-x^2) \pm x\sqrt{-1}\,.\,\Psi(-x^2);$$

and from this it is obvious, that the same operations which, in the one case, lead us to the equations $\varphi(x^2)=0$ and $x\Psi(x^2)=0$, will, in the other, necessarily conduct us to the equations $\varphi(-x^2)=0$ and $x\,.\,\Psi(-x^2)=0$. It is to be observed, too, that the truth of the two latter equations is involved in that of the former. For the former equations cannot be generally true for all values of x^2, unless they are identical, or consist of equal quantities with opposite signs that mutually destroy one another; in which case the latter equations will also be identical. The sign of impossibility, as it has been called, is therefore one as truly significant as any other in analysis. It has, indeed, no consistent meaning when we consider it as only affecting x, or the indeterminate quantity to which it is joined; but it becomes perfectly intelligible when we contemplate the real changes produced by it in the functions of even and odd dimensions, in which its conclusions are always ultimately expressed. When the true import and real effect of the imaginary sign are clearly apprehended, the truth of its conclusion is no longer doubtful or mysterious, but follows as a necessary consequence of a fundamental principle of analytical language. Proceeding on this principle, we may even lay aside the imaginary character; and, in every particular case, with the assistance of a proper notation, arrive, by the ordinary operations, at the same conclusion to which it leads, as has been done in the preceding instance. It is to be observed further, that the imaginary arithmetic is not merely a short method of calculation convenient in practice, and that it may be dispensed with; it is strictly a necessary branch of analysis, without which, or some equivalent mode of investigation, that science would be extremely imperfect. The equations $\varphi(x^2)=0$ and $x\Psi(x^2)=0$, are unchangeable by any operations with the signs commonly received, by the use of which alone it is impossible to deduce, in a direct manner, the related equations $\varphi(-x^2)=0$ and $x\Psi(-x^2)=0$: although the latter are equally true, of as frequent occurrence, and as extensive application, as the former. Without the impossible sign the operations of algebra would, therefore, be defective; since there are analytical truths that could not be investigated in a direct manner by means of the elementary signs usually admitted. It is to supply this defect that the imaginary arithmetic has been introduced, and has grown up to be an extensive branch of analysis; advancing at first by slow steps, because the true import of the character it employs, and the real effect of its operations, were neither clearly perceived nor fully understood. But having premised what is conducive to our present purpose, we proceed to the investigation of the trinomial divisors of rational functions.

11. Every polynome of odd dimensions having at least one binomial factor, it may, by dividing by that factor, be reduced to another polynome one degree lower. And hence, in this part of our subject, we may confine our attention to polynomes of even dimensions. We may also suppose that the even polynomes under consideration have no double, triple, &c. factors of any kind: since, in case

ny such are present, they can be found separately and liminated by division.

Suppose, then, that $f(x)$ represents any polynome of ven dimensions; let $\varrho + u$ be substituted in place of x; nd, by using the notation of the differential calculus, the iven polynome will be transformed into

$$f(\varrho) + \frac{d.f(\varrho)}{d\varrho} \cdot u + \frac{1}{2} \cdot \frac{d^2 f(\varrho)}{d\varrho^2} \,.\, u^2 +, \&c.$$

Since $f(x)$ is an even po.ynome, the equation $\frac{df(x)}{dx} = 0$ ill be one of odd dimensions, having at least one root. et ϱ be the sole root of $\frac{df(x)}{dx} = 0$, when it has but one, nd the greatest root when it has several; then, because $\frac{f(\varrho)}{d\varrho} = 0$, the transformed function will become

$$f(\varrho) + \frac{1}{2} \cdot \frac{d^2 f(\varrho)}{d\varrho^2} u^2 + \frac{1}{6} \cdot \frac{d^3 f(\varrho)}{d\varrho^3} \,.\, u^3 +, \&c.$$

It readily appears, from what was formerly proved (Sect.), that ϱ, the greatest root of $\frac{df(x)}{dx} = 0$, exceeds the reatest root of any of the equations, $\frac{1}{2} \cdot \frac{d^2 f(x)}{dx^2} = 0$, $. \frac{d^3 f(x)}{dx^3} = 0$, &c.; and because, in any equation, the ıbstitution of a value greater than the greatest root must ive a positive result, all the quantities $\frac{1}{2} \cdot \frac{d^2 f(\varrho)}{d\varrho^2}$, $\frac{1}{6} \cdot \frac{d^3 f(\varrho)}{d\varrho^3}$, c. will be positive. With regard to $f(\varrho)$ it may be either ositive or negative, but not equal to zero; since this last se can happen only when the polynome has equal roots. he original polynome will, therefore, assume this form, z.

$$= y + A^{(2)}u^2 + A^{(3)}u^3 + A^{(4)}u^4 \ldots + A^{(2n-1)}u^{2n-1}$$

u^{2n}, in which expression y, $A^{(2)}$, $A^{(3)}$, &c. represent y positive quantities.

The most interesting proposition in the branch of the bject under consideration, is to prove that every polyme of even dimensions has a quadratic divisor, either the form $(u + \alpha)^2 - \tau^2$, which admits two real binoial factors, or of the form $(u - \alpha)^2 + \tau^2$, which has two aginary factors. By the preceding transformation this oposition is brought under two cases, according as y is fected with the sign *minus* or *plus*; the quadratic divir being always of the form $(u + \alpha)^2 - \tau^2$ in the first se, and always of the form $(u - \alpha)^2 + \tau^2$ in the other se; a distinction that agrees with what was before oved, Sect. 8.

Now the first of these cases is attended with no diffilty. For two values of u, one negative and one positive, ay be found that will satisfy the equation, Sect. 4.

$$y = A^{(2)}u^2 + A^{(3)}u^3 + A^{(4)}u^4 \ldots + u^{2n}.$$

f these values, it is obvious that the negative one will always greater than the positive one; and they may, erefore, be represented by $-(\tau + \alpha)$ and $\tau - \alpha$: where re, the polynome

$$-y + Au^2 + A^{(3)}u^3 + A^{(4)}u^4 \ldots\ldots + u^{2n},$$

ll be divisible by each of the binomial factors,

$$u + \tau + \alpha,$$
$$u - \tau + \alpha;$$

d likewise by the quadratic factor,

$$(u + \alpha)^2 - \tau^2,$$

oduced by their multiplication.

But the same mode of reasoning will not apply when y has the sign *plus*; in which case the demonstration must be deduced from other principles.

12. If we put

$$\varphi(u) = A^{(2)}u^2 + A^{(3)}u^3 + A^{(4)}u^4 \ldots + u^{2n},$$

the transformed polynome, supposing y to have the sign *plus*, will become

$$y + \varphi(u).$$

Let $(u - \alpha)^2 + \tau^2$ be a quadratic divisor of this polynome, and put $u - \alpha = z$, or $u = \alpha + z$; then, by substituting $\alpha + z$ for u, and writing all the terms of the transformed function $\varphi(\alpha + z)$ in two lines, one containing all the even and the other all the odd powers of z, the polynome $y + \varphi(u)$ will be equal to

$$y + \varphi(\alpha) + \frac{1}{2} \cdot \frac{d^2\varphi(\alpha)}{d\alpha^2} \cdot z^2 + \frac{1}{24} \cdot \frac{d^4\varphi(\alpha)}{d\alpha^4} z^4 +, \&c.$$
$$+ z \,.\, \left\{ \frac{d\varphi(\alpha)}{d\alpha} + \frac{1}{6} \cdot \frac{d^3\varphi(\alpha)}{d\alpha^3} \cdot z^2 +, \&c. \right\}.$$

By the same substitution of z for $u - \alpha$, the divisor $(u - \alpha)^2 + \tau^2$ is changed into the binomial quantity $z^2 + \tau^2$; which will be a divisor of each of the preceding lines, if $-\tau^2$, when it is substituted for z^2, render each of them equal to zero, Sect. 3. Hence we obtain the two following equations, viz.

$$0 = y + \varphi(\alpha) - \frac{1}{2} \cdot \frac{d^2\varphi(\alpha)}{d\alpha^2} \tau^2 + \frac{1}{24} \cdot \frac{d^4\varphi(\alpha)}{d\alpha^4} \tau^4 -, \&c.$$
$$0 = \frac{d\varphi(\alpha)}{d\alpha} - \frac{1}{6} \cdot \frac{d^3\varphi(\alpha)}{d\alpha^3} \tau^2 +, \&c. \qquad \text{(C)}$$

If two numbers, α and τ^2, can be found that will satisfy these equations, it is evident that $z^2 + \tau^2$ will be a divisor of each of the two lines that compose the transformed function $y + \varphi(\alpha + z)$; consequently it will be a divisor of the sum of both lines, or of the function itself, that is, $(u - \alpha)^2 + \tau^2$ will be a divisor of the proposed polynome $y + \varphi(u)$. We are now to prove that two such numbers may be found.

Substitute $\lambda^2 \alpha^2 - s$ for τ^2 in the equations (C), λ being a quantity to be afterwards determined; and, in order to shorten expressions, put

$$M = \varphi(\alpha) - \frac{1}{2} \cdot \frac{d^2\varphi(\alpha)}{d\alpha^2} (\lambda^2 \alpha^2 - s) + \frac{1}{24} \cdot \frac{d^4\varphi(\alpha)}{a\alpha^4} \times$$
$$(\lambda^2 \alpha^2 - s)^2 - \&c.$$
$$N = \frac{d\varphi(\alpha)}{d\alpha} - \frac{1}{6} \cdot \frac{d^3\varphi(\alpha)}{d\alpha^3} (\lambda^2 \alpha^2 - s) +, \&c.$$

And the two equations (C) will be thus written, viz.

$$y + M = 0,$$
$$N = 0.$$

In these equations α and s are always supposed to represent positive numbers, in which case the equation $N = 0$ cannot take place when s is greater than $\lambda^2 \alpha^2$; for then all the terms of N would be positive.

Considering N as a function of α, the part of it that does not contain α is evidently

$$A^{(3)} s + A^{(5)} s^2 + A^{(7)} s^3 +, \&c.$$

which is always positive. The highest power of α contained in the same function is α^{2n-1}; and we shall obtain all the terms of N that contain this power by putting α^{2n} for $\varphi(\alpha)$ in the expression

$$\frac{d\varphi(\alpha)}{d\alpha} - \frac{1}{6} \cdot \frac{d^3\varphi(\alpha)}{d\alpha^3} \lambda^2 \alpha^2 + \frac{1}{120} \cdot \frac{d^5\varphi(\alpha)}{d\alpha^5} \lambda^4 \alpha^4 -, \&c.;$$

which terms are therefore as follows, viz.

$$\alpha^{2n-1} \Big\{ 2n - 2n . \frac{2n - 1 \,.\, 2n - 2}{2 \,.\, 3} \lambda^2 +$$

$$2n.\frac{2n-1.2n-2.2n-3.2n-4}{2\;.\;3\;.\;4\;.\;5}\lambda^4+,\&c.\Big\}.$$

Now, in the expression obtained in Sect. 10, viz.

$$r^{2n-1}\times\frac{\text{sin. }2n\varphi}{\text{sin. }\varphi}=2nx^{2n-1}-2n.\frac{2n-1.2n-2}{2\;.\;3}x^{2n-3}y^2+,\&c.$$

if we put $\lambda^2=\frac{y^2}{x^2}=\text{tan.}^2\,\varphi$, and divide both sides by $x^{2n-1}=r^{2n-1}\text{ cos.}^{2n-1}\varphi$; we shall obtain

$$\frac{\text{sin. }2n\varphi}{\text{sin. }\varphi}\times\frac{1}{\text{cos.}^{2n-1}\varphi}=2n-2n\cdot\frac{2n-1.2n-2}{2\;.\;3}\lambda^2+,\&c.;$$

from which formula it follows, that the polynome on the right-hand side of the sign of equality will be equal to nothing, where $\varphi=\pm\frac{m}{n}\times 90°$, m being any integer number less than n, zero not included. Wherefore the first, third, &c. roots of the polynome will be expressed by the formula

$$\lambda^2=\text{tan.}^2\frac{2k+1}{n}\cdot 90,$$

$2k+1$ representing any odd number less than n; and the second, fourth, &c. roots by the formula

$$\lambda^2=\text{tan.}^2\frac{2k+2}{n}\cdot 90°,$$

$2k+2$ being any even number less than n. And it is evident that the polynome will be negative for every value of λ^2 that lies between any odd root and the next even root, that is, for every value between these limits, viz.

$$\lambda^2>\text{tan.}^2\frac{2k+1}{n}\cdot 90°,$$

$$\lambda^2<\text{tan.}^2\frac{2k+2}{n}\cdot 90°.$$

Thus, an indefinite number of values of λ^2 may be found that will make the polynome negative.

Having assumed such a value of λ^2, let any positive number whatever be substituted for s, and N will be converted into a rational function of α; the greatest power of α, or α^{2n-1}, being odd, and having a negative co-efficient; and the term which does not contain α being positive. Wherefore at least one positive value of α may be found that will satisfy the equation $\text{N}=0$; and, as has already been observed, this value of α will be such as to make $\lambda^2\alpha^2-s$ a positive quantity. It is possible indeed that, in the equation $\text{N}=0$, there may be several values of α for every assumed value of s; but we here confine our attention to the least positive value, which is distinguished by this circumstance, that it vanishes with the absolute term of the equation, or with s; whereas, when s is equal to zero, all the other roots of the equation $\text{N}=0$ have finite values depending upon the given co-efficients.

Now, if we suppose s to increase from zero to infinity, and assume two values, s, and $s+\delta s$, very near one another, according to what has been proved, we shall have the corresponding values α and $\alpha+\delta\alpha$, such, that the equation $\text{N}=0$ will be satisfied by substituting both s and α, and likewise $s+\delta s$ and $\alpha+\delta\alpha$. Hence, because $\text{N}=0$, and $\delta\text{N}=0$, we get

$$\frac{d\text{N}}{d\alpha}.\delta\alpha+\frac{d\text{N}}{ds}.\delta s=0,$$

$$\text{and, }\delta\alpha=-\frac{\delta s}{\left(\frac{d\text{N}}{d\alpha}\right)}\times\frac{d\text{N}}{ds}.$$

Again, if we substitute first s and α, and then $s+\delta s$ and $\alpha+\delta\alpha$, in the function M, we shall get

$$\delta\text{M}=\frac{d\text{M}}{d\alpha}.\delta\alpha+\frac{d\text{M}}{ds}.\delta s.$$

But, by comparing the functions M and N, the following properties will readily be discovered, viz.

$$\frac{d\text{M}}{d\alpha}+2\lambda^2\alpha.\frac{d\text{M}}{ds}=\text{N}-2\frac{d\text{N}}{ds}(\lambda^2\alpha^2-s),$$

$$\frac{d\text{M}}{ds}=\frac{1}{2}\cdot\frac{d\text{N}}{d\alpha}+\lambda^2\alpha\cdot\frac{d\text{N}}{ds}:$$

whence,

$$\frac{d\text{M}}{d\alpha}=\text{N}-2\frac{d\text{N}}{ds}(\lambda^2\alpha^2-s)-\frac{d\text{N}}{d\alpha}\lambda^2\alpha-2\lambda^4\alpha^2\frac{d\text{N}}{ds}.$$

Consequently,

$$\delta\text{M}=\left\{\text{N}-2\frac{d\text{N}}{ds}(\lambda^2\alpha^2-s)-\frac{d\text{N}}{d\alpha}\lambda^2\alpha-2\lambda^4\alpha^2\cdot\frac{d\text{N}}{ds}\right\}\times\delta\alpha+\left\{\frac{1}{2}\cdot\frac{d\text{N}}{d\alpha}+\lambda^2\alpha\cdot\frac{d\text{N}}{ds}\right\}\cdot\delta s:$$

and, if we observe that $\text{N}=0$, and substitute the value of $\delta\alpha$ found above, we shall get

$$\delta\text{M}=\frac{-\delta s}{\left(\frac{d\text{N}}{d\alpha}\right)}\cdot-\left\{2\left(\frac{d\text{N}}{ds}\right)^2(\lambda^2\alpha^2-s)+\frac{1}{2}\left(\frac{d\text{N}}{d\alpha}+2\lambda^2\alpha\frac{d\text{N}}{ds}\right)^2\right\},$$

in which expression all the quantities are essentially positive, except $\frac{d\text{N}}{d\alpha}$, which is always negative, as may be thus proved.

The quantity s remaining invariable, if we make $\alpha=0$, the function N will be positive; for it is equal to

$$\text{A}^{(3)}s+\text{A}^{(5)}s^2+\text{A}^{(7)}s^3+,\&c.;$$

and the same function will continue positive, while α increases from zero to the least root of the equation $\text{N}=0$. At this limit N is first equal to zero, and then becomes negative; it must, therefore, be decreasing, and consequently $\frac{d\text{N}}{d\alpha}$ is negative. It may indeed happen, that, for particular values of s, the co-efficients of N may be such, that N and $\frac{d\text{N}}{d\alpha}$ shall be both equal to zero at the same time; but, in such cases, it will readily appear that $\frac{d\text{N}}{ds}$ and δM will likewise be equal to zero. Wherefore δM will be negative; at least, if it become equal to zero for any particular values of s and α, it cannot become positive. It follows, therefore, that the function M itself will be invariably negative, while s and α increase together from zero to be infinitely great.

Now assume a series of values of s increasing from zero without limit, viz.

$$0,\,s^{(1)},\,s^{(2)},\,s^{(3)},\,\ldots\ldots\,s^{(x)},\,s^{(x+1)}\ldots.$$

and having substituted these in the function N, find, by means of the equation $\text{N}=0$, the corresponding values of α, viz.

$$0,\,\alpha^{(1)},\,\alpha^{(2)},\,\alpha^{(3)},\,\ldots\ldots\,\alpha^{(x)},\,\alpha^{(x+1)}\ldots$$

then, by substituting these values in M, we shall obtain a series of results all negative, and increasing from zero without limit, viz.

$$0,-\text{M}^{(1)},-\text{M}^{(2)},-\text{M}^{(3)}..-\text{M}^{(x)},-\text{M}^{(x+1)}..$$

and whatever be the magnitude of the positive quantity y, it must be contained between two consecutive terms of this last series, viz. between $M^{(x)}$ and $M^{(x+1)}$. But as the values of s may be assumed as near one another as we please, it follows that $M^{(x)}$ and $M^{(x+1)}$ may be made to approach to one another and to y, within any required degree of accuracy. Thus two values of s and α may be found that will satisfy both the equations,

$$y + M = 0,$$
$$N = 0;$$

and having found these values, we shall obtain the quadratic divisor of the proposed polynome $y + \varphi(u)$, viz. $(u - \alpha)^2 + \tau^2$, or

$$(u - \alpha)^2 + \lambda^2\alpha^2 - s.$$

In the preceding demonstration it is supposed that M increases without limit, as s becomes indefinitely great; which may be thus proved: The values of M and N will coincide nearly with the terms containing the highest powers of s and α, when these quantities are very great; and ultimately the functions may be considered as equal to those terms alone. In such circumstances, therefore, the values of the functions will be found by writing α^{2n} for $\varphi(\alpha)$; whence we get

$$M = \alpha^{2n} - 2n \, . \, \frac{2n - 1}{2} \, . \, \alpha^{2n-2} \, (\lambda^2\alpha^2 - s) +, \&c.$$

$$N = 2n\,\alpha^{2n-1} - 2n \, . \, \frac{2n - 1 \cdot 2n - 2}{2 \quad . \quad 3} (\lambda^2\alpha^2 - s) +, \&c.$$

and if we put $\lambda^2\alpha^2 - s = t^2\alpha^2$, or $\alpha^2 = \dfrac{s}{\lambda^2 - t^2}$,

then $M = \alpha^{2n} \left\{ 1 - 2n \, . \, \dfrac{2n - 1}{2} \, . \, t^2 +, \&c. \right\}$

$$N = \alpha^{2n-1} \left\{ 2n - 2n \, . \, \frac{2n - 1 \cdot 2n - 2}{2 \quad . \quad 3} \, . \, t^2 +, \&c. \right\}$$

Now, s remaining invariable, α will increase as t^2 increases; and the least value of α that will satisfy the equation $N = 0$, corresponds to the least value of t^2 that will make the polynome in the expression of N equal to zero; which value, according to what was before shown, is

$$t^2 = \tan.^2 \frac{1}{n} \times 90°.$$

But, if we put $t = \tan.\ \varphi$, we shall get

$$M = \alpha^{2n} \times \frac{\cos.\ 2n\varphi}{\cos.^{2n} \varphi};$$

or, because $\varphi = \dfrac{1}{n} \times 90°$; $\cos.\ \varphi = \dfrac{1}{\sqrt{1 + t^2}}$,

and $\alpha^2 = \dfrac{s}{\lambda^2 - t^2}$;

$$M = - s^n \times \left(\frac{1 + t^2}{\lambda^2 - t^2} \right)^n;$$

which proves the point assumed in the demonstration.

By a similar mode of reasoning, we may likewise prove the former case of the proposition, when y is negative. In this case the quadratic divisor is $(u - \alpha)^2 - \tau^2$; and if we proceed as before, or, which is the same thing, if we change the signs of y and τ^2 in the equations (C) already obtained, and put

$$M = \varphi(\alpha) + \frac{1}{2} \cdot \frac{d^2\varphi(\alpha)}{d\alpha^2} \cdot \tau^2 +, \&c.$$

$$N = \frac{d\varphi(\alpha)}{d\alpha} + \frac{1}{6} \cdot \frac{d^3\varphi(\alpha)}{d\alpha^3} \tau^2 +, \&c.;$$

we shall get

$$- y + M = 0.$$
$$N = 0.$$

Now, by pursuing the steps of the foregoing analysis, we may prove, first, that, for every assumed value of τ^2, a negative value of α may be found, which will satisfy the equation $N = 0$; and, secondly, that when the values which satisfy the equation $N = 0$ are substituted in the function M, the results will be invariably positive; whence it follows that a positive value of τ^2, and a negative value of α, may be found that will satisfy both the equations, whatever be the magnitude of y. The analogy between the two cases is thus placed in a strong light; and a little reflection will even bring us to this conclusion, that in reality the one case is a necessary consequence of the other. For since α and τ^2 depend only upon y, and the given co-efficients of the polynome, they will be functions of y; wherefore, in the equations of the first case, viz.

$$- y + M = 0,$$
$$N = 0,$$

α being negative, and τ^2 positive, we may suppose $-\alpha = y\varphi(y)$ and $\tau^2 = y\,\Psi(y)$, these values being such as to render each of the equations identical; and then the quadratic divisor $(u - \alpha)^2 - \tau^2$ will become

$$\left\{ u + y\,\varphi(y) \right\}^2 - y\Psi(y).$$

But, because the foregoing equations become identical by the substitution of the values mentioned, it is a necessary consequence that the equations of the second case, viz.

$$y + M = 0,$$
$$N = 0,$$

in which the signs of y, α, and τ^2, are contrary to what they were in the former equations, will likewise be identical, when $-\alpha = -y\varphi(-y)$ and $\tau^2 = -y\Psi(-y)$; and the quadratic divisor, $(u - \alpha)^2 - \tau^2$, will now become

$$\left\{ u - y\varphi(-y) \right\}^2 + y\Psi(-y).$$

Thus, when the quadratic divisor of the first case is expressed in terms of y, we have only to change the sign of that quantity, in order to have the quadratic divisor of the second case. It is not difficult to perceive, that what has now been proved is nothing more than another application of the principle employed in Sect. 10: a principle which is the real foundation of the imaginary arithmetic, with the processes of which the preceding investigations are intimately connected. None but real quantities have occurred in the analysis we have pursued, because we have sought to investigate τ^2, which is always rational; whereas, if we had proposed to find τ, we should inevitably have been led to the real quantity $\sqrt{y}$ in the one case, and to the impossible quantity $\sqrt{-y}$ in the other. These few observations are made for the purpose of throwing light upon a part of analysis which is certainly obscure in its principles, although there is no question that it is a useful, and even a necessary branch of the art of calculation. A fuller elucidation of the subject would be unsuitable to this place; but enough has been said to show that we must seek in the principles of analysis itself for the explanation of the operations it employs; and we may with great probability conclude that no satisfactory account of the imaginary calculus will ever be obtained by having recourse to fanciful geometrical constructions, or to the analogy between the circle and the hyperbola, or to the metaphysical proposition, that all processes with general symbols, whether significant or not, are equally entitled to be considered as demonstrative.

13. Having now proved, in a rigorous manner, that every polynome of even dimensions has at least one quadratic divisor of the one kind or the other, it follows that it may be reduced by division to another polynome two degrees lower: in like manner, this last polynome will admit of being lowered two degrees more; and by repeating the same process, the first polynome will at length be completely exhausted by quadratic divisors. If, therefore, we recollect, that every polynome of odd dimensions has one binomial divisor, we shall arrive at this general conclusion, " That every rational polynome can be completely exhausted by binomial and trinomial divisors; and, consequently, that it is equal to the product of a certain number of factors of the two first degrees."

It appears also that the binomial factors of any polynome are such only as arise from the resolution of the quadratic divisors; and they are, therefore, either real or imaginary. And thus we finally obtain the following proposition, which was assumed by Harriot, and is the foundation of the received theory of equations, namely, " Every rational polynome has as many binominal factors, and as many roots, real and imaginary, as it has dimensions."

The necessity of confirming, by a general demonstration, the assumed theory of the impossible roots of equations, was early felt; and accordingly, this point has engaged the attention of all the great mathematicians to whom analysis is indebted for the progress it has made in the course of the last and the present centuries. An account of their several researches would greatly exceed the limits of this article; but the reader will find all the information he can wish for in two long notes (9 and 10) of the *Traité des Equations Numeriques*, by La Grange, in which the author, with his usual elegance, has explained and commented upon the various modes of investigation that have been proposed. It will be sufficient to observe here, that all the demonstrations that have appeared are either calculations with impossible quantities, or they proceed upon the assumption that every equation has as many roots as dimensions, and thus involve the very thing to be proved.

14. The general cases in which mathematicians have been successful in resolving rational functions into their trinomial factors, are confined to the theorem of Cotes, and to a more general proposition of a similar kind, for which we are indebted to De Moivre. These instances are of great importance in analysis, and we shall therefore subjoin an investigation of them, because they are deduced in a very direct manner from the method we have followed.

Suppose, as before, that $f(x)$, or $x^n + A^{(1)}x^{n-1} + A^{(2)}x^{n-2} \ldots + A^{(n-1)}x + A^{(n)}$, is a rational polynome of n dimensions, and $(x-\alpha)^2+\tau^2$ one of its quadratic divisors; put $z = x - \alpha$, substitute $\alpha + z$ for x, and write the transformed function in two lines, one containing all the even, and the other all the odd powers of z; then the polynome will be equal to

$$f(\alpha) + \frac{1}{2}\cdot\frac{d^2f(\alpha)}{d\alpha^2}z^2 + \frac{1}{24}\cdot\frac{d^4f(\alpha)}{d\alpha^4}z^4 -, \&c.$$

$$+ z \times \left\{ \frac{df(\alpha)}{d\alpha} + \frac{1}{6}\ \frac{d^3f(\alpha)}{d\alpha^3}z^2 + \frac{1}{120}\cdot\frac{d^5f(\alpha)}{d\alpha^5}z^4, \&c. \right\}$$

By the same substitution of z for $x - \alpha$, the divisor $(x-\alpha)^2 + \tau^2$ will become $z^2 + \tau^2$; and, as before, the conditions that $z^2 + \tau^2$ shall divide each of the foregoing lines, will be expressed by the following equations, viz.

$$0 = f(\alpha) - \frac{1}{2}\cdot\frac{d^2f(\alpha)}{d\alpha^2}\tau^2 + \frac{1}{24}\cdot\frac{d^4f(\alpha)}{d\alpha^4}\tau^4 -, \&c. \quad \text{(D)}$$

$$0 = \frac{df(\alpha)}{d\alpha} - \frac{1}{6}\cdot\frac{d^3f(\alpha)}{d\alpha^3}\tau^2 + \frac{1}{120}\cdot\frac{d^5f(\alpha)}{d\alpha^5}\tau^4 -, \&c.$$

In these formulæ substitute the expanded values of $f(\alpha), \frac{df(\alpha)}{d\alpha}$, &c.; and class together all the homogeneous terms of the same order, that is, all the terms in which the exponents of α and τ amount to the same sum, then we shall have

$$0 = \alpha_n - n.\frac{n-1}{2}\alpha^{n-2}\tau^2 +, \&c.$$

$$+ A^{(1)}.\left\{\alpha^{n-1} - n-1.\frac{n-2}{2}.\alpha^{n-3}\tau^2 +, \&c.\right\}$$

$$+ A^{(2)}.\left\{\alpha^{n-2} - n-2.\frac{n-3}{2}\alpha^{n-4}\tau^2 +, \&c.\right\}$$

$$\&c.$$

$$0 = n\alpha^{n-1} - n.\frac{n-1.n-2}{2\ .\ 3}\alpha^{n-3}\tau^2 +, \&c.$$

$$+ A^{(1)}.\left\{(n-1)\alpha^{n-2} - n-1.\frac{n-2.n-3}{2\ .\ 3}\alpha^{n-4}\tau^2 +, \&c.\right\}$$

$$+ A^{(2)}.\left\{(n-2)\alpha^{n-3} - n-2.\frac{n-3.n-4}{2\ .\ 3}\alpha^{n-5}\tau^2 +, \&c.\right\}$$

$$\&c.$$

Now, put $\alpha = r \cos.\varphi$, $\tau = r \sin.\varphi$; and, by what was proved in Sect. 10, the two foregoing equations will become

$$r^n \cos.n\varphi + A^{(1)}r^{n-1}\cos.(n-1)\varphi \ldots\ldots + A^{(n-1)}r\cos.\varphi$$

$$+ A^{(n)} = 0, \quad \text{(E)}$$

$$\frac{1}{\sin.\varphi}.\left\{ r^{n-1}\sin.n\varphi + A^{(1)}r^{n-2}\sin.(n-1)\varphi \ldots\ldots \right.$$

$$\left. + A^{(n-)}\sin.\varphi \right\} = 0:$$

And the quadratic divisor $(x-\alpha)^2 + \tau^2$ will be changed into

$$x^2 - 2r\cos.\varphi.x + r^2.$$

When $\sin.\varphi = 0$, and $\varphi = 0$ or 180°, the preceding equations coincide with these, viz.

$$r^n \pm A^{(1)}r^{n-1} + A^{(2)}r^{n-2} \pm, \&c. = 0$$

$$nr^{n-1} \pm (n-1)A^{(1)}r^{n-2} + (n-2)A^{(2)}r^{n-3} \pm, \&c. = 0,$$

which express the condition that the given polynome has two or more factors equal to $x \mp r$; at which limits a quadratic divisor changes from being of the form $(x-\alpha)^2 - \tau^2$ to be of the form $(x-\alpha)^2 + \tau^2$, or the contrary. Thus we learn that, in the equations (E), $\sin.\varphi$ must always have a finite value, and then the denominator of the second equation may be neglected.

Let the preceding investigation be applied to find the quadratic factors of $x^n - a^n$. In this case the two equations (E) will become

$$r^n \cos.n\varphi - a^n = 0$$

$$r^{n-1} \times \frac{\sin. n\varphi}{\sin. \varphi} = 0;$$

whence

$$r = a,$$
$$\cos. n\varphi = 1,$$
$$\frac{\sin. n\varphi}{\sin. \varphi} = 0.$$

Now, excluding the cases when $\varphi = 0$ and $\varphi = 180°$, the last equation will be satisfied when $\varphi = \frac{2k+1}{n} \times 180°$, or $\varphi = \frac{2k}{n} \times 180°$, the numerators of the fractions representing all the odd and even numbers less than the common denominator; but the second equation will be satisfied only when $\varphi = \frac{2k}{n} \times 180°$; wherefore all the quadratic factors of the function $x^n - a^n$ will be comprehended in the formula

$$x^2 - 2ax \times \cos. \frac{2k}{n} \times 180° + a^2.$$

When n is an even number, the quadratic factors will amount to $\frac{n-2}{2}$; and if to them we add the simple factors $x + a$ and $x - a$, we shall have the complete resolution of the function. When n is odd, the number of quadratic factors is $\frac{n-1}{2}$, to which must be added the binomial factor $x - a$.

By proceeding in a similar manner in the case of the function $x^n + a^n$, we shall have the equations

$$r = a,$$
$$\cos. n\varphi = -1,$$
$$\frac{\sin. n\varphi}{\sin. \varphi} = 0.$$

Excluding the cases when $\varphi = 0$ and $\varphi = 180°$, the second and third equations will be both satisfied, when $\varphi = \frac{2k+1}{n} \times 180°$, the numerator of the fraction representing any odd number less than n. Wherefore all the quadratic factors will be comprehended in the formula

$$x^2 - 2ax \times \cos. \frac{2k+1}{n} \times 180° + a^2.$$

When n is even, the number of quadratic factors is $\frac{n}{2}$, and they exhibit the complete resolution of the function. When n is odd, the number of quadratic factors is $\frac{n-1}{2}$, to which the binomial factor $x + a$ must be added.

Let us next take the more general function.

$$x^{2n} - 2\beta x^n a^n + a^{2n}.$$

And, in the first place, when β is greater than unit, the function is equal to

$$\left\{x^n - a^n(\beta + \sqrt{\beta^2 - 1})\right\} \times \left\{x^n - a^n(\beta - \sqrt{\beta^2 - 1})\right\};$$

and the quadratic factors may be found by the cases already considered.

When β is less than unit, let $\beta = \cos. \theta$, and the function to be resolved will be

$$x^{2n} - 2a^n x^n \cos. \theta + a^{2n}.$$

By means of the equations (E) we get

$$r^{2n} \cos. 2n\varphi - 2a^n r^n \cos. \theta \cos. n\varphi + a^{2n} = 0,$$
$$r^{2n-1} \times \frac{\sin. 2n\varphi}{\sin. \varphi} - 2a^n r^{n-1} \times \frac{\sin. n\varphi}{\sin. \varphi} \times \cos. \theta = 0;$$

and hence

$$r = a,$$
$$\cos. 2n\varphi - 2 \cos. \theta \cos. n\varphi + 1 = 0,$$
$$\frac{\sin. 2n\varphi}{\sin. \varphi} - 2 \frac{\sin. n\varphi}{\sin. \varphi} \times \cos. \theta = 0.$$

But, $\cos. 2n\varphi + 1 = 2 \cos.^2 n\varphi$; and $\sin. 2n\varphi = 2 \cos. n\varphi \times \sin. n\varphi$; wherefore the two last equations will become

$$2 \cos. n\varphi (\cos. n\varphi - \cos. \theta) = 0,$$
$$2 \frac{\sin. n\varphi}{\sin. \varphi} (\cos. n\varphi - \cos. \theta) = 0:$$

and these, supposing $\cos. \theta$ different from unit, can be satisfied only by making $\cos. n\varphi - \cos. \theta = 0$, or

$$\cos. n\varphi = \cos. \theta.$$

Now, $\cos. \theta = \cos. (m \times 360° + \theta)$, m being any integer number whatever, zero included; and hence $\varphi = \frac{m \times 360° + \theta}{n}$, which formula comprehends all the values of θ that will satisfy the above equations. Wherefore all the factors sought will be contained in this general expression, viz.

$$x^2 - 2ax \cos. \frac{m \times 360° + \theta}{n} + a^2;$$

in which, if for m we substitute all the integer numbers less than n, zero included, we shall obtain the n quadratic factors of the proposed function.

15. The quadratic divisors $(x - \alpha)^2 - r^2$ and $(x - \alpha)^2 + r^2$, have hitherto been considered separately; but they may be both represented by $(x - \alpha)^2 - s$, which will coincide with the one or the other, according as s is positive or negative. And, if we now proceed as before, we shall get the following equations, which express the conditions necessary, in order that the polynome $f(x)$ of any proposed dimensions, as n, shall be divisible by $(x - \alpha)^2 - s$, viz.

$$0 = f(\alpha) + \frac{1}{2} \cdot \frac{d^2 f(\alpha)}{d\alpha^2} s + \frac{1}{24} \cdot \frac{d^4 f(\alpha)}{d\alpha^4} \cdot s^2 +, \&c.$$
$$0 = \frac{df(\alpha)}{d\alpha} + \frac{1}{6} \cdot \frac{d^3 f(\alpha)}{d\alpha^3} \cdot s + \frac{1}{120} \cdot \frac{d^5 f(\alpha)}{d\alpha^5} s^2 +, \&c.$$

By eliminating s we shall obtain an equation, viz.

$$A = 0,$$

in which α is the unknown quantity. As the process of elimination is independent of the particular values of the co-efficients of $f(x)$, the degree of the resulting equation will be the same when the polynome $f(x)$ has as many real roots as dimensions, and when the case is otherwise. But when $f(x)$ is equal to the product of n real binomial factors, the multiplication of every two of them will form a quadratic factor. The number of such factors will, therefore, be equal to $n \times \frac{n-1}{2}$, which expresses all the combinations made with n things taken two and two. Consequently, there will be just so many different values of α that will satisfy the equation $A = 0$, which will, therefore, have its exponent equal to $n \times \frac{n-1}{2}$. It thus appears that the equation $A = 0$ rises in its dimensions very rapidly above the given polynome, on which account little advantage is derived from this procedure.

Again, by eliminating α from the same two equations, we shall obtain one, viz.

$$S = 0,$$

in which s is the unknown quantity. This equation, which has already been alluded to (Sect. 8), rises to the same dimensions with the former equation, $A = 0$; but it is possessed of some useful properties, derived chiefly from the consideration that every positive root gives a quadratic factor of the form $(x - \alpha)^2 - \tau^2$ in the polynome $f(x)$, and every negative root a quadratic factor of the form $(x - \alpha)^2 + \tau^2$ in the same polynome.

The quadruple of s is equal to the square of the difference of the two binomial factors of $(x - \alpha)^2 - s$; whence it follows that the quadruples of the several roots of the equation $S = 0$ are equal to the squares of the differences of the roots of $f(x) = 0$. If, therefore, we put x', x'', x''', &c. for the roots of $f(x) = 0$, the roots of $S = 0$ will be

$$\frac{1}{4}(x' - x'')^2,\ \frac{1}{4}(x' - x''')^2,\ \frac{1}{4}(x'' - x''')^2,\ \text{\&c.};$$

and from this it is manifest that the co-efficients of the same equation will be known symmetrical functions of the quantities x', x'', x''', &c. or of the roots of $f(x) = 0$. The rules formerly explained may, therefore, be employed for calculating the co-efficients of $S = 0$; and this method of forming the equation is not only more convenient than the process of eliminating, but it likewise has the advantage of enabling us to find any one co-efficient separately without computing the rest. Thus, if we put

$$K^{(n)} = (x' - x'')^2 \cdot (x' - x''')^2 \cdot (x'' - x''')^2 \cdot \text{\&c.}$$

and expand this product, and in place of the symmetrical functions of which it is composed, substitute their values in terms of the given co-efficients of $f(x) = 0$, we shall obtain the value of $K^{(n)}$; and the last term of the equation $S = 0$ will be equal to

$$\pm \frac{K^{(n)}}{2^{n(n-1)}}$$

the upper sign taking place when $n \times \frac{n-1}{2}$, the dimensions of the equation $S = 0$ is even, and the lower sign when the same number is odd.

If we suppose the given equation $f(x) = 0$ to be possessed of as many real roots as dimensions, or to have n real binomial factors, the product of every two of these will be a quadratic factor $(x - \alpha)^2 - s$, in which s is positive; wherefore, the roots of $S = 0$ will be all real and all positive. On the other hand, when the given equation $f(x) = 0$ has not as many real roots as dimensions, it will be divisible by one or more quadratic factors not resolvable into real binomial factors, and in which s is negative; consequently, the equation $S = 0$ will have one or more negative roots. It is, therefore, a property of the auxiliary equation $S = 0$, that when the roots are all real they are all positive, and when they are not all real some of them are negative. Now the rule of Descartes will enable us to find whether the roots are all positive or not; and by this means we shall discover whether the roots of the given equation $f(x) = 0$ are all real or not. From what has been said, we may lay down this rule: "The proposed equation $f(x) = 0$ will have all its roots real when the auxiliary equation $S = 0$ has as many variations from one sign to another as it has dimensions, or when its terms are alternately positive and negative; otherwise the proposed equation will have one or more quadratic factors of the form $(x - \alpha)^2 + \tau^2$, but the number of such factors cannot exceed the continuations of the same sign in the auxiliary equation."

Again, in the equation $S = 0$, the polynome S is equal to a certain number of binomial factors of the forms $x - a$ and $x + a$, multiplied into a supplementary polynome of even dimensions, which, not being capable of having a negative value, will have its last term positive (Sect. 5). It is manifest, therefore, that the last term of $S = 0$ will be positive or negative, according as the number of factors of the form $x - a$ is even or odd, that is, according as the equation has an even or odd number of real and positive roots. But every two real roots in the equation $f(x) = 0$ give one real and positive root in the subsidiary equation $S = 0$; wherefore, if m denote the number of real roots in the former equation, the number of real and positive roots in the latter will be equal to $m \times \frac{m-1}{2}$; and the last term of the subsidiary equation will be positive or negative, according as $m \times \frac{m-1}{2}$ is an even or an odd number.

In a cubic equation $x^3 + px + q = 0$, m is either one or three. In the first case, the equation $S = 0$ will have no positive roots, and the last term will be positive; in the second case, it will have three real and positive roots, and the last term will be negative. Now the dimensions of $S = 0$ being odd, the function $K^{(3)}$ will be negative in the first case and positive in the second. Wherefore the given cubic equation will have one real root, or three, according as the function $K^{(3)}$, that is,

$$(x' - x'')^2 \cdot (x' - x''')^2 \cdot (x'' - x''')^2,$$

or $-4p^3 - 27q^2$, is negative or positive.

In a biquadratic equation $x^4 + px^2 + qx + r = 0$, m is equal to zero, or two, or four. In the first case the equation $S = 0$ has no positive roots, in the third it has six, and in both cases the last term is positive. In the second case the same equation has only one real and positive root, and the last term is negative. The dimensions of $S = 0$, equal to $\frac{4 \times 3}{2}$, being even, the function $K^{(4)}$ will be positive in the first and third cases, and negative in the second case. Wherefore the proposed biquadratic equation will have only two real roots when the function $K^{(4)}$, that is,

$(x' - x'')^2 \cdot (x' - x''')^2 \cdot (x' - x^{\mathrm{IV}})^2 \cdot (x'' - x''')^2 \cdot (x - x^{\mathrm{IV}})^2 \cdot (x''' - x^{\mathrm{IV}})^2$, or, $256r^3 - 128p^2r^2 + 144q^2pr + 16p^4r - 27q^4 - 4q^2p^3$, is negative; and when the same function is positive, the proposed equation will have four real roots, if the terms of the auxiliary equation $S = 0$ be alternately positive and negative; otherwise it will have no real roots.

In an equation of the fifth degree, m is equal to one, or three, or five. In the first and third cases the last term of $S = 0$ will be positive, for there are either no positive roots or ten; in the second case the last term is negative, the number of positive roots being three. The dimensions of $S = 0$, equal to $\frac{5 \times 4}{2}$, being even, the function $K^{(5)}$ will be positive in the first and third cases, and negative in the second. Wherefore the given equation of the fifth degree will have three real roots when the function $K^{(5)}$ is negative; and when the same function is positive, it will have five real roots if the terms of the auxiliary equation $S = 0$ be alternately positive and negative; otherwise it will have but one.

Resolution of Algebraic Equations.

16. When the co-efficients of an equation are given in

numbers, we may investigate the numerical value of any one root separately, by first seeking the limits between which it lies, and then narrowing those limits to any required degree of approximation. But this process is not what is meant by the general solution of algebraical equations, which supposes that the co-efficients are denoted by general symbols, and consists in finding such a function of those quantities as shall, by the multiplicity of its values, represent all the roots. An algebraical expression is susceptible of many values, by means of the different radical quantities it contains; but these radical quantities being themselves the roots of an equation, it follows that the general formula for the solution of any proposed equation can be nothing more than a function of the given co-efficients combined with the roots of another equation.

The solution of quadratic equations has been known since the origin of algebra; it is found in the work of Diophantus, the first treatise on the science extant, if it be not the very first that was written. The Italian mathematicians, who are the founders of the modern algebra, discovered the solution of cubic and biquadratic equations. The rules they invented for this purpose are, however, rather the result of particular artifices than deductions from any profound views of the structure of the equations they considered. In the course of the last and the present centuries, the general solution of equations has been the subject of almost innumerable researches by all the mathematicians of the first rank; but their labours have not been successful in advancing this branch of the science beyond the steps made by the first algebraists.

The rules usually given for the solution of cubic and biquadratic equations are to be found in all the elementary books, and it would be superfluous to repeat them here. An account of the attempts that have been made to obtain a general theory for solving algebraic equations would greatly exceed the limits we must prescribe to ourselves. What has most impeded the progress of algebraists in their researches on this subject, is the difficulty of treating it by a perfect analysis, or of arriving at general conclusions by a process of reasoning founded solely on the principles of the inquiry, and disengaged from particular artifices of calculation, and from particular suppositions. In what follows, we shall endeavour to lay before our readers the general principles on which is founded all that has been successfully accomplished in this theory.

Let the three roots of a cubic equation be represented by a, b, c; and having interchanged these letters among one another, in all possible ways, we shall get the six permutations following, viz.

$$\begin{array}{lll} abc, & cab, & bca, \\ acb, & bac, & cba. \end{array}$$

The combinations that stand first on the left are formed by prefixing the same letter to the permutations made with the other two; and those on each line are derived from one another by making the last letter of one stand first in that which follows, while the other two letters preserve the same order.

Now let $\varrho^3 - 1 = 0$; and let the letters of first combination of each line be prefixed in order to the three terms of $1 + \varrho + \varrho^2$; then we shall get

$$t = a + b\varrho + c\varrho^2, \qquad s = a + c\varrho + b\varrho^2;$$

and if we multiply t and s by $1, \varrho, \varrho^2$ successively, we shall further obtain

$$\begin{array}{ll} t = a + b\varrho + c\varrho^2, & s = a + c\varrho + b\varrho^2, \\ t\varrho = c + a\varrho + b\varrho^2, & s\varrho = b + a\varrho + c\varrho^2, \\ t\varrho^2 = b + c\varrho + a\varrho^2. & s\varrho^2 = c + b\varrho + a\varrho^2. \end{array}$$

The six quantities t, $t\varrho$, $t\varrho^2$, s, $s\varrho$, $s\varrho^2$, comprehend all the values that can be formed by combining with $1 + \varrho + \varrho^2$, the three letters taken in any order whatever; and it is obvious that the cubes of all these six quantities, being each equal either to t^3 or s^3, have no more than two values.

And because t^3 and s^3 have only one value each, any symmetrical functions of them, as $t^3 + s^3$ and $t^3 s^3$, will have determinate values, which remain the same, however the letters a, b, c be interchanged among one another. The quantities $t^3 + s^3$ and $t^3 s^3$ must, therefore, be symmetrical functions of a, b, c; and, consequently, they can be found in terms of the co-efficients of the given equation.

By actually involving to the third power, we get

$$\begin{aligned} t^3 = a^3 + b^3 + c^3 + 6\,abc \\ + 3\,(a^2b + b^2c + c^2a)\,.\,\varrho \\ + 3\,(a^2c + c^2b + b^2a)\,.\,\varrho^2, \\ s^3 = a^3 + b^3 + c^3 + 6\,abc \\ + 3\,(a^2c + c^2b + b^2a)\,.\,\varrho \\ + 3\,(a^2b + b^2c + c^2a)\,.\,\varrho^2. \end{aligned}$$

and likewise

$$\begin{aligned} (a + b + c)^3 = a^3 + b^3 + c^3 + 6\,abc \\ + 3\,(a^2b + b^2c + c^2a) \\ + 3\,(a^2c + c^2b + b^2a). \end{aligned}$$

Now $1 + \varrho + \varrho^2 = 0$, when ϱ is any root of $\varrho^3 - 1 = 0$ different from unit; therefore, by adding the last three expressions, we get

$$\begin{aligned} t^3 + s^3 = 3\,(a^3 + b^3 + c^3) + 18\,abc \\ - (a + b + c)^3. \end{aligned}$$

Again, by actually multiplying

$$\begin{aligned} ts = a^2 + b^2 + c^2 \\ + (ab + bc + ca)\,.\,\varrho \\ + (ab + bc + ca)\,.\,\varrho^2; \end{aligned}$$

and, because $\varrho + \varrho^2 = -1$,

$$\begin{aligned} ts = a^2 + b^2 + c^2 \\ - (ab + bc + ca). \end{aligned}$$

By means of the preceding formulæ, we can compute the values of $t^3 + s^3$ and $t^3 s^3$; and these values being the co-efficients of a quadratic equation having its roots equal to t^3 and s^3, we can thence find t^3 and s^3, and t and s. Now t and s being known, we have

$$\begin{aligned} a + b + c &= a + b + c, \\ t &= a + b\varrho + c\varrho^2, \\ s &= a + c\varrho + b\varrho^2; \end{aligned}$$

wherefore,

$$a = \frac{1}{3}(a + b + c) + \frac{1}{3}(t + s),$$

$$b = \frac{1}{3}(a + b + c) + \frac{1}{3}(t\varrho^2 + s\varrho),$$

$$c = \frac{1}{3}(a + b + c) + \frac{1}{3}(t\varrho + s\varrho^2).$$

To apply the foregoing investigation, we shall take a cubic equation, $x^3 - 3px - 2q = \upsilon$, which is so prepared as to want the second term, then (Sect. 9)

$$\begin{aligned} a + b + c &= 0, \\ ab + ac + bc &= -3p, \\ a^2 + b^2 + c^2 &= 6p, \\ a^3 + b^3 + c^3 &= 6q, \\ abc &= 2q; \end{aligned}$$

consequently $t^3 + s^3 = 3^3 \times 2q$; $ts = 9p$, and $t^3 s^3 = 3^3 \times 3^3\,.\,p^3$. Hence

$$\frac{1}{3}t = (q + \sqrt{q^2 - p^3})^{\frac{1}{3}},$$

$$\frac{1}{3}s = (q - \sqrt{q^2 - p^3})^{\frac{1}{3}},$$

Wherefore, by substituting these values in the expressions of the roots, we get

$$a = (q + \sqrt{q^2 - p^3})^{\frac{1}{3}} + (q - \sqrt{q^2 - p^3})^{\frac{1}{3}},$$

$$b = \varrho^2 \cdot (q + \sqrt{q^2 - p^3})^{\frac{1}{3}} + \varrho\,.\,(q - \sqrt{q^2 - p^3})^{\frac{1}{3}},$$

$$c = \varrho \cdot (q + \sqrt{q^2 - p^3})^{\frac{1}{3}} + \varrho^2 \cdot (q - \sqrt{q^2 - p^3})^{\frac{1}{3}}.$$

The preceding investigation, as well as all other methods that have been proposed for cubic equations, leads to the same result with the rule invented by Cardan; and, like that rule, it becomes in some cases insufficient for arithmetical computation, on account of the imaginary quantities that appear in the expressions of the roots. What is now mentioned is not an accidental circumstance, but a necessary consequence of the method of investigation pursued, and of the introduction of the imaginary roots of the equation $\varrho^3 - 1 = 0$. When a, b, c, are real quantities, the value of t and s will be both imaginary, because they involve ϱ and ϱ^2, or $\frac{-1+\sqrt{-3}}{2}$ and $\frac{-1-\sqrt{-3}}{2}$. In this case, therefore, although the three roots of the proposed equation are all real, yet the algebraic expressions of them are all imaginary, and useless for the purpose of numerical calculation; and the former circumstance is precisely the reason of the latter. On the other hand, when one root a is real and the other two imaginary, the impossible quantities destroy one another in the expressions of t and s, which are, therefore, real quantities; and in this case the algebraic formulæ answer for finding the numerical values of the roots. The distinction here pointed out depends on the radical $\sqrt{q^2 - p^3}$, which is real or imaginary, according as the equation has one or three real roots, because $q^2 - p^3$ is always positive in the first case and negative in the second.

Much labour and thought have been bestowed in order to free the formulæ for the roots of cubic equations from the imaginary expressions that render them unfit for arithmetical computation. In particular instances the difficulty disappears; namely, when the radical quantities are perfect cubes, in which cases the impossible parts of the cube roots destroy one another, so as to leave none but real quantities in the expressions of the roots of the equation. And, by expanding the radical quantities, we may in all cases obtain the roots of a cubic equation in series of an infinite number of terms free from the imaginary sign. But when it is required to transform the formulæ for the case of a cubic equation with three real roots, into finite expressions free from impossible quantities, and to do so without employing any other than the received notations of algebra, all attempts to solve the problem have led to equations in the same circumstances with the one proposed, and have ended in bringing back the same difficulty; in so much that equations of the description mentioned are said to be in the irreducible case.

It is, however, possible to transform the formulæ for the roots of a cubic equation in the irreducible case into real expressions, although not so as to fulfil all the conditions above mentioned. Let $q^2 - p^3 = y^2$; then $p = (q^2 - y^2)^{\frac{1}{3}}$: wherefore the equation $x^3 - 3px - 2q = 0$, will become

$$x^3 - 3\,(q^2 - y^2)^{\frac{1}{3}}\,x - 2q = 0 \ldots (1).$$

By the preceding formula the value of x in this equation will be

$$x = (q + y)^{\frac{1}{3}} + (q - y)^{\frac{1}{3}};$$

or, according to the notation of Section 10, making

$$n = \frac{1}{3},$$

$$x = 2\mathrm{H}_{\frac{1}{3}}\,(q, y^2).$$

By substituting this value of x, we get

$$\left\{2\mathrm{H}_{\frac{1}{3}}(q, y^2)\right\}^3 - 3(q^2 - y^2)^{\frac{1}{3}} . \left\{2\mathrm{H}_{\frac{1}{3}}(q, y^2)\right\} - 2q = 0;$$

which equation, being true for all values of q and y^2, must be identical, or, when expanded, must consist of a series of quantities that mutually destroy one another. Now the equation will still be identical, when y^2 is changed into $-y^2$; so that we shall have

$$\left\{2\mathrm{H}_{\frac{1}{3}}(q, -y^2)\right\}^3 - 3(q^2 + y^2) . ^{\frac{1}{3}} \left\{2\mathrm{H}_{\frac{1}{3}}(q, -y^2)\right\} - 2q = 0;$$

and this proves that the equation

$$x^3 - 3\,(q^2 + y^2)^{\frac{1}{3}} . x - 2q = 0 \ldots (2)$$

is solved by the formula

$$x = 2\mathrm{H}_{\frac{1}{3}}\,(q, -y^2).$$

As the investigation in Section 10 is equally true, whether n be a whole or a fractional number, we may apply it to find the value of the symbol $2\mathrm{H}_{\frac{1}{3}}\,(q, -y^2)$.

For this purpose, let
$q = r \cos. \varphi = r \cos. (\varphi + 360°) = r \cos. (\varphi + 2 . 360°)$,
$y = r \sin. \varphi = r \sin. (\varphi + 360°) = r \sin. (\varphi + 2 . 360°)$;
then $r = \sqrt{q^2 + y^2}$; and, according as we take one or other of the angles that have the same sines and cosines, we shall obtain three different values of $2\mathrm{H}_{\frac{1}{3}}\,(q, -y^2)$, or of x, viz.:

$$a = 2r^{\frac{1}{3}} . \cos. \frac{\varphi}{3},$$

$$b = 2r^{\frac{1}{3}} . \cos. \left(\frac{\varphi}{3} + 120°\right),$$

$$c = 2r^{\frac{1}{3}} . \cos. \left(\frac{\varphi}{3} + 240°\right).$$

By putting $p = (q^2 + y^2)^{\frac{1}{3}}$, the equation (2) will assume the same form as at first, namely,

$$x^3 - 3px - 2q = 0;$$

and because $p^3 = q^2 + y^2 = r^2$, and $y = \sqrt{p^3 - q^2}$, if we determine the angles by means of their tangents instead of their sines and cosines, we shall get $\frac{\sqrt{p - q^2}}{q} = \tan. \varphi = \tan. (\varphi + 360°) = \tan. (\varphi + 2 . 360°)$; and the three roots of the equation will be

$$a = 2\sqrt{p} . \cos. . \frac{\varphi}{3},$$

$$b = 2\sqrt{p} . \cos. \left(\frac{\varphi}{3} + 120°\right),$$

$$c = 2\sqrt{p} . \cos. \left(\frac{\varphi}{3} + 240°\right).$$

Every cubic equation falls under one or other of the formulæ (1) and (2), except when $y = 0$, or $p^3 = q^2$, which takes place when an equation changes from one class to another; and in this case we have

$$x^3 - 3q^{\frac{2}{3}} . x - 2q = (x - 2\,q^{\frac{1}{3}}) . (x + q^{\frac{1}{3}}) . (x + q^{\frac{1}{3}}).$$

The several rules that have now been given, therefore, include every possible case.

The difficulty attending the irreducible case arises from a real distinction between the two subordinate classes of cubic equations, and is insurmountable by the ordinary operations of algebra. There is no permanent distinctions of equations belonging to the same order, when we consider their roots as positive or negative; because, in any proposed equation, all the roots, or as many of them as we please, can be changed from positive to negative, by the simple artifice of increasing or diminishing them all by a given quantity. But the case is otherwise when we consider the roots of an equation in their character of real or imaginary quantities. No transformation can change an equation with one real root into another with three real roots, without involving the operations of the impossible arithmetic. If, therefore, we lay down this condition, namely, that the formulæ for the roots of equations must be in a shape fit for numerical calculation, we may conclude that in fact there is no resolution of equations except what consists in reducing all those of the same class to some one of that class, the most simple and convenient in its form that can be found. If we examine the preceding investigation, it will appear that it is merely an attempt to reduce all cubic equations to the form $x^3 - A = 0$; and this readily succeeds without impossible operations, when the proposed equation, and that with which it is compared, have their roots of a similar description; and it as surely fails when the case is otherwise.

In geometry, where the relations of the magnitudes under consideration are never lost sight of, there is no tendency to refer the solution of a problem to a class to which it does not belong. The ancient geometer could never be in danger of applying the problem for finding two mean proportionals to a case that can be constructed only by the trisection of an angle. The modern analyst, dismissing the original magnitudes of his problem, and reducing all possible relations to equations in abstract numbers, is apt to overlook distinctions, and sometimes to waste his labour, in seeking to accomplish what a due separation of cases would show to be impossible. There is the same distinction between the class of cubic equations with one real root, and that with three real roots, that there is between the two geometrical problems alluded to above; and the algebraist who attempts, by means of the ordinary operations of his art, to transform Cardan's formula so as to make it apply to the irreducible case, is precisely in the same situation with the geometer who should set about trisecting an angle by finding two mean proportionals.

The power and force of the algebraic method does not consist in breaking down real distinctions, but in connecting, by sure and general principles, many truths which in geometry are joined only by vague analogies, and even have no affinity at all. This advantage is derived chiefly from the doctrine of negative quantities, and from the impossible arithmetic. By means of the first, a formula which is obtained by considering only one state of the data of a problem, applies, necessarily and by the very structure of analytical language, to the same problem in all possible conditions of the data. On the other hand, when the relations of the data vary, the geometer is obliged to subdivide his problem into cases, or into other subordinate problems; and although it may be perceived that great similitude prevails among all the subdivisions, yet it is impossible to reduce the analogy between them to determinate rules, as is done in algebra. But in the whole compass of geometry there is nothing that bears any resemblance to the imaginary arithmetic. When the geometer has fixed the *determination* of his problem, or ascertained the limits within which it is possible, he has drawn a line that must be the boundary of his investigation. Now it is to truths lying beyond this line that the meaning of the comprehensive expressions of the imaginary arithmetic must be referred. It is not to be understood that a problem can be solved by algebra, which is impossible in geometry; but the analytical formulæ, at the same time that they mark the limits of the problem, go beyond them, and point out connected truths, that require only certain changes to be made in the algebraic expressions, in like manner as all the possible cases of the same problem are derived from one only, by means of the variations of the signs.

Biquadratic equations.

If a, b, c, d, represent the four roots of a biquadratic equation; and if we prefix the same letter a to all the permutations made with the other three, we shall get the six combinations following, viz.

$$abcd,\quad adbc,\quad acdb,$$
$$adcb,\quad acbd,\quad abdc.$$

In the first line, the letters b, c, d, are made to circulate, by placing immediately after the immoveable letter a that which stands last in the combination preceding; and in the second line the moveable letters have respectively an inverted order to what they have in the first line.

Let $\varrho^2 - 1 = 0$; and let the four letters taken in the several orders of the six combinations be prefixed to the terms of $1 + \varrho + \varrho^2 + \varrho^3$; the results of the first line being t, t', t'', and those of the second line s, s', s''; then

$$\begin{aligned} t &= a + b\varrho + c\varrho^2 + d\varrho^3, & s &= a + d\varrho + c\varrho^2 + b\varrho^3, \\ t' &= a + d\varrho + b\varrho^2 + c\varrho^3, & s' &= a + c\varrho + b\varrho^2 + d\varrho^3, \\ t'' &= a + c\varrho + d\varrho^2 + b\varrho^3, & s'' &= a + b\varrho + d\varrho^2 + c\varrho^3. \end{aligned}$$

Now, in the equation $\varrho^2 - 1 = 0$, ϱ is either equal to $+1$ or to -1; and whether we take the one value or the other, it is apparent that $t = s$, $t' = s'$, $t'' = s''$.

Again, from every one of the six foregoing combinations, four others are derived by circulating the letters continually from the last place to the first; and in this manner we obtain twenty-four permutations, which are all that can be made with four letters. Thus, if we take $abcd$, and move the letters as directed, we shall get these four combinations, viz.

$$\begin{gathered} abcd, \\ dabc, \\ cdab, \\ bcda. \end{gathered}$$

And if we multiply t by ϱ continually, observing to retain the three first powers of ϱ, and to make $\varrho^4 = 1$, we shall get

$$\begin{aligned} t &= a + b\varrho + c\varrho^2 + d\varrho^3, \\ t\varrho &= d + a\varrho + b\varrho^2 + c\varrho^3, \\ t\varrho^2 &= c + d\varrho + a\varrho^2 + b\varrho^3, \\ t\varrho^3 &= b + c\varrho + d\varrho^2 + a\varrho^3; \end{aligned}$$

so that t, $t\varrho$, $t\varrho^2$, $t\varrho^3$, are the functions formed by prefixing to $1 + \varrho + \varrho^2 + \varrho^3$, the letters of the four combinations; and it is obvious that these functions have all the same square, equal to t^2.

Wherefore, if the four letters, taken in all possible orders, be prefixed to the terms of $1 + \varrho + \varrho^2 + \varrho^3$, the squares of the twenty-four resulting functions will be equal to one or other of the six quantities, t^2, t'^2, t''^2, s^2, s'^2, s''^2; and since it has been proved that $t = s$, $t' = s'$, $t'' = s''$, it follows that the twenty-four squares have no more than three different values, equal to t^2, t'^2, t''^2.

And because t^2, t'^2, t''^2, can have no more than one value each, any symmetrical functions of them, viz.

$$\begin{gathered} t^2 + t'^2 + t''^2, \\ t^2t'^2 + t^2t''^2 + t'^2t''^2, \\ t^2t'^2t''^2, \end{gathered}$$

will have determinate values independent of the order of the letters a, b, c, d. The same functions will therefore be symmetrical expressions of the roots of the given biquadratic equation, and they will be known in terms of the co-efficients of that equation.

Supposing $\varrho = -1$, we get

$$\begin{aligned} t &= a - b + c - d, \\ t' &= a - d + b - c, \\ t'' &= a - c + d - b; \end{aligned}$$

and hence

$$\begin{aligned} t^2 &= a^2 + b^2 + c^2 + d^2 \\ &\quad - 2(ab + ad + bc + cd) + 2(ac + bd), \\ &= (a + b + c + d)^2 - 4\Sigma . ab + 4(ac + bd) \cdot, \end{aligned}$$

the symbol $\Sigma\,.\,ab$ being used here, as in Sect. 9, to denote the sum of the products of every two of the roots. Wherefore, if we put

$$\begin{aligned} M &= (a+b+c+d)^2 - 4\Sigma\,.\,ab, \\ m &= ac+bd, \\ m' &= ab+dc, \\ m'' &= ad+bc, \end{aligned}$$

then

$$\begin{aligned} t^2 &= M+4m, \\ t'^2 &= M+4m', \\ t''^2 &= M+4m''; \end{aligned}$$

and hence

$$\begin{aligned} t^2+t'^2+t''^2 &= 3M+4(m+m'+m''), \\ t^2t'^2+t^2t''^2+t'^2t'''^2 &= 3M^2+\ 8M(m+m'+m'') \\ &\quad +16(mm'+mm''+m'm''). \end{aligned}$$

But it will readily appear that

$$\begin{aligned} m+m'+m'' &= \Sigma\,.\,ab \\ mm'+mm''+m'm'' &= (a+b+c+d)\times\Sigma\,.\,abc \\ &\quad - 4abcd. \end{aligned}$$

Now, by substituting these values, we get

$$\begin{aligned} t^2+t'^2+t''^2 &= 3(a+b+c+d)^2 - 8\Sigma\,.\,ab, \\ t^2t'^2+t^2t''^2+t'^2t''^2 &= 3(a+b+c+d)^4 - 16(a+b+c \\ &\quad +d)^2\times\Sigma\,.\,ab \\ &\quad +16(a+b+c+d)\times\Sigma\,.\,abc + 16(\Sigma\,.\,ab)^2 \\ &\quad - 64abcd. \end{aligned}$$

Again, if we multiply the expressions of t, t', t'', we shall get

$$\begin{aligned} tt't't'' &= (a-c)\,.\,(a^2-c^2)+(b-d)\,.\,(b^2-d^2) \\ &\quad -(a+c)\,(b-d)^2-(b+d)\,(a-c)^2; \end{aligned}$$

or,

$$\begin{aligned} tt't'' &= a^3+b^3+c^3+d^3+2\Sigma\,.\,abc \\ &\quad -(a^2b+a^2c+a^2d+b^2a+b^2c+b^2d \\ &\quad +c^2a+c^2b+c^2d+d^2a+d^2b+d^2c); \end{aligned}$$

and finally, by means of the formulæ in Sect. 9,

$$\begin{aligned} tt't'' &= (a+b+c+d)^3+8\Sigma\,.\,abc \\ &\quad -4(a+b+c+d)\times\Sigma\,.\,ab. \end{aligned}$$

If now we substitute the values computed by the preceding formulæ in the cubic equation

$$\begin{aligned} 0 = u^3 &- (t^2+t'^2+t''^2)u^2 \\ &+ (t^2t'^2+t^2t''^2+t'^2t''^2)u \\ &- t^2t'^2t''^2, \end{aligned}$$

we shall obtain the values of t^2, t'^2, t''^2, and consequently of t, t', t'', by solving that equation; and when t, t', t'', are known, we have

$$\begin{aligned} a+b+c+d &= a+b+c+d, \\ t &= a+b\varrho+c\varrho^2+d\varrho^3, \\ t' &= a+d\varrho+b\varrho^2+c\varrho^3, \\ t'' &= a+c\varrho+d\varrho^2+b\varrho^3; \end{aligned}$$

wherefore, because $0=1+\varrho+\varrho^2+\varrho^3$, we get

$$a=\frac{1}{4}\left\{a+b+c+d+t+t'+t''\right\},$$

$$b=\frac{1}{4}\left\{a+b+c+d+t\varrho^3+t'\varrho^2+t''\varrho\right\},$$

$$c=\frac{1}{4}\left\{a+b+c+d+t\varrho^2+t'\varrho+t''\varrho^3\right\},$$

$$d=\frac{1}{4}\left\{a+b+c+d+t\varrho+t'\varrho^3+t''\varrho^2\right\}.$$

And finally, by making $\varrho=-1$,

$$a=\frac{1}{4}\left\{a+b+c+d+t+t'+t''\right\},$$

$$b=\frac{1}{4}\left\{a+b+c+d-t+t'-t''\right\},$$

$$c=\frac{1}{4}\left\{a+b+c+d+t-t'-t''\right\},$$

$$d=\frac{1}{4}\left\{a+b+c+d-t-t'+t''\right\}.$$

In applying these formulæ, it is necessary to observe, that as the quantities t, t', t'', are found by extracting the square root, they may each have either the sign plus or the sign minus prefixed. But all ambiguity from this cause will be taken away, if it be observed that the expressions of a, b, c, d, will always give the same results, provided the signs of t, t', t'', be so determined as to satisfy the equation,

$$\begin{aligned} tt't'' &= (a+b+c+d)^3+8\Sigma\,.\,abc \\ &\quad -4(a+b+c+d)\times\Sigma\,.\,ab. \end{aligned}$$

For, if we suppose that the signs of t, t', t'', are so determined as to satisfy the equation mentioned, they cannot be varied so as still to satisfy the same equation, unless two of them be changed together; for, if one sign only be changed, or if all the three be changed together, the product $tt't''$ will have an opposite sign to what it had before, and the equation will no longer be satisfied. But the expressions of a, b, c, d, give the same set of values when the signs of any two of the letters t, t', t'', are changed together; so that, in order to have the true values of the quantities sought, no other rule for the signs of t, t', t'', is necessary than that they must be such as to satisfy the equations alluded to.

To apply the preceding investigation, we may take the equation

$$x^4+px^2+qx+r=0,$$

which wants the second term. Then,

$$\begin{aligned} o &= a+b+c+d, \\ p &= \Sigma\cdot ab, \\ -q &= \Sigma\,.\,abc, \\ r &= abcd: \end{aligned}$$

hence

$$\begin{aligned} t^2+t'^2+t''^2 &= -8p, \\ t^2t'^2+t^2t''^2+t'^2t''^2 &= 16p^2-64r, \\ tt't'' &= 8q: \end{aligned}$$

and t^2, t'^2, t''^2, are the roots of the cubic equation

$$u^3+8pu^2+16(p^2-4r)u-64q^2=0.$$

Having solved this equation, and found the values of t, t', t'', the signs of these quantities must next be determined so as to satisfy the equation,

$$tt't''=-8q;$$

and then we have these formulæ for computing the roots of the proposed equation, viz.

$$a=\frac{t+t'+t''}{4},$$

$$b=\frac{-t+t'-t''}{4},$$

$$c=\frac{t-t'-t''}{4},$$

$$d=\frac{-t-t'+t''}{4}.$$

These formulæ coincide with the method of solving biquadratic equations first proposed by Euler in his Algebra. But, in order to take away the ambiguity arising from the double sign of the square root, that celebrated mathematician uses two sets of expressions for the roots of the equation, viz.

$$\begin{aligned} a &= \frac{t+t'+t''}{4}, & a &= \frac{-t-t'-t''}{4}, \\ b &= \frac{-t+t'-t''}{4}, & b &= \frac{t-t'+t''}{4}, \\ c &= \frac{t-t'-t''}{4}, & c &= \frac{-t+t'+t''}{4}, \\ d &= \frac{-t-t'+t''}{4}, & d &= \frac{t+t'-t''}{4}, \end{aligned}$$

of which one set is the same with the formulæ given above, and the other is obtained by changing t, t', t'', into $-t$, $-t'$, $-t''$; the first set being directed to be used when $-8q$ is positive, and the other set when the same quantity is negative. This procedure is not so simple as that we have followed, which requires only one set of formulæ. It has even been the occasion of leading into error, in as much as it makes the signs of t, t', t'', depend entirely upon the sign of the given quantity $-8q$; whereas it is indispensable that, regard being had to the nature of the quantities t, t', t'', their signs shall be determined so as to satisfy the equation $tt't''=-8q$. This inadvertence of Euler has escaped the observation of most of the authors who have treated of biquadratic equations, and was first noticed by M. Bret, in the second volume of the *Correspondance sur l'Ecole Polytechnique.*

It may not be improper to notice briefly some of the other rules for biquadratic equations. These are chiefly two; the method of Descartes, which resolves the given equation into two quadratic factors; and the oldest method of all, invented by Louis Ferrari, a pupil of Cardan, which proceeds by transforming the given equation, so as to make it equal to the difference of two complete squares, and then extracting the square roots. However different from one another these two methods may at first seem, they are at bottom the same; and they are so far connected with that already investigated, that all the three lead to the same cubic equation.

Suppose that a, b, c, d, are the roots of the biquadratic equation

$$x^4-Ax^3+Bx^2-Cx+D=0;$$

then $x^2-(a+b)\,x+ab=0$, and $x^2-(c+d)\,x+cd=0$, are two quadratic factors, the product of which is equal to the given equation. Now,

$$A=a+b+c+d,$$
$$t=a+b-c-d;$$

wherefore, if we put $ab=p+y$, $cd=p-y$, the two factors will become

$$x^2-\frac{1}{2}(A+t)\,x+p+y=0,$$

$$x^2-\frac{1}{2}(A-t)\,x+p-y=0:$$

and if we multiply them, and equate the co-efficients of the product to the co-efficients of the given equation, we shall get

$$2p+\frac{1}{4}A^2-\frac{1}{4}t^2=B,$$
$$Ap+ty=C,$$
$$p^2-y^2=D.$$

And it is to be observed that, on account of the first two of these equations, p and y are both real quantities when t is a real quantity; so that, provided a real value of t can be found, the given equation is always resolved, by this method, into two quadratic factors free from imaginary expressions.

Now, by combining the equations just found, we shall get

$$\begin{aligned}0=t^6&-(3A^2-8B)\cdot t^4\\&+(3A^4-16A^2B+16B^2+16AC-64D)\cdot t^2\\&-(A^3-4AB+8C)^2,\end{aligned}$$

$$p=\frac{1}{2}B-\frac{1}{8}A^2+\frac{1}{8}t^2$$

$$y=\sqrt{\left(\frac{1}{2}B-\frac{1}{8}A^2+\frac{1}{8}t^2\right)^2-D}.$$

The first of these equations is a cubic, of which the root is t^2; and it is precisely the same with the cubic of the former method. As the last term of this equation is essentially positive, it follows that there is always one positive value of t^2, and one real value of t; wherefore, in consequence of what has been proved, the values of p and y, derived from the positive value of t^2, are in every case real quantities, which is no doubt an advantage in the practical application of the method.

If we wish to follow the process of Louis Ferrari, we may assume p, t, y, so as to render the expression

$$\left(x^2-\frac{1}{2}Ax+p\right)^2-\left(\frac{1}{2}tx+y\right)^2=0$$

identical with the given equation; and as this expression is no more than the product of the two quadratic factors of the last method, the quantities to be determined will be found by the formulæ already given.

Equations of the fifth degree.

The theory of permutations, which is successful in solving cubic and biquadratic equations, applies likewise to those of the fifth and higher orders. But, to use the words of Lagrange, "Passé le quatrième degré, la méthode, quoiqu' applicable en général, ne conduit plus qu'à des equations resolvantes de degres superieurs à celui de la proposée." Thus, in the case of equations of the fifth degree, the theory leads to a biquadratic equation, of which the co-efficients are to be found by resolving an equation of the sixth order.

There is, however, no doubt that the doctrine of permutations contains the principles from which we are to expect the resolution of equations of the higher orders, if the problem be possible. It may be alleged, with great probability, that the theory succeeds in the less complicated cases, because when the number of the roots is small, their permutations are soon exhausted, and we speedily arrive at those combinations of them which remain invariable, whatever be the order of the quantities combined. But when the number of the roots is greater than four, their permutations are very numerous, and at the same time the functions produced by combining them are very complicated; on which accounts it is difficult to conduct the investigation so as to arrive at a satisfactory conclusion, either accomplishing the intended purpose, or proving that the undertaking is impossible.

In the twelfth volume of the *Italian Society*, and in a work published at Modena in 1813, M. Paolo Ruffini has proved that no function of five letters can exist that is susceptible of only three or four different values when the letters are interchanged among one another in all possible ways. M. Cauchy, in the sixteenth volume of the *Journal de l'Ecole Polytechnique*, has demonstrated that a function of n letters, unless it have no more than two different values, cannot have a number of different values less than the prime number next below n. On these grounds it has been inferred that the resolution of equations of the fifth degree is in reality an impossible problem. (Lacroix, *Compt. des Elem. d'Algebre*, p. 61.) And if it be admitted that, in the process of resolution, no equations can occur except such as have symmetrical functions of the five letters for their co-efficients, the inference founded on the labours of the eminent mathematicians we have mentioned would be indisputable. But it is not impossible that the resolution of equations of a high order must be effected by gradually depressing an equation at first of great dimensions; and in this procedure we may arrive at equations, the co-efficients of which, although functions of the roots of the proposed equation, are not symmetrical functions, but partial expressions, susceptible of several values, according as the order of the letters that denote the roots is made to vary. On this supposition, the resolution of equations above the fourth order, by means of equations inferior in degree, would not be inconsistent with what has been proved.

Some particular classes of equations.

17. A method for solving equations of one order may be generalized so as to extend to a certain class in all orders. Thus De Moivre has found a species of equations

of every degree that have their roots similar to those of cubics, and which are solved by the formula

$$x = (q + \sqrt{q^2 - p^n})^{\frac{1}{n}} + (q - \sqrt{q^2 - p^n})^{\frac{1}{n}},$$

differing in no respect from the expression for resolving cubics, except that n is written in place of 3.

An equation may be depressed to a lower order when it is known that the roots have a given relation to one another. An instance of this has already occurred in the case of equal roots; for, the equal roots having been first found, the equation can be lowered by division. Reciprocal equations furnish another example of depression to a lower order, on account of a relation subsisting among the roots. A reciprocal equation is one of even dimensions, such that half the roots are respectively the reciprocals of the other half, in which case no alteration is produced in the equation when $\frac{1}{x}$ is substituted for x. In equations of this kind, the same co-efficients occur in the same order, and with the same signs, reckoning from either end; a description that likewise applies to some equations of odd dimensions, which, however, do not constitute a new class, being merely reciprocal equations, as defined above, multiplied by the factor $x + 1$. A reciprocal equation may always be depressed to half the dimensions, by transforming it so that the new unknown quantity shall be equal to $x + \frac{1}{x}$. It is sufficient to have mentioned these cases, which are fully treated of in all the elementary books.

Equations with only two terms, as $x^p - 1 = 0$, are the most extensive class that have been resolved by a general method. The successful application of analysis to this class of equations is extremely interesting, both in itself, and likewise because it is connected with the division of the circle into equal parts, and has occasioned the discovery of some curious and unexpected results respecting that problem. For these reasons, it appears proper to lay before our readers a short view of this branch of the doctrine of algebraic equations.

We have already shown, that, admitting the theory of angular sections, every equation with only two terms, as $x^p - 1 = 0$, may be completely resolved into its binomial and trinomial factors; and hence all its roots, possible and impossible, may be computed by means of the trigonometrical tables in common use. If we put $\varphi = \frac{360^\circ}{p}$, and denote by k any number less than $\frac{1}{2}p$, we have found that the equation $x^p - 1 = 0$ is divisible by the quadratic factor $x^2 - 2x, \cos. \varphi + 1$, and, consequently, that it has the two impossible roots,

$$x = \cos. k\varphi + \sin. k\varphi . \sqrt{-1},$$
$$x = \cos. k\varphi - \sin. k\varphi . \sqrt{-1}:$$

and, because $\cos. k\varphi = \cos. (p - k)\varphi$, and $-\sin. k\varphi = \sin. (p - k)\varphi$, the same two roots may be otherwise more symmetrically represented thus,

$$x = \cos. k\varphi + \sin. k\varphi . \sqrt{-1},$$
$$x = \cos. (p-k)\varphi + \sin. (p-k)\varphi . \sqrt{-1}.$$

Therefore, when p is odd, the equation $x^p - 1 = 0$ has one real root equal to 1; and when p is even, it has two real roots equal to ± 1; and in both cases the remaining roots are all impossible, and are found from the formula

$$x = \cos. k\varphi + \sin. k\varphi . \sqrt{-1},$$

by making k equal to all the integral numbers less than p in the one case, and less than $p - 1$ in the other. Nothing, therefore, can be more simple than the computation of the roots of such equations by means of the trigonometrical tables. But in seeking a general solution, it is required to investigate the roots without resorting to the properties of the circle, unless in so far as this may be necessary for solving similar equations inferior in degree to the one proposed. In this view the resolution of the equation $x^p - 1 = 0$, is equivalent to the division of the circle into p equal parts, granting the like division for all numbers less than p. And in order to render the investigation of the problem as simple as possible, it may be further observed, that it will be sufficient to consider the case when the exponent is a prime number; because, from this case, the other, when it is a composite number, can be readily deduced.

It will be proper to premise here a property of the roots of equations with only two terms, to which we shall have occasion continually to refer. The property in question depends upon this theorem, namely, when k is any number not a multiple of the prime number p, the remainders of the terms of the series

$$1 \times k, 2 \times k, 3 \times k \ldots (p-1) \times k,$$

when each is divided by p, are all different from one another; and, consequently, without regard to the order, they will coincide with the numbers 1, 2, 3, &c. less than p. If, therefore, we take any one of the impossible roots of the equation x^{p-1}, viz.

$$r = \cos. k\varphi + \sin. k\varphi \sqrt{-1},$$

all its powers with indices less than p, viz.

$$r^2 = \cos. 2k\varphi + \sin. 2k\varphi . \sqrt{-1},$$
$$r^3 = \cos. 3k\varphi + \sin. 3k\varphi . \sqrt{-1},$$
&c.

will be different from one another; and likewise they will coincide, without regard to the order, with the like powers of any other impossible root of the same equation: because, whatever number k stands for, the arcs are all different from one another, and, neglecting whole circumferences, constitute the same series of terms, although in different orders. Wherefore, p being a prime number, if r be one of the impossible roots of the equation $x^p - 1 = 0$, all the roots will be represented by the terms of the geometrical progression

$$r^0, r^1, r^2, r^3, \ldots . r^{p-1};$$

for every one of these terms satisfies the given equation, and it has been shown that they are all different from one another.

When p is a composite number, the same property does not belong to all the roots of the equation $x^p - 1 = 0$, but only to some of them. It belongs generally to the root

$$r = \cos. k\varphi + \sin. k\varphi . \sqrt{-1},$$

when k is either equal to unit, or to any number that has no common divisor with p; in which cases all the powers of r are roots of the equation $x^p - 1 = 0$, and all different from one another, when the exponents are different and less than p.

If the equation $x^p - 1 = 0$ be divided by the binomial factor $x - 1$, we shall get

$$x^{p-1} + x^{p-2} + x^{p-3} \ldots + x + 1 = 0;$$

and this being a reciprocal equation, it can be farther depressed to half the dimensions. In this manner we obtain the solution of $x^7 - 1 = 0$, which is reduced to a cubic; but, by the same procedure, the equation next in order, viz. $x^{11} - 1 = 0$, can be lowered only to the fifth degree, for equations of which class there is no rule. Nevertheless this last equation has been solved by Vandermonde, to whom, and to Lagrange, we are mainly indebted for disengaging the resolution of equations from the complicated operations of algebra, and for substituting, in their place, reasonings founded on the doctrine of combinations. The author has not explained particularly the process by which his solution was obtained; he gives it as a result of his theory, which, although it fails in general for equations above the fourth degree, succeeds in this instance on account of particular relations between the roots. Similar relations subsist between the roots of any other binomial equation when the exponent is a prime number; and, in consequence, a like mode of investigation will apply, as indeed the author has expressly said. But this procedure would unavoidably be attended in every new instance with very long calculations; and it appears hardly possible to arrive in this way at any general method that would apply to all equations of the class in a regular manner, and without considerations drawn from each particular case.

M. Gauss, in a work entitled *Disquisitiones Arithmeticæ*, replete with original and important matter, applied a property of prime numbers to the solution of binomial equations, which removed every difficulty, and led to a theory that unites simplicity and generality. If we suppose that p is a prime number, and resolve $p - 1$ into its component factors, so that $p - 1 = a^{\lambda} . b^{\mu} . c^{\gamma}$. &c., a, b, c, &c. being prime numbers, M. Gauss has proved that the solution of the equation $x^p - 1 = 0$, or, which is the same thing, the division of the circle into p equal parts, can be effected by solving successively λ equations of a dimensions, μ equations of b dimensions, γ equations of c dimensions, &c. Thus, if $p = 13$, then, because $13 - 1 = 3 \times 2^2$, the roots of $x^{13} - 1 = 0$ can be found, or a polygon of 13 sides can be inscribed in a circle, by solving a cubic and two quadratic equations in succession. In certain cases, when a prime number comes under the form $2^n + 1$, as 17, 257, &c. the division of the circle will require the solution of equations no higher than the second order; whence this unexpected consequence has resulted from the theory of M. Gauss, that the inscription of a polygon of 17, or 257 sides in a circle, which are problems that have always been understood to transcend the limits of the elementary geometry, can, nevertheless, be constructed by the operations admitted in that science.

A work replete with so many interesting discoveries as the *Disquisitiones Arithmeticæ* could not fail to excite the attention of mathematicians. Legendre, in republishing his *Essay on the Theory of Numbers*, has added to it an exposition of M. Gauss's theory of binomial equations; and the same theory is the subject of the 14th note in the second edition of Lagrange's *Treatise on Numerical Equations.* No part of the mathematics could pass through the hands of men of so much ability without receiving great improvement. Lagrange has shown that it is not necessary to go through the several intermediate equations that make so essential a part in the investigation of M. Gauss; and, by this means, he has reduced the solution of equations with two terms to the utmost simplicity of which it is capable. But, in one respect, it must be admitted that the procedure of the illustrious geometer is imperfect. Although it arrives, by a short investigation, at the partial quantities that by their additions form the expressions of the roots sought, it leaves indeterminate the order in which they are to be combined. M. Gauss has avoided ambiguity in this respect by deducing from one of the quantities all the other parts of the same expression; but, amidst a multiplicity of different systems of values that may be deduced from the partial quantities, Lagrange has given no clue to guide to the true one.

In laying before our reader some account of this interesting branch of the theory of algebraic equations, we shall view the subject in a light somewhat different from that in which it has hitherto been placed. Instead of seeking directly the roots of binomial equations, we shall apply the principles of M. Gauss's theory immediately to the division of the circle into equal parts, by taking the arcs of the circumference in that order to which the method owes all its success. This procedure is attended with some advantages. In the first place, the algebraic expressions of the quantities sought, represented by $\cos. \frac{k \times 360°}{p}$, are more simple than those of the imaginary roots of the corresponding binomial equation; and, in the second place, the same expressions, having always real values, are better fitted for application than the roots of binomial equations, which require to be further reduced to prepare them for calculation.

Before entering on the principal problem, it is necessary to say something of that property of numbers on which the whole theory depends. Supposing p to be any prime number, Euler has distinguished by the name of a *Primitive Root* any number less than $p - 1$, such that, if we take the series of all its powers with indices less than p, and in each power reject the multiples of p it contains, the several remainders are all different from one another, and, consequently, paying no regard to the order, they will coincide with the numbers 1, 2, 3, &c. less than p. It has been proved that, for every prime number, there are as many primitive roots as there are numbers less than $p - 1$, which have no common divisor with it. The existence of such numbers in every case is therefore demonstrated; but no direct method of finding them has yet been published with which we are acquainted.

We gladly seize the present occasion of laying down a rule for finding the primitive roots of a prime number. But first we must premise, that when any proposed number is said to satisfy the equation $x^m + 1 = 0$, it is always understood that the multiples of the prime number p are rejected; and the meaning is, that, when the given number is substituted for x, the whole result is divisible by p without any remainder.

Now, let p be a prime number, and 2, a, b, c, &c. the prime divisors of $p - 1$, so that $p - 1 = 2^{\pi} . a^{\lambda} . b^{\mu} . c^{\gamma}$. &c.: then every primitive root will satisfy the first of the following equations without satisfying any of the rest, viz.

$$x^{\frac{p-1}{2}} + 1 = 0,$$

$$x^{\frac{p-1}{2a}} + 1 = 0,$$

$$x^{\frac{p-1}{2b}} + 1 = 0,$$

$$x^{\frac{p-1}{2c}} + 1 = 0,$$

&c.

And, on the other hand, every number not a primitive root, which satisfies the first equation, will at the same time satisfy one, or more, or all, of the other equations.

But the numbers which satisfy the first equation are exclusively those which are not found among the remainders of the series of square numbers divided by p.

Wherefore, setting aside the first equation, if we seek among the non-residual numbers for such as satisfy none of the remaining equations, the numbers so found will be the primitive roots sought.

When one primitive root is found by this method, all the rest may be directly obtained from it. For, if 1, w, w', w'', &c. . . . $n^{(n)}$, represent all the numbers less than $p - 1$ and prime to it; then a being one of the primitive roots, all the roots will be equal to the series of powers,

$$a, a^w, a^{w'}, a^{w''}, \ldots\ldots a^{w^{(n)}},$$

rejecting always the multiples of p.

The demonstration of these properties would lead us aside from our present purpose; and we shall be content with adding some examples for the sake of illustration.

Let $p = 11$: then $\frac{p - 1}{2} = 5$, and $\frac{p - 1}{2 . 5} = 1$; so that in this case, the only equation of exclusion is $x + 1 = 0$, which admits only one solution, viz. $x = p - 1 = 10$. Therefore all the non-residual numbers except 10 are the primitive roots; namely, 2, 6, 7, 8. We may extend this conclusion to every case when $\frac{p - 1}{2}$ is a prime number, as 7, 23, 47, &c.; in all which instances all the non-residuals, except $p - 1$, are the primitive roots.

Next, let $p = 17$; then $\frac{p - 1}{2} = 8 = 2^3$; and there are no equations of exclusion. In this case, therefore, all the non-residuals, without exception, are primitive roots; and the same thing is true of every prime number of the form $2^n + 1$, such as 5, 257, &c.

Let $p = 13$; then $\frac{p - 1}{2} = 2 \times 3$; and the only equation of exclusion is

$$x^2 + 1 = 0,$$

which admits only two solutions, viz. $x = 5$ and $x = 8$. In this instance, therefore, all the non-residual numbers, except 5 and 8, are the primitive roots.

Let $p = 31$; then $\frac{p - 1}{2} = 3 \times 5$; and we have two equations of exclusion, viz.

$$x^3 + 1 = 0,$$
$$x^5 + 1 = 0.$$

The non-residual numbers are

3, 6, 11, 12, 13, 15, 17, 21, 22, 23, 24, 26, 27, 29, 30.

Of these numbers the first, viz. 3, is a primitive root, since it satisfies neither of the two equations; and as the numbers less than 30, and prime to it, are 1, 7, 11, 13, 17, 19, 23, 29; all the primitive roots of 31 are as follows: viz. $3^1 = 3$, $3^7 = 17$, $3^{11} = 13$, $3^{13} = 24$, $3^{17} = 22$, $3^{19} = 12$, $3^{23} = 11$, $3^{29} = 21$. With respect to the other non-residual numbers, it will be found on trial that the first equation is satisfied by 6 and 26; the second by 15, 23, 27, 29; and both equations by 30.

We are now prepared to enter upon the solution of the problem for dividing the circle into as many equal parts as there are units in the prime number $p = 2n + 1$. If we conceive a polygon of p sides, to be inscribed in a circle, it will be admitted that the centre of gravity of the polygon coincides with the centre of the circle. Wherefore, if perpendiculars be drawn to any diameter of the circle from all the angles of the polygon, it follows, from the nature of the centre of gravity, that the sum of the cosines lying on one side of the centre of the circle will be equal to the sum of the cosines lying on the other side. Let $\varphi = \frac{360°}{p}$; and put u for the arc intercepted between the diameter and any angle of the polygon, then we shall have this equation, viz.

$$0 = \cos.u + \cos.(\varphi + u) + \cos.(2\varphi + u) \ldots . + \cos.(2n\varphi + u),$$

which is no more than the analytical expression of the geometrical property just mentioned. Now, suppose that the diameter passes through one of the angles of the polygon; then $u = 0$, and the equation becomes

$$0 = 1 + \cos.\varphi + \cos.2\varphi + \cos.3\varphi \ldots . + \cos.2n\varphi.$$

Let a be one of the primitive roots of the prime number p; then rejecting multiples of p, and paying no regard to the order, the terms of the geometrical progression,

$$a, a^2, a^3, a^4 \ldots\ldots a^{2n},$$

will be equal to the several numbers less than p. Wherefore, in the two series of arcs,

$$a\varphi, a^2\varphi, a^3\varphi, a^4\varphi \ldots\ldots a^{2n}\varphi,$$
$$\varphi, 2\varphi, 3\varphi, 4\varphi \ldots\ldots 2n\varphi,$$

every arc in the geometrical progression will either be equal to some one in the arithmetical progression, or will differ from it by a whole circumference, or circumferences. Hence the cosines of the first series of arcs may be substituted in the last equation for the cosines of the other series; and thus we have

$$-1 = \cos.a\varphi + \cos.a^2\varphi + \cos.a^3\varphi \ldots + \cos.a^{2n}\varphi.$$

Again, by Fermat's theorem, $a^{2n} - 1 = (a^n + 1)(a^n - 1)$ = a multiple of p; and because no primitive root of a prime number is the remainder of a square divided by that number, we have $a^n + 1$ = a multiple of p; and consequently $a^{n+\lambda} + a^\lambda$ = a multiple of p. It follows, therefore, that $a^{n+\lambda}\varphi + a^\lambda\varphi$ is equal to a multiple of the circumference of the circle; and hence,

$$\cos.a^{n+\lambda}\varphi = \cos.a^\lambda\varphi \qquad (A)$$

From this it appears that the cosines in the last equation may be distributed into two equal sums; one containing the cosines of all arcs from $a\varphi$ to $a^n\varphi$ inclusively, and the other the remaining cosines; consequently

$$-\frac{1}{2} = \cos.a\varphi + \cos.a^2\varphi + \cos.a^3\varphi \ldots \cos.a^n\varphi;$$

and because $\cos.a^n\varphi = \cos.\varphi$,

$$-\frac{1}{2} = \cos.\varphi + \cos.a\varphi + \cos.a^2\varphi \ldots\ldots + \cos.a^{n-1}\varphi. \quad (1)$$

Let $r = \frac{360°}{n}$; and put

$$e = \cos.r + \sin.r\sqrt{-1};$$

then all the powers of e with indices less than n will be different from one another, and all of them roots of the equation $e^n - 1 = 0$, the solution of which requires the division of the circle into only n, or $\frac{p - 1}{2}$, equal parts.

In what follows, we shall have continual occasion to consider the expression

$$\cos.a^\lambda\varphi + e^m\cos.a^{\lambda+1}\varphi + e^{2m}\cos.a^{\lambda+2}\varphi \ldots + e^{(n-1)m}\cos.a^{\lambda+n-1}\varphi;$$

and it will therefore be convenient to adopt an abridged mode of writing it. Now, the expression will be wholly known, and can be constructed when the two indices λ and m are given; and we may therefore denote it by the symbol $f(\lambda, m)$, placing always the index of a before the other. We shall invariably make the index of a positive, and suppose it reduced below n by means of the formula (A). In like manner we shall suppose that the index of e is always reduced below n by suppressing the multiples of n; and we shall write it sometimes positive and sometimes negative, observing that the negative indices may be always rendered positive by supplying the proper multiples of n; thus,

$$e^{-im} = e^{n-im} = e^{2n-im} = e^{3n-im}, \text{ \&c.}$$

According to the notation just explained, we have

$$f(o,m) = \cos.\varphi + e^{m} \cos. a\varphi + e^{2m} \cos. a^2\varphi .. + e^{(n-1)m} \cos. a^{n-1}\varphi,$$

$$f(o,-m) = \cos.\varphi + e^{-m} \cos. a\varphi + e^{-2m} \cos. a^2\varphi \ldots + e^{-(n-1)m} \cos. a^{n-1}\varphi.$$

And because $e^{\circ} = e^{n} = e^{-n} = 1$, the symbols $f(o, o)$, $f(o, n)$, $f(o, -n)$, will represent the series of cosines in the equation (1); so that we have

$$-\frac{1}{2} = f(o, o) = f(o, n) = f(o, -n).$$

The following formula is no more than a corollary from the preceding notation, viz.

$$e^{-\lambda m} \times f(o, m) = f(\lambda, m). \quad \text{(B)}$$

By means of the trigonometrical formula in common use, any powers and products of the cosines of the arc φ and its multiples may be reduced to a series of terms, containing the like cosines multiplied by given co-efficients. Wherefore, because $\cos. p\varphi = 1$, and likewise because the cosines of all arcs greater than $p\varphi$, $2p\varphi$, $3p\varphi$, &c. may be reduced to the cosines of arcs less than $p\varphi$, it follows that every rational and integral function of $\cos. \varphi$, $\cos. 2\varphi$, $\cos. 3\varphi$, &c. may be brought under this form of expression, viz.

$$\text{A} + \text{B} \cos.\varphi + \text{C} \cos. 2\varphi + \text{D} \cos. 3\varphi \ldots + \text{N} \cos. 2n\varphi.$$

Now, if we suppose the function we are considering to be such, that it retains the same value when any of the multiple arcs 2φ, 3φ, &c. is substituted for φ, the transformed expression will be possessed of the same property. But if we actually substitute the arcs 2φ, 3φ, &c. for φ in the foregoing expression, it will become successively

$$\text{A} + \text{B} \cos. 2\varphi + \text{C} \cos. 4\varphi + \text{D} \cos. 6\varphi +, \text{\&c.}$$
$$\text{A} + \text{B} \cos. 3\varphi + \text{C} \cos. 6\varphi + \text{D} \cos. 9\varphi +, \text{\&c.}$$
$$\text{\&c.}$$

each line containing the same cosines, although in a different order, because the series of arcs is the same when whole circumferences, or the multiples of $p\varphi$, are rejected; and all these expressions cannot have the same value unless $\text{B} = \text{C} = \text{D} = \text{\&c.}$; that is, unless the expression be of this form, viz.

$$\text{A} + \text{B} (\cos.\varphi + \cos. 2\varphi + \cos. 3\varphi \ldots + \cos. 2n\varphi),$$

which, in consequence of what was before proved, is equal to $\text{A} - \text{B}$. It is therefore demonstrated that every rational and integral function of $\cos. \varphi$, $\cos. 2\varphi$, $\cos. 3\varphi$, &c., which remains unchanged when any of the multiple arcs 2φ, 3φ, &c. is substituted for φ, has for its value an expression without cosines, and depending only upon the nature of the function.

If we introduce the arcs in geometrical instead of those n arithmetical progression, it is obvious that the substiution of the multiple arcs 2φ, 3φ, &c., for φ, is equivalent o the changing of φ into $a\varphi$, $a^2\varphi$, $a^3\varphi$, &c.; and hence any ational and integral function of the cosines of φ and its multiples, which remains invariable when φ is changed nto $a\varphi$, $a^2\varphi$, $a^3\varphi$, &c. is a quantity independent of the coines, or has its value expressed by a function from which he cosines are eliminated.

What has now been proved will enable us to appreciate he advantage arising from the introduction of the arcs in eometrical in place of those in arithmetical progression, in which principally consists the improvement that this theory owes to M. Gauss. The solution of the problem turns upon finding those functions of $\cos. \varphi$, $\cos. 2\varphi$, $\cos. 3\varphi$, &c. which have determinate values independent of the cosines; which functions, it has been proved, remain invariable when any of the multiple arcs 2φ, 3φ, &c. is substituted for φ. Now, although the substitution of any multiple arc, in place of the arc itself, always reproduces the same series of cosines, yet the order is irregular, and varies with every different multiple arc; and this circumstance makes it difficult to investigate what change the substitution will effect in a given function. On the other hand, by introducing the arcs in geometrical progression, the same order is still preserved, whatever substitution be made; and by this means every facility possible is obtained for investigating the functions sought.

The following properties are deducible from what has been proved. First, if m, m', m'', &c. be any numbers, none of which is equal to zero, or a multiple of n, and such that their sum is equal to n, or to a multiple of n, the product

$$f(o,m) \times f(o, m') \times f(o, m''), \text{ \&c.}$$

will be independent of the cosines of φ and its multiples, or will be an expression containing only the powers of e multiplied by numeral co-efficients.

For by the formula (B) we have

$$e^{-\lambda m} \times f(o, m) = f(\lambda, m)$$
$$e^{-\lambda m'} \times f(o, m') = f(\lambda, m')$$
$$e^{-\lambda m''} \times f(o, m'') = f(\lambda, m'')$$
$$\text{\&c.} \qquad \text{\&c.}$$

Therefore, by multiplying and observing that $e^{-\lambda m} \times e^{-\lambda m'} \times e^{-\lambda m''} \times, \text{\&c.} = 1$, because $\lambda \times (m + m' + m'' +, \text{\&c.})$ is a multiple of n, we get

$$f(o, m) \times f(o, m') \times f(o, m''), \text{\&c.} = f(\lambda, m) \times f(\lambda, m') \times f(\lambda, m''), \text{\&c.}$$

which shows that the product in question is not altered when φ is changed into $a^{\lambda}\varphi$. Consequently, according to what was before proved, the product is independent of the cosines.

It follows, as a corollary, that the product

$$f(o, m) \times f(o, -m)$$

is independent of the cosines.

Next, if m, m', m'', &c. be any numbers, and $s = m + m' + m''$, &c.; and if neither s nor any of the numbers m, m', m'', &c. be a multiple of n, we shall have

$$f(o, m) \times f(o, m') \times f(o, m''), \text{\&c.} = \text{M} \times f(o, s),$$

the quantity M being independent of the cosines, and containing only the powers of e multiplied by numeral co-efficients.

For, by the property already demonstrated, and its corollary, we have

$$f(o, m) \times f(o, m') \times f(o, m'') \times f(o, -s) = \text{A}$$
$$f(o, s) \times f(o, -s) = \text{A}';$$

A and A′ being quantities independent of the cosines. Therefore, by exterminating $f(o, -s)$, we get

$$f(o, m) \times f(o, m') \times f(o, m'') \times, \text{\&c.} = \frac{\text{A}}{\text{A}'} . f(o, s).$$

The foregoing properties are the foundations of the theory. But it is not enough to establish the principles by a general demonstration; it is also necessary to be able to compute the numerical values that occur in the application to particular problems. Therefore, supposing that m and m' are two numbers, and $s = m + m'$, none of the three numbers s, m, m', being a multiple of n, it is proposed to find the value of A in the equation

$$f(o, m) \times f(o, m') = \mathrm{A} \times f(o, s).$$

For this purpose, set down the several terms of $f(o, m')$ in their order; and below them write the terms of $f(o, m)$, placing first any term, as $e^{\lambda m} \cos.\, a^{\lambda}\varphi$, and the rest in their order, in this manner:

$$\cos.\,\varphi + e^{m'} \cos.\, a\,\varphi + e^{2m'} \cos.\, a^2\,\varphi \ldots\ldots + e^{(n-1)m'} \cos.\, a^{n-1}\,\varphi,$$

$$e^{\lambda m} \cos.\, a^{\lambda\varphi} + e^{(\lambda+1)m} \cos.\, a^{\lambda+1}\varphi + e^{(\lambda+2)m} \cos.\, a^{\lambda+2}\varphi \ldots + e^{(\lambda+n-1)m} \cos.\, a^{\lambda+n-1}\varphi.$$

Now, let every term in the lower line be multiplied into that which stands above it; and, separating the factor $e^{\lambda m}$, which is common to each product, let the symbol $e^{\lambda m} \times \Psi(\lambda)$ represent the sum of all the products; then

$$\Psi(\lambda) = \cos.\,\varphi \cos.\, a^{\lambda}\varphi + e^{s} \cos.\, a\,\varphi \cos.\, a^{\lambda+1}\varphi \ldots + e^{(n-1)s} \cos.\, a^{n-1}\varphi \cos.\, a^{\lambda+n-1}\varphi.$$

If we repeat this operation, so as to make every term of the lower line stand first in succession, it is evident that, by this means, every term of $f(o, m')$ will be multiplied by all the terms of $f(o, m)$; so that the sum of all the results will be the product sought. We therefore obtain

$$f(o, m) \times f(o, m') = \Psi(o) + e^{m}\Psi(1) + e^{2m}\Psi(2) \ldots + e^{(n-1)m}\Psi(n-1).$$

Let $a^{\lambda} + 1 = w$, and $a^{\lambda} - 1 = w'$; then, because the product of the cosines of the two arcs is equal to half the sum of the cosines of the sum and difference of the two arcs, we shall have

$$\Psi(\lambda) = \frac{1}{2}\left\{\cos.\, w\varphi + e^{s} \cos.\, a \,.\, w\varphi + e^{2s} \cos.\, a^2 \,.\, w\varphi +, \&c.\right\} + \frac{1}{2}\left\{\cos.\, w'\varphi + e^{s} \cos.\, a \,.\, w'\varphi + e^{2s} \cos.\, a^2 . w'\varphi +, \&c.\right\}.$$

In the first place, when $\lambda = 0$, $w = 2$, $w' = 0$; therefore

$$\Psi(o) = \frac{1}{2}\left\{\cos.\, 2\varphi + e^{s} \cos.\, a \,.\, 2\varphi + e^{2s} \cos.\, a^2 \,.\, 2\varphi \ldots e^{(n-1)s} \cos.\, a^{n-1} \,.\, 2\varphi\right\} + \frac{1}{2}\left\{1 + e^{s} + e^{2s} + e^{3s} \ldots + e^{(n-1)s}\right\}.$$

But $e^{n} - 1 = 0$; and hence $e^{ns} - 1 = 0$; or

$$0 = (1 - e^{s}) \,.\left\{1 + e^{s} + e^{2s} +, \&c. \ldots + e^{(n-1)s}\right\}:$$

and, according to the value assumed for e, the equation $1 - e^{s} = 0$ cannot take place when s is not a multiple of n; wherefore

$$0 = 1 + e^{s} + e^{2s} + e^{3s} \ldots + e^{(n-1)s}.$$

Now, if we put $a^{i} = 2$, we shall get

$$\Psi(o) = \frac{1}{2} f(i, s) = \frac{1}{2}\left\{\cos.\,.\, a^{i}\varphi + e^{s} \cos.\, a^{i+1}\varphi + e^{2s} \cos.\, a^{i+2}\varphi +, \&c.\right\}$$

Wherefore, on account of the formula (B), we finally get

$$\Psi(o) = \frac{1}{2} e^{-is} \times f(o, s).$$

Next, when λ is not equal to zero, let $h(\lambda)$ and $h'(\lambda)$ denote the numbers derived from λ by means of the equations

$$a^{\lambda} + 1 = a^{h(\lambda)},$$

$$a^{\lambda} - 1 = a^{h'(\lambda)};$$

then, by substituting $a^{h(\lambda)}$ and $a^{h'(\lambda)}$ for w and w', we shall get

$$\Psi(\lambda) = \frac{1}{2} f\Big(h(\lambda), s\Big) + \frac{1}{2} f\Big(h'(\lambda), s\Big):$$

and, on account of the formula (B),

$$\Psi(\lambda) = \left\{\frac{1}{2} e^{-(\lambda)s} + \frac{1}{2} e^{-h'(\lambda)s}\right\} . f(o, s).$$

Now, collecting all the parts in the expression of $f(o, m) \times f(o, m')$, we shall get these formulæ, viz.:

$$\left.\begin{aligned} f(o, m) \times f(o, m') &= \mathrm{A} \times f(o, s) \\ \mathrm{A} = \frac{1}{2} e^{-is} &+ \frac{1}{2} e^{m-h(1)s} + \frac{1}{2} e^{m-h'(1)s} \\ &+ \frac{1}{2} e^{2m-h(2)s} + \frac{1}{2} e^{2m-h'(2)s} \\ &+ \frac{1}{2} e^{3m-h(3)s} + \frac{1}{2} e^{3m-h'(3)s} \\ &\quad \&c. \qquad\qquad \&c \end{aligned}\right\} \quad (2)$$

As nothing changes in the expression of A except the indices m and s, it may be denoted by the abridged symbol (m, s), in which it is obvious that m' may be substituted for m; so that

$$\mathrm{A} = (m, s) = (m', s).$$

When s is equal to n, and $m' = n - m$, the product in question becomes $f(o, m) \times f(o, -m)$, which has been proved to be a quantity independent of the cosines. In this case, therefore, we shall have

$$f(o, m) \times f(o, -m) = \mathrm{B};$$

B being a quantity from which the cosines are eliminated, and which is now to be investigated.

If, in the foregoing case, we suppose $m' = n - m$ and $s = n$, we shall get

$$f(o, m) \times f(o, -m) = \Psi(o) + e^{m}\Psi(1) + e^{2m}\Psi(2) \ldots e^{(n-1)m}\Psi(n-1):$$

but here, because $e^{s} = e^{n} = 1$, e and its powers disappear from the expression of $\Psi(\mu)$, and we have

$$\Psi(\lambda) = \cos.\,\varphi \cos.\, a^{\lambda}\varphi + \cos.\, a\varphi \cos.\, a^{\lambda+1}\varphi + \cos.\, a^2\varphi \times \cos.\, a^{\lambda+2}\varphi +, \&c.;$$

and, by expanding the products of the cosines, as before,

$$\Psi(\lambda) = \frac{1}{2}\left\{\cos.\, w\varphi + \cos.\, a \,.\, w\varphi + \cos.\, a^2 w\varphi \ldots + \cos.\, a^{n-1} \,.\, w\varphi\right\} + \frac{1}{2}\left\{\cos.\, w'\varphi + \cos.\, a \,.\, w'\varphi + \cos.\, a^2 \,.\, w'\varphi \ldots + \cos.\, a^{n-1} \,.\, w'\varphi\right\}.$$

When $\lambda = 0$, $w = 2$, $w' = 0$; therefore

$$\Psi(o) = \frac{1}{2} . \left\{\cos.\, 2\varphi + \cos.\, a \,.\, 2\varphi + \cos.\, a^2 \,.\, 2\varphi \ldots + \cos.\, a^{n-1} \,.\, 2\varphi\right\}$$

$$+\frac{1}{2}\left\{1+1+1+1+1\,\ldots\ldots\ldots+1\right\}.$$

But no alteration is made in equation (1) when we substitute, instead of the arc φ, any one of its multiples, or, which is the same thing, change φ into $a\varphi$, $a^2\varphi$, &c.; because such substitution or change continually reproduces the same cosines. Thus it appears that the sum of the n cosines in $\Psi(o)$ is equal to $-\frac{1}{2}$; and we have

$$\Psi(o)=\frac{n}{2}-\frac{1}{4}.$$

For every other value of λ, w and w' are neither of them equal to zero, nor to a multiple of n; wherefore, according to what has just been said, the sum of the n cosines in each of the two parts of $\Psi(\lambda)$ is equal to $-\frac{1}{2}$; and thus, when λ is not equal to zero, we have

$$\Psi(\lambda)=\frac{1}{2}\times-\frac{1}{2}+\frac{1}{2}\times-\frac{1}{2}=-\frac{1}{2}.$$

By substituting the values of $\Psi(o)$ and $\Psi(\lambda)$, we get

$$f(o,m)\times f(o,-m)=$$
$$\frac{n}{2}-\frac{1}{4}-\frac{1}{2}\left(e^{m}+e^{2m}+e^{3m}\,\ldots+e^{(n-1)m}\right).$$

But, as was already proved,

$$-1=e^{m}+e^{2m}+e^{3m}\,\ldots.+e^{(n-1)m}:$$

wherefore

$$f(o,m)\times f(o,-m)=\frac{n}{2}-\frac{1}{4}+\frac{1}{2}=\frac{2n+1}{4}=\frac{1}{4}p.$$

Now, if we put $k^2=\frac{1}{4}p$, we have finally

$$f(o,m)\times f(o,-m)=k^2\,\ldots.(3).$$

When n is an even number, it is obvious that $f\left(o,\frac{n}{2}\right)=f\left(o,-\frac{n}{2}\right)$: therefore it follows as a corollary, that in this case

$$f\left(o,\frac{n}{2}\right)=f\left(o,-\frac{n}{2}\right)=\pm k=\pm\frac{1}{2}\sqrt{p}.$$

By applying the equation (2), first to the indices m and m', and then to the indices $n-m$ and $n-m'$, or to m and m' taken negatively, we deduce

$$f(o,m)\times f(o,m')=(m,s)\times f(o,s),$$
$$f(o,-m)\times f(o,-m')=(-m,-s)\times f(o,-s):$$

and by multiplying we shall get, on account of equation (3), this remarkable formula, viz.

$$(m,s)\times(-m,-s)=k^2\,\ldots(4).$$

By successive applications of the equation (2), we get

$$f(o,1)\times f(o,1)=(1,2)\times f(o,2),$$
$$f(o,1)\times f(o,2)=(1,3)\times f(o,3),$$
$$f(o,1)\times f(o,3)=(1,4)\times f(o,4),$$
&c.

By combining these equations, and writing P for f, $(o,1)$, we deduce

$$P^2=(1,2)\,.\,f(o,2),$$
$$P^3=(1,2)\,.\,(1,3)\,.\,f(o,3),$$
$$P^4=(1,2)\,.\,(1,3)\,.\,(1,4)\,.\,f(o,4),$$
&c.

Wherefore, when n is an even number,

$$P^{\frac{n}{2}}=(1,2).(1,3).(1,4)\,\ldots.\left(1,\frac{n}{2}\right).f\left(o,\frac{n}{2}\right);$$

and, by squaring and observing that, by equation (3), $\left\{f\left(o,\frac{n}{2}\right)\right\}^2=k^2$, we get

$$P^n=(1,2)^2.(1,3)^2.(1,4)^2\ldots\left(1,\frac{n}{2}\right)^2.k^2. \qquad (5).$$

When n is an odd number, we have, in like manner,

$$P^{\frac{n-1}{2}}=(1,2).(1,3).(1,4)\ldots\left(1,\frac{n-1}{2}\right)\times$$
$$f\left(o,\frac{n-1}{2}\right),$$
$$P^{\frac{n+1}{2}}=(1,2).(1,3).(1,4)\ldots\left(1,\frac{n+1}{2}\right)\times$$
$$f\left(o,\frac{n+1}{2}\right);$$

but, by equation (3), $f\left(o,\frac{n-1}{2}\right)\times f\left(o,\frac{n+1}{2}\right)=k^2$;

wherefore $P^n=(1,2)^2.(1,3)^2.(1,4)^2\ldots.\left(1,\frac{n-1}{2}\right)^2.$

$$\left(1,\frac{n+1}{2}\right).k^2\ldots(6).$$

Again, from the preceding expressions we get

$$f(o,2)=\frac{1}{(1,2)}.P^2;$$

and, by equation (4),

$$f(o,2)=\frac{(-1,-2)}{k^2}.P^2.$$

In like manner,

$$f(o,3)=\frac{(-1,-2)}{k^2}.\frac{(-1,-3)}{k^2}.P^3,$$
$$f(o,4)=\frac{(-1,-2)}{k^2}.\frac{(-1,-3)}{k^2}.\frac{(-1,-4)}{k^2}.P^4,$$
&c.

These formulæ need only be continued till we obtain the value of the function $f\left(o,\frac{n-2}{2}\right)$ when n is even, and of $f\left(o,\frac{n-1}{2}\right)$ when n is odd; the remaining functions $f(o,n-2)$, $f(o,n-3)$, &c. or, which is the same thing, $f(o,-2)$, $f(o-3)$, &c. being derived from the preceding values merely by changing the signs of the different indices of e. Thus, if we write P′ for $f(o,-1)$, we shall have

$$f(o,-2)=\frac{(1,2)}{k^2}.P'^2,$$
$$f(o,-3)=\frac{(1,2)}{k^2}.\frac{(1,3)}{k^2}.P'^3,$$
$$f(o,-4)=\frac{(1,2)}{k^2}.\frac{(1,3)}{k^2}.\frac{(1,4)}{k^2}.P'^4,$$
&c.

Now, ϱ being any number less than n, it has been shown that

$$o=1+e^{\varrho}+e^{2\varrho}+e^{3\varrho}\,\ldots.+e^{(n-1\varrho)}:$$

and hence if we attend to the nature of functions $f(o,o)$, $f(o,1)$, $f(o,2)$, &c. we shall readily get

$$\cos.\,a^{\varrho}\varphi=$$
$$\frac{f(o,o)}{n}+\frac{1}{n}.\left\{e^{-\varrho}.f(o,1)+e^{-2\varrho}f(o,2)+e^{-3\varrho}\right.$$
$$\left.f(o,3)+,\ \&c.\right\};$$

or, by arranging the terms differently, and because

$$f(o, o) = -\frac{1}{2},$$

$$\cos. a^{\varrho}\varphi = -\frac{1}{2n} + \frac{1}{n}.\left\{e^{-\varrho} f(o, 1) + e^{\varrho}.f(o, -1)\right\}$$
$$+\frac{1}{n}.\left\{e^{-2\varrho}.f(o, 2) + e^{2\varrho}.f(o, -2)\right\}$$
$$+\frac{1}{n}.\left\{e^{-3\varrho}.f(o, 3) + e^{3\varrho}.f(o, -3)\right\}$$
&c.

and it is to be observed that, when n is even, the last term is the single quantity $\frac{1}{n} \times e^{-\frac{n}{2}\varrho} \times f\left(o, \frac{n}{2}\right)$, which has no corresponding part. Now, this quantity is entirely known. For, since $e^n = 1$, we have $e^{\frac{n}{2}} = e^{-\frac{n}{2}} = \pm 1$; but e has been so assumed, that none of its powers with indices less than n are equal to unit; and, therefore, $e^{-\frac{n}{2}} = -1$, and $e^{-\frac{n}{2}\varrho} = (-1)^{\varrho}$. Again, by equation (3), $f\left(o, \frac{n}{2}\right) = \pm k$; wherefore we have

$$\frac{1}{n}.e^{-\frac{n}{2}\varrho}.f\left(o, \frac{n}{2}\right) = \frac{1}{n}.(-1)^{\varrho}. \times \pm k.$$

On the whole, the preceding analysis brings us to the following formulæ, which contain the solution of the problem, viz.

when n is even, by equation (5),

$$P^{\frac{n}{2}} = (1, 2).(1, 3).(1, 4)\ldots.\left(1, \frac{n}{2}\right) \times \pm k;$$

when n is odd, by equation (6),

$$P^n = (1, 2)^2.(1, 3)^2 (1, 4)^2 \ldots \left(1, \frac{n-1}{2}\right)^2.\left(1, \frac{n+1}{2}\right).k^2;$$

and by equation (2), $PP' = k^2$.

Finally, by substituting the values of $f(o, 2)$, $f(o, 3)$, &c. $f(o, -2)$, $f(o, -3)$, &c. in the expression of $\cos. a^{\varrho}\varphi$, we get

$$\cos. a^{\varrho}\varphi = -\frac{1}{2n} + \frac{k}{n}.\left\{\frac{e^{-\varrho}P}{k} + \frac{e^{\varrho}P'}{k}\right\}$$
$$+\frac{k}{n}.\left\{\frac{(-1, -2)}{k}.\left(\frac{e^{-\varrho}P}{k}\right)^2 + \frac{(1, 2)}{k}.\left(\frac{e^{\varrho}P'}{k}\right)^2\right\}$$
$$+\frac{k}{n}.\left\{\frac{(-1, -2)}{k}.\frac{(-1, -3)}{k}.\left(\frac{e^{-\varrho}P}{k}\right)^3\right.$$
$$\left.+\frac{(1, 2)}{k}.\frac{(1, 3)}{k}\left(\frac{e^{\varrho}P'}{k}\right)^3\right\}$$
$+$, &c.

the series of terms must be continued till the last index of $\frac{e^{-\varrho}P}{k}$ and $\frac{e^{\varrho}P'}{k}$ is $\frac{n-1}{2}$ when n is odd, and $\frac{n-2}{2}$ when n is even; and, in this last case, the quantity $\frac{1}{n} \times (-1)^{\varrho} \times \pm k$, must be added, prefixing to k the same sign that is given to it in the value of $P^{\frac{n}{2}}$.

The solution of the problem is thus reduced to the computation of the functions (1, 2), (1, 3), &c. which requires no more than the substitution of 1 for m, and of 2, 3, 4, &c. successively for s, in the expression of A, equation (2). The half of these functions that have negative indices are deduced from the other half, merely by changing the signs of the several indices of e, or by means of equation (4). All the cosines sought are found by substituting o, 1, 2, 3, &c. successively for ϱ. Although the function P is susceptible of n different values, represented by x, ex, e^2x, &c.; yet the same cosines are deduced from any one of these values. By this means all ambiguity is avoided with regard to the system of values that represent the cosines; but the numerical value that must be attached to each particular cosine remains quite indeterminate, because φ may equally stand for $\frac{360°}{p}$, $2 \times \frac{360°}{p}$, $3 \times \frac{360°}{p}$, &c. The adaptation of the numerical quantities to the geometrical cosines must be made out by means of their relative magnitudes; the largest number answering to the greatest cosine. But when the value of one cosine is fixed, the rest are unambiguously determined by means of their indices.

In the formula for $\cos. a^{\varrho}\varphi$ all the terms in which two quantities are combined have real values, although their forms are imaginary. But it is not difficult to transform them into equivalent quantities without the imaginary sign.

It is manifest that the functions (1, 2) and (— 1, — 2) are of this form, viz.

$$(1, 2) = A + Be + Ce^2 + De^3 \ldots + Ne^{n-1},$$
$$(-1, -2) = A + Be^{-1} + Ce^{-2} + De^{-3} \ldots + Ne^{-(n-1)},$$

A, B, C, &c. denoting given co-efficients.

But we have generally

$$e^{\lambda} = \cos. \lambda\tau + \sin. \lambda\tau\sqrt{-1},$$
$$e^{-\lambda} = \cos. \lambda\tau - \sin. \lambda\tau\sqrt{-1}:$$

wherefore, by combining the two expressions of (1, 2) and (— 1, — 2), we shall readily get

$$\frac{(1, 2) + (-1, -2)}{2} = A + B\cos. \tau + C\cos. 2\tau +, \&c.$$
$$\frac{(1, 2) - (-1, -2)}{2} = \qquad B\sin. \tau + C\sin. 2\tau +, \&c.$$

But, on account of equation (4), we may assume

$$(1, 2) = k(\cos. \beta + \sin. \beta\sqrt{-1}),$$
$$(-1, -2) = k(\cos. \beta - \sin. \beta\sqrt{-1});$$

and, by substituting these values in the last expressions, we get

$$k\cos. \beta = A + B\cos. \tau + C\cos. 2\tau +, \&c.$$
$$k\sin. \beta = \qquad B\sin. \tau + C\sin. 2\tau +, \&c.$$

by which means the arc β is determined without ambiguity, since both its sine and cosine are ascertained. In like manner are determined the several arcs in the formulæ

$$(1, 3) = k(\cos. \beta' + \sin. \beta'\sqrt{-1}),$$
$$(-1, -3) = k(\cos. \beta' - \sin. \beta'\sqrt{-1}),$$
$$(1, 4) = k(\cos. \beta'' + \sin. \beta''\sqrt{-1}),$$
$$(-1, -4) = k(\cos. \beta'' - \sin. \beta''\sqrt{-1}),$$
&c.

Again, because $PP' = k^2$, we may assume

$$P = k(\cos. w + \sin. w\sqrt{-1}),$$
$$P' - k(\cos. w - \sin. w\sqrt{-1}),$$

And if these values, and the similar values of the functions (1, 2), (1, 3), &c. be substituted in the value of $P^{\frac{n}{2}}$, we shall readily deduce, when n is an even number,

$$\frac{n}{2} \cdot w = \beta + \beta' + \beta'' +, \&c.$$

When n is an odd number, we must separate the function $\left(1, \frac{n+1}{2}\right)$ from the rest, by supposing $\left(1, \frac{n+1}{2}\right) = k$ $(\cos.\gamma + \sin.\gamma\sqrt{-1})$: and then, by means of equation (6), we shall easily obtain

$$nw = 2(\beta + \beta' + \beta'' +, \&c.) + \gamma.$$

The two last formulæ determine the arc w; and we likewise have

$$\frac{e^{-\varrho}P}{k} = \cos.(w - \varrho\tau) + \sin.(w - \varrho\tau)\sqrt{-1},$$

$$\frac{e^{\varrho}P'}{k} = \cos.(w - \varrho\tau) - \sin.(w - \varrho\tau)\sqrt{-1};$$

and, by putting $w^{(\varrho)} = w - \varrho\tau$,

$$\frac{e^{-\varrho}P}{k} = \cos. w^{(\varrho)} + \sin. w^{(\varrho)}\sqrt{-1},$$

$$\frac{e^{\varrho}P}{k} = \cos. w^{(\varrho)} - \sin. w^{(\varrho)}\sqrt{-1}.$$

Finally, by substituting the different values exhibited above in the formula for $\cos. a^{\varrho}\varphi$, we shall get

$$\begin{aligned}\cos. a^{\varrho}\varphi = -\frac{1}{2n} &+ \frac{2k}{n}.\cos. w^{(\varrho)} \\ &+ \frac{2k}{n}.\cos.(2w^{\varrho} - \beta) \\ &+ \frac{2k}{n}.\cos.(3w^{(\varrho)} - \beta - \beta') \\ &+ \frac{2k}{n}.\cos.(4w^{(\varrho)} - \beta - \beta' - \beta'') \\ &\&c.\end{aligned}$$

the series of terms being continued till all the arcs β, β', β'', &c. are taken in when n is odd; and till they are all taken in except the last when n is even, in which case also the quantity $(-1)^{\varrho}.\frac{k}{n}$ must be added.

By the preceding analysis the division of the circle into p equal parts is accomplished, when p is a prime number, by dividing a given arc into n or $\frac{p-1}{2}$ equal parts. And this conclusion agrees with the general proposition of M. Gauss. For the nth part of a given arc is found by bisecting as often as n is divisible by 2, trisecting as often as it is divisible by 3, and so on. When n is a power of two, as in the case of the polygon of 17 sides, the solution is effected by repeated bisections, and thus comes under the elementary geometry. Supposing the division of the circle to be accomplished, we must further resolve the quadratic equation

$$x + \frac{1}{x} = 2\cos..\frac{\lambda \times 360°}{p},$$

in order to find the roots of the binomial equation $x^p - 1 = 0$.

The following examples are subjoined for the sake of illustrating the method of calculation. And, in the first place, we may take the case of $p = 11$ equivalent to finding the roots of the equation $x^{11} - 1 = 0$, which was first solved by Vandermonde, and has been considered both by Lagrange and Legendre. Here, $n = 5$; $k = \frac{1}{2}\sqrt{11}$; $\tau = \frac{360°}{5} = 72°$; $e = \cos.\tau + \sin.\tau\sqrt{-1}$; and, as 2 is a primitive root of 11, we may suppose $a = 2$. In order to find the numbers $h(\lambda)$ and $h'(\lambda)$, write down the series 1, 2, 3, &c. as far as n or 5; and, above each number, write the power of a equal to it when the multiples of 11 are rejected, taking always the least remainder, whether positive or negative: thus,

$$\begin{matrix} a^0 & a^1 & a^3 & a^2 & a^4 \\ 1 & 2 & 3 & 4 & 5. \end{matrix}$$

In this arrangement of the powers of a, it is evident that, λ denoting any index, $h(\lambda)$ is the next on the right hand, and $h'(\lambda)$ the next on the left hand: we have, therefore,

$$i = 1,$$

$$\begin{aligned} h(1) &= 3, & h'(1) &= 0, \\ h(2) &= 4, & h'(2) &= 3, \\ h(3) &= 2, & h'(3) &= 1, \\ h(4) &= 4, & h'(4) &= 2. \end{aligned}$$

Now, substitute these numbers in the expression of A, equation (2), and likewise put $m = 1$; then

$$\begin{aligned} A = \frac{1}{2}e^{-s} &+ \frac{1}{2}e^{1-3s} + \frac{1}{2}e \\ &+ \frac{1}{2}e^{2-4s} + \frac{1}{2}e^{2-3s} \\ &+ \frac{1}{2}e^{3-2s} + \frac{1}{2}e^{3-s} \\ &+ \frac{1}{2}e^{4-4s} + \frac{1}{2}e^{4-2s}. \end{aligned}$$

In order to find (1, 2) and (1, 3), we have only to substitute 2 and 3 for s in the expression of A; hence

$$(1, 2) = 1 + 2e + \frac{1}{2}e^3 + e^4,$$

$$(1, 3) = 1 + \frac{1}{2}e + 2e^2 + e^3;$$

which values will, in this case, be rendered somewhat more simple by combining them with the equation $0 = 1 + e + e^2 + e^3 + e^4$: and thus we get

$$(1, 2) = e - e^2 - \frac{1}{2}e^3 = m,$$

$$(1, 3) = e^2 - e^4 - \frac{1}{2}e = \mu.$$

The functions $(-1, -2)$ and $(-1, -3)$ are found by subtracting the indices of e in the values of (1, 2) and (1, 3) from 5, which is equivalent to changing the signs of the indices; therefore

$$(-1, -2) = e^4 - e^3 - \frac{1}{2}e^2 = m,$$

$$(-1, -3) = e^3 - e - \frac{1}{2}e^4 = \mu'.$$

And it will be found, by actually multiplying, that

$$mm' = k^2 = \frac{11}{4} \text{ and } \mu\mu' = k^2 = \frac{11}{4}.$$

These values being found, we have, according to the foregoing method,

$$P^5 = (1, 2)^2 \cdot (1, 3) \cdot k^2 = m^2\,\mu \cdot k^2,$$

$$P'^5 = \frac{k^{10}}{P^5} = (-1, -2)^2 . (-1, -3) . k^2 = m'^2\,\mu' . k^2;$$

and hence $\frac{P}{k} = \frac{1}{k}(m^2\mu . k^2)^{\frac{1}{5}}$,

$$\frac{P'}{k} = \frac{1}{k}(m'^2\mu' . k^2)^{\frac{1}{5}},$$

$$\frac{m'}{k} \cdot \frac{P^2}{k^2} = \frac{1}{k}(m'\mu^2 . k^2)^{\frac{1}{5}},$$

$$\frac{m}{k} \cdot \frac{P'^2}{k^2} = \frac{1}{k}(m\mu'^2 . k^2)^{\frac{1}{5}};$$

wherefore we have

$$\cos.\, a^{\varrho}\varphi = -\frac{1}{10} + \frac{e^{-\varrho}}{5} \,.\, (m^2\mu \,.\, k^2)^{\frac{1}{5}} + \frac{e^{\varrho}}{5} \,.\, (m'^2\mu' \,.\, k^2)^{\frac{1}{5}}$$

$$+\frac{e^{-2\varrho}}{5} \,.\, (m'\mu^2 \,.\, k^2)^{\frac{1}{5}} + \frac{e^{2\varrho}}{5} \,.\, (m\mu'^2 \,.\, k^2)^{\frac{1}{5}}\,.$$

If, in this expression, we make $\varrho=0$, and substitute the numerical values of k^2, and of e and its powers, in the quantities under the radical sign, the result will coincide with the formula of Vandermonde, and with the calculation of Lagrange.

The expression just found being imaginary, if it be required to reduce it to a form fit for calculation, we must begin with substituting the values of e and its powers in m and μ: then

$$m=(\cos.\, \tau - \cos.\, 2\tau - \frac{1}{2}\cos.\, 3\tau)$$

$$+(\sin.\, \tau - \sin.\, 2\tau - \frac{1}{2}\sin.\, 3\tau) \,.\, \sqrt{-1},$$

$$\mu=(\cos.\, 2\tau - \cos.\, 4\tau - \frac{1}{2}\cos.\, \tau)$$

$$+ (\sin.\, 2\tau - \sin.\, 4\tau - \frac{1}{2}\sin.\, \tau) \,.\, \sqrt{-1}.$$

Now, $\cos.\, \tau = \cos.\, 4\tau = -\frac{1}{4}+\frac{1}{4}\sqrt{5}$, and $\cos.\, 2\tau = \cos.\, 3\tau = -\frac{1}{4}-\frac{1}{4}\sqrt{5}$; also $\sin.\, \tau = -\sin.\, 4\tau$, and $\sin.\, 2\tau = -\sin.\, 3\tau$: wherefore

$$m=(\cos.\, \tau - \frac{3}{2}\cos.\, 2\tau) + (\sin.\, \tau - \frac{1}{2}\sin.\, 2\tau) \,.\, \sqrt{-1},$$

$$\mu=(\cos.\, 2\tau - \frac{3}{2}\cos.\, \tau) + (\sin.\, 2\tau + \frac{1}{2}\sin.\, \tau) \,.\, \sqrt{-1}.$$

Again,

$$m=k\,(\cos.\, \beta + \sin.\, \beta \,.\, \sqrt{-1}),$$
$$\mu=k\,(\cos.\, \gamma + \sin.\, \gamma\, \sqrt{-1});$$

consequently

$$\cos.\, \beta = \frac{1}{k}(\cos.\, \tau - \frac{3}{2}\cos.\, 2\tau) = \frac{1+5\sqrt{5}}{4\sqrt{11}},$$

$$\sin.\, \beta = \frac{1}{k}(\sin.\, \tau - \frac{1}{2}\sin.\, 2\tau),$$

$$\cos.\, \gamma = \frac{1}{k}(\cos.\, 2\tau - \frac{3}{2}\cos.\, \tau) = \frac{-1+5\sqrt{5}}{4\sqrt{11}},$$

$$\sin.\, \gamma = \frac{1}{k}(\sin.\, 2\tau + \frac{1}{2}\sin.\, \tau).$$

Hence

$$\beta = 23^\circ\ 20'\ 46'',$$
$$\gamma = 140\ \ 7\ \ 6\tfrac{1}{2},$$
$$5\omega = 2\beta+\gamma = 186\ \ 48\ \ 38\tfrac{1}{2},$$
$$\omega = 37\ \ 21\ \ 44,$$

$$\omega^{(\varrho)} = \omega - \varrho \times 72^\circ:$$

$$\cos.\, a_{\varrho}\varphi = -\frac{1}{10} + \frac{\sqrt{11}}{5} \,.\, \left\{\cos.\, \omega^{(\varrho)} + \cos.\, (2\omega^{\varrho} - \beta)\right\}.$$

By making ϱ successively equal to 0, 1, 2, 3, 4, the formula will give all the ten cosines of a polygon of eleven sides inscribed in a circle; because $\cos.\, \frac{360^\circ}{11} = \cos.\, 10 \,.\, \frac{360^\circ}{11}$, $\cos.\, 2 \,.\, \frac{360^\circ}{11} = \cos.\, 9 \,.\, \frac{360^\circ}{11}$, &c. It determines also the order of the arcs to which the numerical quantities belong; so that when the value of one cosine is fixed, the values of all the rest are likewise ascertained.

This last formula coincides with the calculation of Legendre.

The next example shall be the case of $p=17$. Then, $n=8$, $k=\frac{1}{2}\sqrt{17}$, $\tau=\frac{360^\circ}{8}=45^\circ$, and $e=\cos.\, \tau + \sin.\, \tau\sqrt{-1}$; and, 3 being one of the primitive roots of 17, we may take $a=3$. Now, arranging the powers of a as in the last example, we have

$$a^0,\ a^6,\ a^1\ a^4,\ a^5,\ a^7,\ a^3,\ a^2$$
$$1,\ 2,\ 3,\ 4,\ 5,\ 6,\ 7,\ 8:$$

and hence,

$$i=6$$

$h(1)=4$, $h'(1)=6$,
$h(2)=2$, $h'(2)=3$,
$h(3)=2$, $h'(3)=7$,
$h(4)=5$, $h'(4)=1$,
$h(5)=7$, $h'(5)=4$,
$h(6)=1$, $h'(6)=0$,
$h(7)=3$, $h'(7)=5$.

By substituting these numbers in the expression of A, and likewise by putting $m=1$, we get

$$\mathrm{A}=\frac{1}{2}e^{-6s}+\frac{1}{2}e^{1-4s}+\frac{1}{2}e^{1-6s}$$
$$+\frac{1}{2}e^{2-2s}+\frac{1}{2}e^{2-3s}$$
$$+\frac{1}{2}e^{3-2s}+\frac{1}{2}e^{3-7s}$$
$$+\frac{1}{2}e^{4-5s}+\frac{1}{2}e^{4-s}$$
$$+\frac{1}{2}e^{5-7s}+\frac{1}{2}e^{5-4s}$$
$$+\frac{1}{2}e^{6-s}+\frac{1}{2}e^{6}$$
$$+\frac{1}{2}e^{7-3s}+\frac{1}{2}e^{7-5s}.$$

In order to have the functions (1, 2), (1, 3), (1, 4), nothing more is necessary than to substitute 2, 3, 4 for s in the expression of A: then, observing that $e+e^5=0$, $e^2+e^6=0$, $e^3+e^7=0$, we readily get

$$(1,\ 2) = \frac{3}{2}e^4+e^7+e^5 = -\frac{3}{2}-\sqrt{-2} = -m,$$

$$(1,\ 3) = 1+\frac{1}{2}e^4+2e^6 = \frac{1}{2}-2\sqrt{-1} = n,$$

$$(1,\ 4) = \frac{3}{2}+e+e^3 = \frac{3}{2}+\sqrt{-2} = m:$$

and hence

$$(-1,\ -2) = \frac{3}{2}e^4+e+e^3 = -\frac{3}{2}+\sqrt{-2} = -m',$$

$$(-1,\ -3) = 1+\frac{1}{2}e^4+2e^2 = \frac{1}{2}+2\sqrt{-1} = n',$$

$$(-1,\ -4) = \frac{3}{2}+e^7+e^5 = \frac{3}{2}-\sqrt{-2} = m'.$$

These values being found, we next have

$$\mathrm{P}^4 = (1,\ 2) \,.\, (1,\ 3) \,.\, (1,\ 4) \,.\, f(0,\ 4);$$
$$f(0,\ 4) = \pm k;$$

therefore, making $f(0,\ 4) = -k$,

$$\mathrm{P}^4 = m^2nk,$$

$$\mathrm{P}'^4 = \frac{k^8}{\mathrm{P}^4} = m'^2n'k;$$

and hence

$$\frac{1}{k}\mathrm{P} = \frac{1}{k}(m^2nk)^{\frac{1}{4}};\ \frac{1}{k}\,.\,\mathrm{P}' = \frac{1}{k}(m'^2n'k)^{\frac{1}{4}};$$

$$-\frac{m'}{k}\cdot\frac{\mathrm{P}^2}{k^2}=-\frac{1}{k}\cdot\sqrt{nk}\,;\ -\frac{m}{k}\cdot\frac{\mathrm{P}^2}{k^2}=-\frac{1}{k}\sqrt{n'k}\,;$$

$$-\frac{m'}{k}\cdot\frac{n'\mathrm{P}^3}{kk^3}\cdot=-\frac{1}{k}(m^2n'k)^{\frac{1}{4}}\,;\ -\frac{m}{k}\cdot\frac{n}{k}\cdot\frac{\mathrm{P}'^3}{k^3}$$

$$=-\frac{1}{k}(m'^2nk)^{\frac{1}{4}}\,;$$

$$\cos.\,a^{\varrho}\varphi=-\frac{1}{16}-(-1)^{\varrho}\cdot\frac{\sqrt{17}}{16}$$

$$+\frac{1}{8}\cdot\left\{e^{-\varrho}(m^2nk)^{\frac{1}{4}}+e^{\varrho}\,(m'^2n'k)^{\frac{1}{4}}\right\}$$

$$-\frac{1}{8}\cdot\left\{e^{-2\varrho}(nk)^{\frac{1}{2}}+e^{2\varrho}\,(n'k)^{\frac{1}{2}}\right\}$$

$$-\frac{1}{8}\left\{e^{-3\varrho}\,(m^2n'k)^{\frac{1}{4}}+e^{3\varrho}\,(m'^2nk)^{\frac{1}{4}}\right\}.$$

In order to reduce this expression, we shall put

$$\varphi(\varrho)=e^{-2\varrho}\sqrt{nk}+e^{2\varrho}\sqrt{n'k},$$

$$\Psi(\varrho)=e^{-\varrho}(m^2nk)^{\frac{1}{4}}+e^{\varrho}(m'^2n'k)^{\frac{1}{4}}$$

$$-e^{-3\varrho}\,(m^2n'k)^{\frac{1}{4}}-e^{3\varrho}(m'^2nk)^{\frac{1}{4}}.$$

And because $e^4=e^{-4}=-1$, we get $e^{6\varrho}=e^{-2\varrho}=(-1)^{\varrho}\,.\,e^{2\varrho}$, and $e^{-6\varrho}=e^{2\varrho}=(-1)^{\varrho}\,.\,e^{-2\varrho}$. Wherefore, by squaring,

$$\left\{\varphi(\varrho)\right\}^2=2k^2+(-1)^{\varrho}\,.\,k,$$

$$\left\{\Psi(\varrho)\right\}^2=4k^2-6k(-1)^{\varrho}+3\varphi(\varrho)-2k\,.\,\varphi(\varrho)\,.\,(-1)^{\varrho}.$$

Now, in the formula for cos. $a^{\varrho}\varphi$, viz. $\cos.\,a^{\varrho}\varphi=-\frac{1}{16}-(-1)^{\varrho}.\frac{\sqrt{17}}{16}-\frac{1}{8}\,\varphi(\varrho)-\frac{1}{8}\Psi(\varrho)$, if we change ϱ into $\varrho+4$, no alteration will be produced, except that $\Psi(\varrho)$ will change its sign; for it is obvious that

$$\Psi(\varrho+4)=e^4\,.\,\Psi(\varrho)=-\Psi(\varrho).$$

Hence we readily deduce these two equations, viz.

$$\frac{1}{2}(\cos.\,a^{\varrho}\varphi+\cos.\,a^{\varrho+4}\varphi)=-\frac{1}{16}-(-1)^{\varrho}\,.\,\frac{\sqrt{17}}{16}-\frac{1}{8}\varphi(\varrho),$$

$$\frac{1}{4}(\cos.\,a^{\varrho}\varphi-\cos.\,a^{\varrho+4}\varphi)^2=\frac{1}{64}\times\left\{\Psi(\varrho)\right\}^2.$$

If we suppose $\varrho=0$, then

$$\left\{\varphi(0)\right\}^2=2k^2+k\,;$$

wherefore

$$\frac{1}{2}(\cos.\,\varphi+\cos.\,a^4\varphi)=-\frac{1}{16}-\frac{\sqrt{17}}{16}-\frac{1}{8}\sqrt{2k^2+k},$$

$$\frac{1}{4}(\cos.\,\varphi-\cos.\,a^4\varphi)^2=\frac{1}{64}\cdot\left\{4k^2-6k-(2k-3)\times\sqrt{2k^2+k}\right\}.$$

And, when $\varrho=2$, then

$$\varphi(2)=e^4\,.\,\varphi(0)=-\varphi(0)\,;$$

wherefore

$$\frac{1}{2}(\cos.\,a^2\varphi+\cos.\,a^6\varphi)=-\frac{1}{16}-\frac{\sqrt{17}}{16}+\frac{1}{8}\sqrt{2k^2+k},$$

$$\frac{1}{4}(\cos.\,a^2-\cos.\,a^6\varphi)^2=\frac{1}{64}\cdot\left\{4k^2-6k+(2k-3)\times\sqrt{2k^2+k}\right\}.$$

Next, suppose $\varrho=1$, then

$$\left\{\varphi(1)\right\}^2=2k^2-k\,;$$

wherefore

$$\frac{1}{2}(\cos.\,a\varphi+\cos.\,a^5\varphi)=-\frac{1}{16}+\frac{\sqrt{17}}{16}+\frac{1}{8}\sqrt{2k^2-k},$$

$$\frac{1}{4}(\cos.\,a\varphi-\cos.\,a^5\varphi)^2=\frac{1}{64}\cdot\left\{4k^2+6k+(2k+3)\sqrt{2k^2-k}\right\}:$$

and, finally, making $\varrho=3$, we get

$$\varphi(3)=e^4\times\varphi(1)=-\varphi(1)\,;$$

wherefore

$$\frac{1}{2}(\cos.\,a^3\varphi+\cos.\,a^7\varphi)=-\frac{1}{16}+\frac{\sqrt{17}}{16}-\frac{1}{8}\sqrt{2k^2-k},$$

$$\frac{1}{4}(\cos.\,a^3\varphi-\cos.\,a^7\varphi)^2+\frac{1}{64}\cdot\left\{4k^2+6k-(2k+3)\sqrt{2k^2-k}\right\}.$$

These formulæ enable us to find the numerical values of all the cosines sought; observing always that φ is indeterminate, and varies with the primitive root from which the solution is deduced. (K. K.)

EQUATOR, or ÆQUATOR, in *Astronomy* and *Geography*, a great circle of the sphere, equally distant from the two poles of the world, or having the same poles with those of the world. It is called the *equator*, because when the sun is in it the days and nights are *equal;* whence also it is denominated the *equinoctial*, and, when drawn on maps and planispheres, the *equinoctial line*, or simply the *line*. Every point of the equator is distant a quadrant from the poles of the world; and hence it follows that the equator divides the sphere into two hemispheres, in one of which is the northern, and in the other the southern pole.

EQUERY, or ECURY, a grand stable or lodge for horses, furnished with all suitable conveniences, as stalls, manger, rack, &c. The word is formed from the French *écurie*, which signifies the same thing. Some, again, derive *écurie* from the Latin *scuria*, which not only denotes a place for beasts to be stalled in, but also a grange or barn. But a more probable derivation is from *equile*, a stable for horses, from *equus*, horse. Some think that the word *stable* properly relates only to bullocks, cows, sheep, hogs, &c. and *equery* to horses, mules, &c.

A *simple equery* is that provided for one row of horses; a *double equery* that provided for two, with a passage in the middle; or two passages, the horses being placed head to head.

Under the term equery are sometimes also comprehended the lodgings and apartments of the equeries, grooms, pages, and others.

EQUERY (*écuyer*) is also an officer who has the care and management of the horses of a king or prince.

EQUES AURATUS is used to signify a knight-bachelor, called *auratus*, because anciently none but knights might gild or beautify their armour or other habiliments of war with gold. In law this term is not used, but instead of it *miles*, and sometimes *chevalier*.

EQUESTRIA, among the Romans, a place in the theatre occupied by the equites or knights.

EQUESTRIAN (*equestris*), a term chiefly used in the phrase *equestrian statue*, which signifies a statue representing a person mounted on horseback. The word is formed from the Latin *eques*, knight or horseman, from *equus*, horse.

Equestrian Games, among the Romans, horse-races, of which there were five kinds; the *prodromus* or *plain horse-race*, the *chariot-race*, the *decursory-race* about funeral piles, the *ludi sevirales*, and the *ludi neptunales*.

EQUIANGULAR, in *Geometry*, an epithet applied to figures the angles of which are all equal; such are a square, an equilateral triangle, and the like.

EQUIDISTANT, an appellation given to things placed at equal distances from some fixed point or place to which they are referred.

EQUILATERAL, in general, something that has equal sides; as an equilateral triangle.

EQUILIBRIUM, in *Mechanics*, is when the two ends of a lever or balance hang so exactly even and level that neither ascends or descends, but both remain in a position parallel to the horizon; which is occasioned by their being both charged with an equal weight.

EQUIMULTIPLES, in *Arithmetic* and *Geometry*, are numbers or quantities multiplied by one and the same number or quantity. Hence equimultiples are always in the same ratio to each other as the simple quantities before multiplication; thus, if 6 and 8 are multiplied by 4, the equimultiples 24 and 32 will be to each other as 6 to 8.

EQUINOCTIAL, or ÆQUINOCTIAL, in *Astronomy*, a great and immoveable circle of the sphere, under which the equator moves in its diurnal motion.

The equinoctial, or æquinoctial line, is ordinarily confounded with the equator; but there is a difference, the equator being moveable and the equinoctial immoveable; the equator being drawn about the convex surface of the sphere, and the equinoctial on the concave surface of the *magnus orbis*.

Whenever the sun, in his progress through the ecliptic, comes to this circle, the days and nights are equal all over the globe; for then he rises due east and sets due west, which he never does at any other time of the year; and hence the denomination, from *æquus*, equal, and *nox*, night, *quia æquat diem nocti*.

The equinoctial, then, is the circle which the sun describes, or appears to describe, at the time of the equinoxes; that is, when the length of the day is everywhere equal to that of the night, which happens twice a year.

Equinoctial Points are the two points in which the equator and ecliptic intersect each other; the one, being in the first point of Aries, is called the *vernal point* or *equinox;* and the other, in the first point of Libra, is denominated the *autumnal point* or *equinox*.

Equinoctial Dial, a dial, the plane of which is parallel to that of the equinoctial. See DIAL.

EQUINOX, or ÆQUINOX, in *Astronomy*, the time when the sun enters one of the equinoctial points.

The equinoxes happen when the sun is in the equinoctial circle, and the days are equal to the nights throughout the world, which is the case twice a year; namely, about the 20th of March and the 23d of September, the former being the vernal and the latter the autumnal equinox.

EQUIPOLLENCE, in *Logic*, is when there is an equivalence between any two or more terms or propositions; that is, when they amount to the same thing, though they express it differently. Such terms or propositions are said to be *equipollent*.

EQUIRIA, in *Antiquity*, a festival instituted by Romulus, and celebrated on the 27th of February, in honour of Mars. There were horse-races at this festival.

EQUITES, an order of men in the commonwealth of Rome, to which we can furnish no exact parallel in modern times. They seem, indeed, to have resembled in some degree the gentry of England; with this difference, however, that they enjoyed peculiar privileges, and were more of a separate caste than any body of men which can now be pointed out. Their origin goes back to the earliest times of Roman history, though we can perceive, even from the legendary statements of Livy and Dionysius, that their constitution and mode of selection had been changed in the course of ages. During the reign of the kings they evidently appear to have been of noble birth, the younger branches of patrician families. This we may infer from the statement of Polybius (vi. 20), when he says that the knights *now* are chosen according to fortune, evidently intimating that their selection had depended on a different principle at a previous period. Romulus is said to have divided them into three centuries; and the very names of Ramnenses, Titienses, and Luceres, by which he designated them, point out distinctly their high origin. Both Tullus Hostilius and Tarquinius added to their number; but it was Servius Tullius (576 B. C.) who first organised them into a distinct body, and compelled the state to contribute annually to their maintenance. It is difficult to perceive in what way we are to explain the statement of Livy (i. 43), that the sum of ten thousand pounds of brass was given to each for the purchase of a horse; an enormous sum, when compared with that at which oxen and sheep were rated in the table of penalties. They were bound of course to be provided with a noble steed, and may have been obliged to replace it if it fell from any casualty in war. The accoutrements, too, and a slave to take charge of it, were possibly all included in this large sum. But whether, when the censor ordered the knight to sell his horse, it was the intention that the outfit money should be refunded to the state, we have now no means of determining. Livy tells us also that a tax was imposed on each *vidua*, of two thousand pounds of brass, to maintain a knight's horse. This certainly sounds very strange; for it seems inconceivable that there should have been such a large number of rich widows; and even though we understand by the word *vidua* every single woman, maiden as well as widow, we do not think that we thereby get out of the difficulty.

As early as 400 B. C. we find that a certain fortune was required to enable a man to be raised to the rank of eques. In that year, at the siege of Veii, we are told that those who possessed the requisite fortune, but to whom horses had not been assigned, offered to provide these at their own expense. This proposal was accepted; and then it was, according to Livy (v. 7), that they first received regular pay. In 303 B. C. the censors Q. Fabius and P. Decius established a law, by which it was ordained that every fifth year a procession of the equites should take place, and that those who had misconducted themselves should be degraded from their rank. They now evidently became a very powerful body in the state; yet in 186 B. C. we find it allowed as a reward to P. Æbutius, that the censor should not assign him a public horse, and thereby compel him to serve as an eques against his will. This proves that the duties must have been burdensome, and regarded by many with distaste. In the later times of the republic they increased in power and consequence, when the judicial functions were transferred from the senate to the body of equites by the Sempronian law, passed by C. Gracchus about 123 B. C.; and a short time afterwards they became the farmers of the public revenues, which enabled them to amass immense riches. Sylla deprived them of their judicial powers; but they now possessed too much influence in the state to be excluded from the higher and more dignified offices. After his death they were again admitted to their former power, which, however, they shared with the senate.

Towards the end of the republic, and under the emperors, the fortune requisite for an eques seems to have been four hundred sestertia, equal to about L.3229 of our money; and even at this time knights' horses were furnished by the state, as we find by ancient inscriptions of that period. (Gruter. *Inscrip.* 404.)

EQUITY, in a general sense, the virtue of treating other men according to reason and justice, or as we would be treated ourselves when we understand aright what is our due.

EQUITY, in jurisprudence, is defined to be a correction or qualification of the law, generally made in that part in which it either fails or is too severe. It likewise signifies the extension of the words of the law to cases unexpressed, yet having the same reason; so that where one thing is enacted by statute, all other things are enacted which are of the same degree.

EQUITY, in *Mythology*, sometimes confounded with *Justice*, a goddess amongst the Greeks and Romans, represented with a sword in the one hand and a balance in the other.

EQUIVALENT is understood of something that is equal in value, force, or effect, to another.

EQUIVALENT Terms, are where several words which differ in sound have yet one and the same signification; as *everybody was there*, and *nobody was absent; nihil non*, and *omne.*

EQUIVOCAL TERMS or WORDS, among logicians, are those which have a doubtful or double meaning.

EQUIVOCATION, the using a term or expression which has a double signification. Equivocations are expedients to avoid telling the truth, yet without telling a direct falsehood. Some of the fathers are great patrons of equivocations and mental reservations, and hold that the use of such shifts and ambiguities is in many cases allowable.

EQUULEUS, or ECCULEUS, in *Antiquity*, a kind of rack used for extorting a confession. At first it was chiefly practised on slaves, but was afterwards made use of against the Christians.

The equuleus was made of wood, with holes at certain distances, and provided with a screw, by means of which the criminal was stretched to the third, and sometimes to the fourth or fifth hole, while his arms and legs were fastened on the equuleus with cords, and thus hoisted aloft and extended in such a manner that all his bones were dislocated. In this state red-hot plates were applied to his body, and he was goaded in the sides with an instrument called an *ungula.*

EQUULEUS, EQUICULUS, and *EQUUS Minor*, the horse's head, in *Astronomy*, a constellation of the northern hemisphere.

ERA, in *Chronology*. See CHRONOLOGY.

ERAMNOO, an island at the entrance of the Gulf of Cutch, on the western coast of India, containing a town of the same name. Long. 68. 40. E. Lat. 22. 32. N.

ERANARCHA, a public officer among the ancient Greeks, whose business it was to preside over and direct the alms and provisions allotted for the poor. Cornelius Nepos, in his Life of Epaminondas, describes the office thus: When any person was reduced to poverty, taken captive, or had a daughter to marry, which he could not effect for want of money, the eranarcha called an assembly of friends and neighbours, and taxed each according to his means and estate, in order to contribute towards the relief of such person or persons.

ERASISTRATUS, a physician of Julis, a town of the island of Ceos, now Zea, off Cape Sunium, in Attica, who seems to have flourished from about 300 to 258 B. C. He was grandson of Aristotle, his mother being daughter of that philosopher. He seems to have been in high favour at the court of Seleucus Nicanor, whose son Antiochus he is said to have recovered from a dangerous illness in a somewhat extraordinary manner. Antiochus was violently enamoured of his mother-in-law Stratonice, but seeing no prospect of honourably succeeding in his desires, he determined to rid himself of life. His physician Erasistratus easily discovered that his distemper was love, but found it difficult to conjecture who was the object. By close observation however he soon perceived that Stratonice was the cause of his illness; and having informed his father, that monarch was so fond of his son that he allowed him to marry her.

In his old age he renounced the practice of medicine, and, retiring to Alexandria, devoted himself more particularly to the study of anatomy. His description of the brain and nerves is said to have been far more correct than that of any of his predecessors. He was the founder of a school of medicine, which flourished long at Smyrna, and the numerous disciples of which, under the name of Erasistei, continued to exist till the time of Galen, upwards of 400 years. He is mentioned in several passages of the ancient authors Suidas; Strabó, x. 486; Plutarch, *Demetr.* 38; Appian. *Syr.* 59.

ERASMUS, DESIDERIUS, was born at Roterdam on the 28th of October 1467.[1] His father, who bore the name of Gerard, was an inhabitant of Tergou; his mother, named Margaret, was the daughter of Peter, a physician of Sevenbergen. He had an elder brother, called Peter, but their parents were never married, though a promise of marriage is said to have preceded their intercourse. The brothers of Gerard, who was a young man of wit and gaiety, endeavoured to secure his patrimony by compelling him to become an ecclesiastic. Finding himself very uncomfortable in his own country, he went to Rome, where he employed himself in transcribing ancient authors; for the recent invention of printing had not entirely superseded this more slow and expensive method of multiplying copies of books. In the mean time, his relations sent him a false account of Margaret's death; and his grief for her supposed loss led him to adopt a resolution to which he could not be impelled by their importunities. Having taken orders, he returned to Holland, and found that she was still alive; but he could not now fulfil his promise of marrying her, and she never would marry another, nor did she continue to cohabit with him after he became a priest. He did not neglect the education of a son who was destined to reflect so much lustre on the age and nation to which he belonged. The boy was sent to school when he was only four years old; and, when he was still very young, his musical voice procured him a place among the choiristers in the cathedral church of Utrecht. At the age of nine he was removed to the school of Deventer, where his master was Alexander Hegius, and one of his school-fellows was Adrianus Florentius, who continued to be his friend when he was long afterwards elevated to the papal chair, under the name of Adrian the Sixth. At this early period, he exhibited uncommon powers of memory; and it has been said, perhaps with some degree of exaggeration, that he could repeat all Terence and Horace. His affectionate mother, who had likewise fixed her residence at Deventer, died of the plague when he was about thirteen; and his father, deeply affected with her loss, speedily followed her to the grave. They had both of them attained the age of about forty.

Gerard had recommended his hopeful son to the care of

[1] Bayle, Dictionaire Historique et Critique, tom. ii. p. 1091. Several biographers refer the birth of Erasmus to the year 1465; but the inscription of his statue at Roterdam assigns the date of 1467.

Peter Winckel, master of the school of Gouda, and to that of other two guardians, but they all seem to have been alike unworthy of such a trust; for with the view of dividing his slender patrimony among themselves, they agreed to urge upon him the necessity of embracing the monastic state. They accordingly compelled him to betake himself to a convent of friars at Bois le Duc in Brabant, where, as he has himself stated, he lost three years of his existence. No artifice or persuasion could at first induce him to become a friar, nor did any length of time subdue his utter repugnance to a monastic life. Even at this early period, as has been well remarked, he could discern that religion was the thing least regarded in religious houses. He was afterwards placed in the convent of Sion near Delft; and having next been removed to that of Stein near Tergou, he reluctantly submitted to pass his year of probation, and to take the vows as a canon regular of St Augustin. His brother, who had likewise been devoted to the monastic profession, made an abrupt retreat from his convent, and led a profligate and dissolute life; but Erasmus, though he also quitted his monastic state, to which, as Du Pin observes, "he had no inward vocation," conducted himself with sobriety, and prosecuted his studies with great assiduity. In 1490 he left the monastery to reside in the household of Henry de Bergues, bishop of Cambray; and in 1492 he was ordained priest by the bishop of Utrecht. He had quitted the convent with the consent of the bishop, of the prior, and of the general of the order. He wore the habit as long as he conveniently could; but when he resided in Italy he was obliged to lay it aside, on account of its resemblance to the dress of those who attended persons infected with the plague. From Julius the Second he obtained permission to wear it or not, according to his own convenience, but on condition of still bearing some mark of his order; and from the same pope, or from his successor Leo the Tenth, he obtained an absolution from his monastic vows. For the name of Gerardi he had substituted that of Erasmus, as bearing a more classical form, with the same signification. This name is of a Greek origin, though its proper form is Erasmius; and, prefixing a Latin name of similar import, he adopted the appellation of Desiderius Erasmus, instead of Gerard Gerardi.

In the year 1496 he was prosecuting his studies in the university of Paris, where he became a member of the College of Montaigu, and was led to contract a friendship with our learned countryman Hector Boyce, afterwards principal of King's College, Aberdeen. The bishop of Cambray, who was more liberal of his promises than of his money, had undertaken to assist him with a small pension; but as he excited hopes which were never realized, Erasmus was left to the usual expedients of a scholar placed in such circumstances. He laboured very diligently to increase his own stock of learning, and endeavoured to earn his subsistence by taking private pupils: thus he gradually established a high reputation, and secured the friendship of individuals distinguished by their rank and influence, as well as by their talents and learning. One of his pupils was Lord Montjoy, in whom he found a steady friend, and who afterwards bestowed upon him an annual pension of a hundred crowns. It was apparently through his connexion with this young nobleman that he was induced to visit England. The plague drove him from Paris in the year 1497; and after passing through the Netherlands, where he was kindly treated by the marchioness of Vere in the castle of Tornenhens, he proceeded to London and Oxford. He now formed an acquaintance with John Colet, afterwards dean of St Paul's, and with Thomas Linacre, William Grocyn, and William Latimer, three individuals who each contributed to promote among their countrymen a more general taste for the elegancies of classical literature. He is said to have resided for some time in St Mary's College, Oxford; but not long afterwards we again find him at Paris, and he likewise appears to have visited Orleans. His *Enchiridion Militis Christiani* he had begun in 1494, at the castle of Tornenhens, but it was not completed till after an interval of several years. This little book became very popular, and was translated into various languages. An English version, ascribed to Tindall, was printed by Wynkyn de Worde in 1533.[1] About the same period he was preparing one of his most elaborate works, the *Adagia*, first printed at Paris in 1500, and was strenuously applying himself to the study of the Greek language. He mentions to one of his correspondents, that as soon as he could get any money, he would first purchase books, and afterwards clothes. He had already published several of his smaller tracts, and had laid the foundation of that celebrity which long continued to increase, and which that of very few modern scholars has exceeded. He had not however secured any adequate provision; and as he lived somewhat precariously, and wandered from one place to another, he was too frequently compelled to solicit the bounty of those to whom fortune had been more propitious.

It appears from his correspondence that he was occasionally residing in Paris in 1504 and the two succeeding years. To the study of the Greek language, to which he closely applied for the space of three years, he was induced to add that of the Hebrew; but, as Dr Jortin has remarked, "he soon grew tired of the attempt, in all probability for want of proper instructors and helps; else he did things infinitely harder than it is to learn Hebrew." The necessity of taking pupils interfered with his own plans of study, and prevented him from executing some literary projects which he had now formed. In 1506 he again made his appearance in England, and is then supposed to have visited Cambridge. During the same year, he returned to Paris, and took with him the sons of J. Baptista Boeria, first physician to Henry the Seventh. He next directed his course towards Italy; and while he was prosecuting his journey on horseback, he composed a poem on the infirmities of old age, and addressed it to William Cope, another physician. Although he had not completed his fortieth year, he considered himself as already numbered with the aged. His constitution had never been vigorous; and he was subject to various distempers, which his habits of unremitting application to study did not contribute to alleviate. At an earlier period of life, he had expressed some anxiety to visit Italy, in order to take a doctor's degree; which, as he was sufficiently aware, makes one neither better nor wiser; "but it must be done," says he, "if a man would be esteemed in the world." He accordingly took the degree of D. D. in the university of Turin. Having resided about fifteen months at Bologna, when he superintended the education of Boeria's two sons, he afterwards went to Venice, and there published a third edition of his Adages. He spent a winter at Padua, and repaired to Rome in the ensuing year. At Venice he contracted an acquaintance with Marcus Musurus and Scipio Carteromachus, who taught the Greek language at Padua and Bologna; and he availed himself of so favourable an opportunity of obtaining a solution of some of the difficulties which had occurred to him in the explication of Greek proverbs. It was at this period that he became the tutor of Alexander Stewart, a natural son of James the Fourth, by Margaret the daughter of Archibald Boyd of Bonshaw. His pupil, who was a youth of an amiable disposition and of promising talents, had been sent to the continent under the direction of Sir Thomas Halkerton, and, having travelled through France, became a student in the university of Padua; but it was at Sienna that he studied grammar and rhetoric under Erasmus, who has left a very pleasing account of his character, and who affectionately bewailed his premature death. At a very early age, he became archbishop of St Andrews, and obtained *in commendam* the abbacy of Dunfermline and the priorship of Coldingham. To these ecclesiastical preferments he added the office of lord chancellor; but having accompanied his father in the unfortunate expedition to England, he was slain, along with other warlike churchmen, at the battle of Floddon-field, before he had completed the twentieth year of his age.[1]

---

[1] This was soon followed by another edition, printed by John Byddell, and bearing the following title: "Enchiridion Militis Christiani, whiche may be called in Englysshe the hansom Weapon of a Christen Knyght; replenyshed with many goodly and godly preceptes: made by the famous clerke Erasmus of Roterdame, and newly corrected and imprinted." Lond. 1534, 8vo. Many English translations from Erasmus are mentioned in Mr Lowndes's Bibliographer's Manual of English Literature, vol. ii. p. 673.

Erasmus experienced a gracious reception from the pope and some of the cardinals, but Rome had not sufficient attractions for a person of his disposition. We again find him in England about the beginning of the year 1510. On his arrival, he took up his abode with Thomas More, who was then a young man, and who afterwards rose to great eminence. It was at this period that he composed one of his most popular works, *Stultitiæ Laudatio*, or the Praise of Folly, which has been translated into all or most of the cultivated languages of Europe. In this lucubration, which he dedicated to his friend More, he treated the pope and the court of Rome with but little ceremony; so that, as Dr Knight has observed, "he was never after this looked upon as a true son of the church." The king, before the death of his father, had addressed a very friendly letter to Erasmus when he was in Italy, and he now received him with courtesy, although it does not appear that he ever bestowed upon him any very substantial proofs of kindness. To the king, as well as to Cardinal Wolsey, he owns himself indebted, not for magnificent benefits, but for magnificent promises. His chief patron was William Warham, archbishop of Canterbury, and chancellor of the kingdom; who, besides many occasional gratuities, bestowed upon him a living worth about a hundred nobles, the rectory of Aldington, near Ashford in Kent.[2] This however he speedily resigned, reserving to himself a yearly pension of twenty pounds; to which the archbishop added an equal sum from his own purse. He was invited to Cambridge by Dr Fisher, bishop of Rochester, president of Queen's College, and chancellor of the university, who entertained him in his own house, and procured him the appointment of Lady Margaret's professor of divinity, and that of Greek professor. Of these offices however, the honour appears to have exceeded the emoluments, nor did he long continue his residence at Cambridge. In the Greek chair he was succeeded by Richard Croke, who had previously taught that language in the university of Leipzig. His treatment in England reflects no particular credit on the character of those who had the chief distribution of ecclesiastical preferments. The king, though capable of perceiving his merit, had not sufficient generosity to reward it; and the lordly churchmen reserved their best benefices for those who had other recommendations to their protection and favour. He has himself stated that if the promises made to him had been realized, he would have spent the remainder of his days in England; but having been invited to Brabant, to the court of Charles archduke of Austria, he again returned to the Netherlands, where he appears to have been residing in the beginning of the year 1514. With the honorary title of counsellor to that prince, he obtained an annual pension of two hundred florins, which, if it had been regularly paid, would have placed him in circumstances sufficiently easy. He was presented to a canonry at Courtray, but this he likewise resigned, reserving to himself a pension out of its yearly revenue.

He had for some time been laboriously employed in preparing an edition of the Greek Testament; and in the course of the same year he proceeded to Basel, for the purpose of printing it at the celebrated press of Froben. He likewise carried with him the epistles of St Jerom, illustrated with his notes, and some other books intended for publication. To the writings of this father he had devoted much attention, and, on his arrival, he was therefore gratified to find that an edition of his works had already been sent to the press. His edition of the New Testament was first printed in 1516; and other editions issued from the same press in 1519, 1522, and 1527. At Basel he now spent several months, much to his satisfaction, and was particularly gratified with the reception which he experienced from the bishop of that see. Returning to the Netherlands, he learned that Charles, who afterwards became emperor of Germany, had nominated him to a vacant bishopric in Sicily, supposing it to be at his own disposal; and, finding the right of nomination belonged to the pope, that he had solicited this preferment for Erasmus. But the recommendation, which perhaps was not very urgent, failed to produce any effect; nor did he hear of any effort to procure him a bishopric, where the patronage was more free from entanglement. In the year 1515, he appears to have paid another visit to Basel, and likewise to England. To this country he made another excursion in 1517. Of the domestic habits of the English, he has drawn a picture which now seems not a little antiquated. The plague, from which that country was scarcely ever free, and the sweating sickness, he partly ascribes to the incommodious form and bad exposition of the houses, to the filthiness of the streets, and to the sluttishness within doors. "The floors," says he, "are commonly of clay, strewed with rushes, under which lies unmolested an ancient collection of beer, grease, fragments, bones, spittle, excrements of dogs and cats, and every thing that is nasty."

Francis the First had invited him to fix his residence in France, and had promised him a benefice of a thousand livres; but of this offer he could not be induced to avail himself. He still lingered in the Netherlands; and we find him occasionally residing at Louvain, the seat of a university which was long conspicuous for the bigotry of its theologians, some of whom had appeared as his professed antagonists.[3] An event of great moment in the history of mankind was now impending. In the memorable year 1517, the reformation of religion in Germany began by Luther's bold and decided opposition to the scandalous traffic in indulgencies; one of the most corrupt practices of a most corrupt church. From this beginning, apparently trivial, arose many important events; and although Erasmus did not possess the undaunted spirit of a genuine reformer, his writings were not without considerable influence in preparing the way for those salutary changes which now began to take place. The edge of his wit and ridicule was very sharply directed against monastic ignorance and grimace, against the vain observances which were so generally substituted for real piety.[1] Many of his publications had a powerful tendency to promote a critical knowledge of the Scriptures and of ecclesiastical antiquity, and consequently were opposed, though indirectly, to the cause of popery. But he never had the courage to avow his adherence to the cause of reformation; and he himself admitted that he was not endowed with the spirit of a martyr.[2] He was sufficiently ready to condemn the heat and violence of the German reformer: but the task undertaken by Luther was not to be executed by a man of a cool and balancing disposition; and without a large portion of his unflinching impetuosity and undaunted resolution, his disputation and his preaching would, to all human appearance, have been utterly unavailing. No sudden and beneficial change in the affairs of mankind will ever be effected by those who, like Erasmus of Roterdam, keep themselves aloof from all danger, and recommend gentleness and moderation to others, when they have to contend against temporal power, fortified by inveterate prejudice, and roused by the most intense feelings of selfishness.[3] He was however very far from approving of the violent proceedings of Luther's adversaries. In the year 1520, he was consulted at Cologn by Frederick elector of Saxony, and gave a very favourable opinion of the reformer. Luther, he remarked, has been guilty of two offences; he has touched the crown of the pope and the bellies of the monks. He added, in a more serious strain, that he had justly censured many abuses and errors, which it was necessary to reform and correct; that his doctrine was essentially right, but that it had not been delivered with a proper temper, and with due moderation. Although his conduct did not fully satisfy the Lutherans, it still less satisfied the papists. The publication of his *Colloquia* did not contribute to recommend the author to the genuine sons of the Romish church: it exposed him to new accusations of laughing at indulgencies, of disregarding auricular confession, and of deriding the pious use of fish, instead of flesh, on certain appointed days. This book, the most popular of all his performances, was published at Basel: an impression, said to consist of twenty-four thousand copies, was printed in 1527 by Colinet at Paris, and dispersed with amazing rapidity. The sale was promoted by a rumour, which is supposed to have been circulated by the printer, that the work was on the point of being suppressed. During the preceding year, the theological faculty of Paris had censured it as a book in which the fasts and abstinences of the church are slighted, the suffrages of the holy virgin and the saints are derided, virginity is placed below matrimony, Christians are discouraged from a monastic life, and grammatical is preferred to theological erudition. In the year 1549 a provincial council, held at Cologn, condemned the Colloquies of Erasmus as unfit to be read in schools.

[3] Beatus Rhenanus mentions his having taught at Louvain. "Docuit Lovanii, Cantabrigiæ in Anglia, Lutetiæ etiam privatim, ubi theologiæ dedit juvenis operam." Erasmus, in his short account of his own life, has stated that he went to Louvain after he first returned from England.

The latter years of his life he spent in Switzerland, chiefly at Basel and Friburg. In the summer of 1522 he paid a visit to Constance, professing an intention of repairing to Rome, for the purpose of waiting upon his old school-fellow the new pope; but to one of his correspondents he mentions that he had fallen sick at the former city, and was deterred by rumours of war from prosecuting his journey. It is however more than probable that he had no great inclination to proceed. Adrian offered him a good deanery, which he did not think it advisable to accept; for he apparently considered it in the light of a retaining fee from the pope. In Switzerland he had many friends, and was only prevented from liking the country by the suffocating heat of the stoves, and the bad quality of the wine. Being subject to the stone and gravel, he found the new and acid beverage unsuitable to his constitution, and was obliged to procure wine from Burgundy. As he kept two servants and two horses, it may be inferred that he was enabled to live in sufficient comfort.

Ulrich von Hutten, a distinguished adherent of Luther, passing through the city of Basel in 1522, solicited an interview, which the caution of Erasmus prevented him from granting.[4] A slight of this nature was more than sufficient to rouse the vehement indignation of the German knight, who speedily discharged his spleen in a publication entitled "Ulrici ab Hutten cum Erasmo Roterodamo, Presbytero, Theologo, Expostulatio." This satirical effusion was followed by the "Spongia Erasmi adversus Aspergines Hutteni." Hutten's insolence and ferocity were blamed by Melanchthon, and by Luther himself.

In the year 1523, Adrian was succeeded in the papal chair by Clement the Seventh, who sent Erasmus an honourable epistle, accompanied with a donation of two hundred florins. After many solicitations from different quarters, he was at length induced to write against Luther, but not on a subject which involved the chief points of debate between the protestants and papists. His tract *De Libero Arbitrio* was printed in the year 1524. "Luther," says Dr Jortin, "was an admirer of Augustin, and, like the Thomists, held a physical predetermination, which entirely subverts human liberty, and which, under the pretence of making the creature dependent upon the Creator, deprives it of all active powers, so that it can do nothing without being necessarily determined by the influence of God. If there was any difference between Luther and the Thomists of the church of Rome, it was this, that Luther spake more simply and sincerely and openly than they; for he absolutely denied that there was any such thing as free-will, whilst they admitted it in words. This perhaps deceived Erasmus, who imagined that he was only disputing against Luther, whilst he was really disputing as much against Thomas Aquinas and his followers, as against the reformer. Be that as it will, Erasmus makes many good remarks against the sentiment which he opposes, and justly insists upon it, that the human will co-operates with the grace or assistance of God."[5] In 1525 Luther returned an answer, in a treatise *De Servo Arbitrio*, where his antagonist is treated with much scorn and contempt. Erasmus immediately replied in the first part of his *Hyperas-*

---

[1] Dr Robertson has remarked that "there was hardly any opinion or practice of the Romish church which Luther endeavoured to reform, but what had been previously animadverted upon by Erasmus, and had afforded him subject either of censure or raillery." (Hist. of Charles V. vol. ii. p. 142.) See likewise Archdeacon Blackburne's Confessional, p. 409. The worthy archdeacon describes Erasmus as "one of the most illustrious characters in all history."

[2] J. A. Fabricius has written a tract on the religion of Erasmus, which may be found in his *Opusculorum historico-critico-literariorum Sylloge*, p. 357. Hamb. 1738, 4to.

[3] "As the man," says Dr Paley, "who attacks a flourishing establishment writes with a halter round his neck, few ever will be found to attempt alterations but men of more spirit than prudence, of more sincerity than caution, of warm, eager, and impetuous tempers; consequently, if we are to wait for improvement till the cool, the calm, the discreet part of mankind begin it, till church governors solicit, or ministers of state propose it—I will venture to pronounce that (without His interposition with whom nothing is impossible) we may remain as we are till the renovation of all things." (Sermons and Tracts, p 43.)

[5] Jortin's Life of Erasmus, vol. i. p. 335.

pistes, and the second part appeared in the year 1527; but, upon the whole, he appears to have had no reason to congratulate himself on the issue of the controversy.

About this period, Erasmus prepared various other works. In 1525 he published "Lingua, opus novum, et hisce temporibus aptissimum." In 1528 he published, in one volume, two of the most conspicuous of his literary compositions. The first bears the title, "De recta Latini Græcique Sermonis Pronuntiatione Dialogus;" the second, "Dialogus cui titulus, Ciceronianus, sive de optimo Genere Dicendi." Both these works were printed at Basel. His dialogue on the pronunciation of the classical languages excited much attention, and occasioned much controversy.[1] The pronunciation of Greek which then prevailed, was in some countries denominated the Reuchlinian, from its having been adopted by Reuchlin, who died in the year 1521, after having been chiefly instrumental in the introduction of classical learning into Germany. It essentially coincided with the pronunciation of the modern Greeks. In the copious grammar of Scot,[2] first printed in the year 1593, we still find the same system recommended. To the letter β he assigns the name of vita, to ζ of zita, to η of ita, to θ of thita. According to this system, the vowels η, ι, υ, and the diphthongs ει, οι, have no variety of sound, but ought to be pronounced as the French pronounce the letter *i*. Thus τη, τι, τυ, τει, τοι, have one and the same sound, instead of five distinct sounds. This however is not the only peculiarity of the system. Reuchlin's mode of pronunciation was almost entirely supplanted by that of Erasmus, although several learned men have at a much more recent period endeavoured to restore the old method. In his other ingenious dialogue, the *Ciceronianus*, he ridicules some modern scholars, chiefly Italians, who studiously rejected every word or phrase which had not been sanctioned by the authority of Cicero. Of the dead and the living he speaks with his usual freedom; nor did this publication contribute to diminish the number of his enemies. It was attacked with great ferocity by Julius Cæsar Scaliger, who writes in a style by no means Ciceronian.

In the year 1529, after the mass had been abolished at Basel, he removed to Friburg, where he purchased a house, and repaired it at considerable expense. In 1533 he published at Antwerp a treatise bearing the title of "Liber de sarcienda Ecclesiæ Concordia." On the same subject, he has introduced many suggestions into his epistles; but the peace of the church was not to be patched up by any expedients which Erasmus was capable of devising. His "Ecclesiastes, sive de Ratione Concionandi," appeared in 1535; and while it was printing at Basel, he returned to that city, and there he completed his earthly pilgrimage. On the accession of Paul the Third, a design was entertained of elevating Erasmus to the rank of a cardinal; but he had never been ambitious of ecclesiastical dignities, and now the state of his health was such as to deprive all sublunary honours of their usual attractions. The pope nominated him provost of the college of canons at Deventer; but already considering himself as standing on the verge of the grave, he declined an office which he probably would not have accepted in the vigour of his life. He had left Friburg in a bad state of health, nor were his maladies alleviated by his removal to Basel. He became worse during the summer, and for about a month was afflicted with dysentery. Disregarding those formal and minute devotions which he had so much derided in the monks, he fervently implored the mercy of God through Jesus Christ; and retaining his reason unimpaired till his last moments, he calmly expired on the 12th of July 1536, when he had nearly completed the sixty-ninth year of his age. A great concourse of people attended his funeral in the cathedral church of Basel. By his will, dated in the month of February, he bequeathed handsome legacies to several of his friends, and directed the residue of his property to be distributed by his executors, in relieving the poor and the sick, in marrying young women, and in assisting young men, such as they should judge to be necessitous and deserving.

Erasmus, though somewhat low in stature, was well formed, and had an easy and genteel air, nor was he slovenly or negligent in his apparel. He had a fair complexion, with grey eyes, and, during his youth, his hair was of a pale yellow. He had a cheerful countenance, with a low voice, and a pleasing elocution. He was a steady friend, and an agreeable companion; and indeed if his conversation displayed any portion of the wit and vivacity which distinguish his writings, his society could not fail of being delightful. Ardently devoted to letters, he kept his mind uncontaminated with that avarice and ambition by which churchmen have in too many instances been secularized. In disseminating a love of elegant letters among his contemporaries, he had no small influence, and equally conspicuous were his merits as a theologian. For the lifeless formalities of scholastic theology he had little respect, and less relish; but by his labours on the New Testament, and more especially by his publication and elucidations of the original text, he gave a new impulse to the students of that age, and directed their minds to a more edifying species of knowledge. To him belongs the honour of being the earliest editor of the Greek Testament; for although the Alcala edition, inserted in the Polyglot Bible, bears the imprint of 1514, it was not published till the year 1522. Of his paraphrase of the New Testament, an English translation was printed at an early period;[3] and so high was the estimation in which it was held, that a copy of it was directed to be placed in every parish-church in the kingdom.[4] The works of the ancient fathers of the church he had studied with much assiduity. To editions of Irenæus, Chrysostom, Cyprian, Hilary, Ambrose, Jerom, Augustin, and Arnobius the younger, he contributed more or less aid; and he translated particular treatises of Origen, Athanasius, Basil, and Chrysostom. His labours likewise served to render the writings of the ancient classics more accessible. Of the Geography of Ptolomy, the Greek text was first edited by Erasmus. He published editions of Livy, Seneca, Suetonius, and other authors; and if he seldom added notes, his prefaces were considered as no small recommendation. He translated into verse the Hecuba and Iphigenia of Euripides, and into prose detached works of Galen, Plutarch, Lucian, and Libanius. The labours of Erasmus were multifarious, and his compositions are very numerous; for our scanty limits have only afforded us an opportunity of specifying the more remarkable. An ample and elegant edition of his works was published by Le Clerc, to whom we are likewise indebted for a discriminating account of the author's life and character.[1]

---

[1] Of this famous controversy a detailed account may be found in the Foreign Quarterly Review, vol. xiii. p. 60.

[2] Alexander Scot, LL. D. was a native of Scotland, but he appears to have spent the greatest part of his life in France, and to have exercised the functions of a judge at Carpentras. "Alexander Scotus Aberdonensis, magni nominis, sed majoris meriti, utriusque linguæ peritus, juris civilis scientia in paucis clarus, Carpentoractensis præfectus juri dicundo, quo in munere non minorem integritatis quam eruditionis famam acquisivit." (Dempsteri Historia Ecclesiastica Gentis Scotorum, p. 664.) We use the third edition of his *Universa Grammatica Græca*. Lugduni, 1614, 8vo. This is not the only work which Scot published.

[3] Lond. 1548-9, 2 vols. fol. The translation was executed by Miles Coverdale, Nicholas Udall, John Olde, and others. See Dr Dibdin's Typographical Antiquities, vol. iii. p. 491.

[4] Burnet's History of the Reformation, vol. ii. p. 27.

Dr Jortin has remarked that "the style of Erasmus is that of a man who had a strong memory, a natural eloquence, a lively fancy, and a ready invention, who composed with great facility and rapidity, and who did not care for the trouble of revising and correcting; who had spent all his days in reading, writing, and talking Latin; for he seems to have had no turn for modern languages, and perhaps he had almost forgotten his mother tongue. His style therefore is always unaffected, easy, copious, fluent, and clear, but not always perfectly pure, and strictly classical. He hath been censured, as a dealer in barbarisms, by persons who not only had not half of his abilities and erudition, but who did not even write Latin half so well as he. His verses are plainly the compositions of one who had much learning and good sense, and who understood prosody, or the technical part of poetry, but who had not an equal elegance of taste, and an ear for poetical numbers. So that upon the whole he is rather a versifier than a poet, and is not to be ranked amongst the Italian poets of those days, Sannazarius, Fracastorius, Vida, &c. many of whom wrote better than any of the ancients, except Lucretius, Virgil, Horace, and a few more." (x.)

ERASTIANS, a religious sect or faction which arose in England during the time of the civil wars in 1647, and were so called from their leader Thomas Erastus, whose distinguishing doctrine it was, that the church had no right to discipline, that is, no regular power to excommunicate, exclude, censure, absolve, decree, or the like.

ERATO (from *εϱαω*, *I love*), in *Mythology*, the name of one of the nine muses, who presided over amatory poetry. To this muse some have ascribed the invention of the lyre and the lute. She is represented with a garland of myrtles and roses, holding a lyre in one hand and a bow in the other, and at her side is a Cupid with his torch. There is also a Nereid of the same name.

ERATOSTHENES, the son of Aglaus, was born at Cyrene, on the northern coast of Africa, 275 B. C., and died at the advanced age of eighty, 194 B. C. We are told by Suidas that he studied under the philosopher Aristo of the island Chios, the grammarian Lysanias of Cyrene, and the poet Callimachus, whilst Strabo mentions that he received instruction from Zeno the Citian. He was invited from Athens by Ptolemy Euergetes to take charge of the celebrated library at Alexandria; and here he continued to reside under the successors of this prince, till, having lost his sight from old age, he put an end to his life by means of hunger. Though the ancients were divided in their opinions respecting his merits, there is good reason to believe that he was a man of distinguished talent, and intimately acquainted with the whole circle of science then known to the world. He was a geometer, astronomer, geographer, philosopher, grammarian, and poet, and left works behind him in each of these departments; but they have all disappeared in the lapse of ages. It is in geography that he seems to have been most distinguished; the first two books of Strabo are almost entirely occupied with an examination of his system, and a correction of some of the errors into which he had fallen respecting the western parts of Europe. We do not think that Strabo does full justice to Eratosthenes, expecting more accuracy than the state of geographical knowledge in that age would warrant. But all later writers, including Strabo himself, borrowed largely from him; and where they have ventured to correct his observations, they have only more clearly proved their ignorance of the subject. Thus Eratosthenes is nearer the truth in respect to the length of the Mediterranean from Gibraltar to Sicily than Polybius, who found fault with him. The fragments of his works have been collected and published at Oxford in one vol. 8vo; also by Seidel, Göttingen, 1789, and *Eratosthenica*, by Bernhardy, Berlin, 1822. For a list of his works, see Clinton's *Fasti Hellenici*, vol. ii. p. 513.

ERATOSTRATUS, an Ephesian who burned the famous temple of Diana, the same night on which Alexander the Great was born. This burning, as some writers have observed, was not prevented or seen by the goddess of the place, who was then present at the labour of Olympias, and at the birth of the conqueror of Persia. Eratostratus committed this crime merely to eternize his name by a memorable though infamous action.

ERBIL, a town of Persia, in the pachalic of Bagdad; the ancient Arbela, where Alexander the Great defeated Darius. It is situated on an eminence commanding an extensive plain, which abounds in grain and fruit. It is surrounded by walls, but is now a poor place, containing about 2000 or 3000 Kurds or Chaldeans. It is sixty miles east of Mosul. Long. 43. 20. E. Lat. 36. 11. N.

EREBUS, Εϱεϐος (from ערב, *night*), in *Mythology*, a term denoting darkness. According to Hesiod, Erebus was the son of Chaos and Night, and the father of the day. This was also the name of part of the *inferi* among the ancients; and a peculiar expiation was provided for those who were detained in Erebus.

Erebus was properly the gloomy region, and distinguished both from Tartarus the place of torment, and Elysium the region of bliss. According to the account given of it by Virgil, it forms the third grand division of the invisible world beyond the Styx, and comprehends several particular districts, as the *limbus infantum*, or the receptacle for infants; the *limbus* for those who had destroyed themselves; the fields of mourning, full of dark groves and woods, inhabited by those who died for love; and beyond these, an open champaign country for the accommodation of departed warriors.

ERDING, a bailiwick in the circle of the Isar, in the kingdom of Bavaria, extending over 308 square miles. It contains three large and fifty-six small towns, 262 villages, and 6632 dwelling-houses, with 28,370 inhabitants. The chief place, of the same name, is a walled town situated on the river Sempt, containing 275 houses and 1890 inhabitants, employed in various trades. Long. 11. 49. 48. E. Lat. 48. 18. 23. N.

EREKLEE, a town of Asiatic Turkey, in the province of Caramania, situated on the left bank of the river Kalys, in the centre of a fertile country. It stands in front of a hill, and, though it is of considerable size, has a mean appearance, the houses being constructed of mud, with sun-dried bricks. The gardens yield much fruit, especially pears. It is said to be the ancient Heraclea. Long. 34.

---

[1] Desiderii Erasmi Opera omnia emendatiora et auctiora. Lugd. Bat. 1703-6, 10 tom. fol. Le Clerc's account of Erasmus, chiefly derived from his letters, may be found in the *Bibliothèque Choisie*, tom. v. p. 145, tom. vi. p. 7. His other biographers are numerous; and we shall mention the most considerable lives which have appeared in a separate form. Knight's Life of Erasmus, more particularly that part of it which he spent in England. Cambridge, 1726, 8vo. Burigny, Vie d'Erasme. Paris, 1757, 2 tom. 12mo. Jortin's Life of Erasmus. London, 1758-60, 2 vols. 4to. Hess's Erasmus von Roterdam nach seinem Leben und Schriften. Zürich, 1790, 2 Bde. 8vo. Of M. de Burigny's work, a German translation, with corrections and additions, was published by Professor Henke. Halle und Helmstädt, 1782, 2 Bde. 8vo. Dr Knight's work had been translated into the same language by Theodor Arnold. Leipzig, 1735, 8vo.

34. E. Lat. 37. 30. N. This is also the name of a seaport in Asiatic Turkey, situated on the Black Sea. It is 100 miles east of Constantinople.

EREMIEU, a town of the department of the Isère, in France. It is surrounded with walls, and was the former residence of the dauphin or sovereign of Dauphiné. It contains 590 houses, and 2184 inhabitants, who are chiefly employed in making hempen cloth.

EREMONVILLE, a village in the department of the Oise, in France, containing 470 inhabitants. It is celebrated on account of a palace built by Henry IV. for his fair favourite Gabrielle, and afterwards the residence of Rousseau.

ERETRIA, a city on the western coast of the island Eubœa, founded along with Chalcis by a colony of Athenians, who were afterwards joined by a band of Æolians from Elis. Its extensive commerce raised it to considerable eminence at an early period; it founded colonies in the peninsula of Pallene, and also at Cumæ in Italy. It had under its dominion many of the neighbouring islands, as Andros, Ceos, and Teos, and was for many years the rival of the neighbouring city of Chalcis. Strabo (x. 448) states, as a proof of the wealth of the ancient inhabitants, that the festival of the Amarynthian Diana was often attended by 3000 soldiers on foot, with 600 cavalry and sixty chariots.

Eretria assisted the Ionians in their attempt to shake off the yoke of the Persian king, and was on that account exposed to the vengeance of Darius. It withstood for six days all the forces that could be brought against it; but it was at last betrayed into the hands of the enemy by the treachery of two of its principal citizens. The city was destroyed, and the inhabitants transported to Susa, whence Darius sent them to settle in the country of the Cissæi (Herodot. vi. 99, 119). Those inhabitants who had escaped rebuilt the city in a somewhat more northerly direction, as soon as the Persians had been compelled to retire. From this time it seems to have been subject to the Athenians, and to have continued in so peaceful a condition, that many of the learned, anxious to escape from the tumults of war, selected it as their residence. In later times it attached itself to the cause of Philip III. of Macedonia, and was on that account attacked by the Romans and plundered of all its statues and works of art (Liv. xxxii. 16). After the conquest of Greece by the Romans, it was declared free; but it never recovered from the blow it had received (Polyb. xviii. 28). Its ruins are to be found near a promontory which is situated opposite to the mouth of the river Asopus in Bœotia.

ERFURT, a city of the Prussian province of Saxony, and the capital of a circle of its own name, as well as of the provincial government. It is strongly fortified, and is defended by two forts, the Petersburg and the Cyrialsburg, both of most skilful construction. It is situated in a district of peculiar fertility, especially in garden fruits and seeds, the latter of which supply the seedsmen in distant parts of Germany. It sells large quantities of annis, canary, coriander, cummin, mustard, and poppy seeds; and much surplus corn. There was formerly a university, but it has declined, as well as most of the convents and monasteries which existed before its secularization. It now possesses a gymnasium and elementary schools, as well as many charitable establishments. It is a clean and well-built city, containing an ancient cathedral, with a lofty spire, and a bell weighing fourteen tons; eight Catholic and eight Lutheran churches, 2897 houses, and (in 1817) 18,218 inhabitants, now much increased in number. There have been lately erected some cotton spinning-mills; and other manufactures have since the peace very greatly extended. Being on the great road from Frankfort to Dresden and Leipsic, it has a considerable transit trade. Long. 11. 57. 17 E. Lat. 50. 59. 8. N.

ERGASTULUM, amongst the Romans, was a prison, work-house, or house of correction, where slaves were by the private authority of their masters confined and kept to hard labour for their offences. The Greeks had a place of confinement of the same sort.

ERIDANUS, a river celebrated in *Mythology* for the fall of Phaethon, and the metamorphosis of his sisters into long and slender poplars. Astronomers placed Eridanus in the heavens, and made it one of the southern constellations. It was supposed to be the ancient name of the river Po, but the difficulty of explaining the tradition of amber being gathered on its banks has excited doubts respecting the correctness of this information. Cluverius has suggested that the Eridanus of Herodotus may be the *Rhodaune*, a tributary of the Vistula; whilst others, knowing that amber was the staple product of the Baltic, are inclined to believe it the name of that sea, applied to it by mythologists, who were little acquainted with geography. (Virg. *Georg.* i. 412; *Æn.* vi. 659.)

ERIDANUS, in *Astronomy*, a constellation of the southern hemisphere, supposed to have the form of a river.

ERIE, a great lake of North America. It is about 280 miles in length from south-west to north-east, from ten to sixty-three in breadth, and about 658 in circumference. It has a depth of 120 feet; and its surface, which contains 12,000 square miles, is elevated 334 feet above that of Lake Ontario, with which it is connected by a canal, and 565 feet above the tide water at Albany, with which it is joined by the great Erie Canal. Through this immense sheet of water runs the boundary line which separates Canada from the United States. On its northern shore there are numerous projecting rocks, which render the navigation dangerous, particularly as there is no shelter from storms in that quarter. On the southern shore, however, there are several tolerably good harbours. The lake is navigated by a number of steam-boats, which of course are continually increasing in number, as civilization advances and commerce extends. The navigation upwards is rendered tedious, on account of a constant current which sets down the lake; and this is increased by the north-western and south-western winds, which here prevail. Long. 78. 35. to 83. 10. W. Lat. 41. 20. to 42. 50. N.

ERIGENA, JOANNES SCOTUS, a famous scholastic divine, was born about the beginning of the ninth century; but where, is a matter of dispute among authors. Bale and Pitts affirm that he was born at St David's in Wales; Dempster, Mackenzie, and Henry, that he was a native of Scotland. Dempster contends that he was born in Ayr, and in order to suit the name to the hypothesis, he describes him as Joannes Airigena. Du Pin, Sir James Ware, and Dr Ledwich have with greater probability asserted that he was by birth an Irishman, Ireland being in those days called *Scotia*, and by the natives *Erin*. Various writers agree in relating that he travelled to Athens, where he acquired a competent knowledge of the Greek and oriental languages; and that he afterwards resided many years in the court of Charles the Bald, king of France, who, on account of his singular abilities, treated him as his intimate friend and companion. He slept frequently in the royal apartment, and was constantly admitted to the king's table. "We may judge," says a modern historian, "of the freedom which he used with Charles, by the following repartee. As the king and Scotus were sitting one day at table, opposite to each other, after dinner, drinking a cheerful glass, the philosopher having said something that was not quite agreeable to the rules of French politeness, the king in a merry humour asked him, Pray, what is between a *Scot* and a *sot?* To which he answered, "Nothing but the table."[1] During his residence with Charles, he wrote several books of scholastic divinity, and was not so fortunate as to escape the imputation of heterodoxy. On that account the pope commanded Charles to send him to Rome, but the king had too great a regard for his companion to trust him with his holiness. One of the chief controversies in which Erigena was engaged, and with which the pope was much offended, was concerning the real presence. His opinion of this weighty matter is expressed in these few words: " What we receive corporally is not the body of our Lord, but that which feeds the soul, and is only perceived by faith."

Whether Erigena ended his days in France is a matter of doubt. Some of our historians tell us that he quitted it in the year 864; and that, after residing about three years in Oxford, he retired to the abbey of Malmesbury, where his scholars stabbed him with their pen-knives. There is no foundation for this story. Probably he died about the year 874; but whether in France or England, is uncertain, and of little importance. Some have related that he was invited to England by King Alfred; but they have apparently confounded him with John abbot of Etheling, who was assassinated in 895; and to this mistake the various accounts concerning Erigena are to be attributed. Besides many other works, he composed the following. 1. *Excerpta de Differentiis et Societatibus Græci Latinique Verbi.* 2. *De Divisione Naturæ lib. v.* 3. *De Prædestinatione Dei.* 4. *De Visione Dei.* 5. *De Corpore et Sanguine Domini.* 6. *Ambigua S. Maximi, seu Scholia ejus in difficiles locos S. Gregorii Nazianzeni, Latine versa.* 7. *Opera S. Dionysii quatuor in Latinam linguam conversa.* Most of these works have been printed. There is an edition, somewhat recent, of his books *De Divisione Naturæ.* Oxon. 1681, fol. The author was formerly denominated the Glory of the Greeks; an appellation to which, in the opinion of Montfaucon, he was not sufficiently entitled.[2] For the age in which he lived, he however appears to have been a person of eminent learning; and his translation of Dionysius Areopagita has received no mean commendation from Huet.[3]

ERIGONE, in fabulous history, daughter of Icarus. She died of grief on account of her father's death, was translated into heaven, and formed the sign Virgo.

ERITH, a town of the county of Kent, in the hundred of Lessness and lathe of Sutton, fourteen miles from London. It stands on the right bank of the Thames. It is chiefly inhabited by fishermen and other seafaring people; but Belvedere House, on the site of an ancient monastery, is one of the most striking objects to passengers in vessels ascending or descending the Thames. The population amounted in 1801 to 969, in 1811 to 1119, in 1821 to 1363, and in 1831 to 1533.

ERIVAN, a province of Persia, bounded on the north and west by the Mossian Hills, on the south by the Araxes, and on the east by the districts of the Karabang and Karadang. It is of considerable extent, and has a salubrious climate, though the winter is of long duration. It possesses, according to Sir R. K. Porter, by whom it was visited in 1817, every natural beauty which a fine assemblage of mountain, dale, and water can bestow. The principal towns are Erivan and Nackshivan. This province is ruled by a sardar, who differs from most others in the empire, as he pays no tribute to the king, holding his station by a military tenure, by which he is bound to furnish to the royal army in time of war a certain quota of troops. To him is entrusted the defence of the frontier within the limits of the province; so that he more resembles a prince in his authority, as well as in all his appointments, than a provincial governor. He has immense wealth both in money and in land. The province is 200 miles in length and 100 in breadth. According to a general census taken in 1814, the number of inhabitants capable of bearing arms amounted to 18,000. The annual revenue is 150,000 tomauns, or L.75,000 sterling.

ERIVAN, *Irwan*, or *Irivan*, the capital of the above province, situated in an angle of a great plain at the foot of the Mossian Hills, on the banks of the river Zengui, which rises from a lake about seventy miles farther north, and falls into the Araxes about three leagues below the town. It is defended by a fortress of an elliptical form, upwards of 6000 yards in circumference. The city is of considerable extent, but, as generally happens in Persia, ruins mingle everywhere with the habitable parts of the town. The north-west side of the town is built on a precipice impending over the river, to the height of 600 feet. The fortress spreads over a great deal of ground. It is fortified in the mixed ancient and modern Asiatic manner; and has been lately strengthened by European engineers. But it is commanded on every side by hills at a distance of scarcely 6000 yards. The Zengui flows close past the north-west front, which is on the summit of a perpendicular rock seventy feet deep, forming a natural ditch. " Nothing," says Sir R. K. Porter, " can exceed the grandeur of these bulwarks of nature, which so frequently present themselves around fortified places in those precipitous countries; their vastness, simplicity, and impregnable appearance being far beyond the powers of man to imitate." The walls of Erivan, with their numerous towers, make a line of defence exceeding 2000 yards. Immediately beyond them a fine stone bridge crosses the river, which is almost the only object in the town that does not appear in a state of ruin or decay. Erivan has been so often the scene of devastation, plunder, and massacre, that the population has dwindled to about 15,000 persons. The singular old tower described by Chardin being struck with lightning and greatly damaged, has been pulled down, and the materials appropriated to the repairs of the town. The city is well supplied with water from the little river Querk-boolak, which has its source in the great lake, and runs thence north-east, but on approaching the city is divided into numberless little canals for the irrigation of the surrounding gardens, or for other purposes. Sir R. K. Porter supposes that the Erivan was founded sixty-five years before the Christian era, by Ervandus, one of the Armenian kings. In 1635 it was taken from the Turks by the Persians, and its position changed to its present site. It was besieged in 1724 by the pasha of Diarbekir, who in four successive attempts to storm it lost about 24,000 men. It afterwards capitulated, after a brave defence. It was taken by Nadir Shah in 1748, and has since remained in possession of the Persians. In 1808 it was blockaded for six months by the Russians, who, in attempting to storm, were repulsed with great slaughter, and lost half their army in its retreat to Tiflis. It was taken by them in 1829, and given up to Persia by the subsequent treaty of peace. Long. 44. 35. E. Lat. 40. 9. 30. N.

ERIPHYLE, in fabulous history, a sister of Adrastus king of Argus, who married Amphiaraus. She was daughter of Talaus and Lysimache. When her husband concealed himself in order that he might not accompany the Argives in their expedition against Thebes, where it had been predicted he was to perish, Eriphyle suffered herself to be bribed by Polynices with a golden necklace which had been formerly given to Hermione by the goddess Venus, and discovered where Amphiaraus lay hidden. This treachery of Eriphyle compelled him to go to the war; but before he departed, he charged his son Alcmæon to murder the betrayer as soon as he received information of his death. Amphiaraus perished in the expedition; and his death was no sooner known than his last injunctions were obeyed, and Eriphyle was murdered by the hands of her son.

[3] Huetius de Interpretatione, p. 154.

ERIS, the goddess of discord among the Greeks. She is the same as the *Discordia* of the Latins.

ERISICHTHON, in fabulous history, a Thessalian, son of Triops, who derided Ceres and cut down her groves. This impiety irritated the goddess, who afflicted him with continual hunger; in consequence of which he squandered all his possessions in order to gratify the cravings of his appetite, and at last devoured his own limbs for want of food. Some say that his daughter had the power of transforming herself into whatever animal she pleased, and that she made use of this artifice in order to maintain her father, who had sold her, after which she assumed another shape, and again became his property.

ERLANGEN, a city of the circle of the Rezat, in the kingdom of Bavaria. It stands on the river Wernitz, is surrounded with ancient walls and towers, and though antique, is well built, and has broad streets. It contains a royal palace, three Lutheran churches, two Reformed, and one Catholic, and 815 houses, with 9800 inhabitants. It is the seat of the only exclusively Protestant university in the kingdom, which has twenty-six professors, and about 200 students, with a library of 80,000 volumes, a botanic garden, and several museums, with an anatomical theatre, and a chemical laboratory. There are numerous manufactures carried on, of cottons, hats, hosiery, gloves, paper, cutlery, &c. Long. 9. 1. 5. E. Lat. 49. 35. 36. N.

ERLAU, or EGER, a city of Hungary, in the circle of the Hither Theiss. It contains an Episcopal palace and cathedral, a university with ten professors, an observatory and public library, three cloisters for monks and one for the Brethren of Mercy, with 1710 houses, and 16,112 inhabitants. There are here manufactures of linen and woollen goods, and much good wine is also made. Long. 20. 17. 51. E. Lat. 47. 53. 36. N.

ERMIN, in *Heraldry*, denotes a white field or fur, powdered or interspersed with black spots, called *powdering*.

ERMIN, an order of knights instituted in 1450, by Francis I. duke of Bretagne, and which formerly subsisted in France. The collar of this order was of gold, composed of ears of corn in saltier, at the end of which hung the ermine, with the inscription *à ma vie*. But the order expired when the dukedom of Bretagne was annexed to the crown of France.

ERMINES, in *Heraldry*, the reverse of ermine, that is, white spots on a black field.

ERMINOIS, in *Heraldry*, signifies the field or, and the spots black.

ERNATIA, a town of Asiatic Turkey, in Natolia, situated on the Gulf of Satalia, sixteen miles north-west of Satalia. Long. 30. 24. E. Lat. 36. 50. N.

ERNESTI, JOHN AUGUSTUS, one of the most illustrious philologers and theologians of the last century. He was born on the 4th August 1707, at Tennstadt, of which place his father, likewise a distinguished theologian, was pastor, and superintendent of the electoral dioceses of Thuringia, Salz, and Sangerhusen. After having received his first instruction in the learned languages, under the domestic discipline of his father, and in the gymnasium of his native town, he was sent at the age of sixteen to the celebrated Saxon cloister school of Pforta. Here he continued four years. At the age of twenty he entered the university of Wittemberg, where he studied eloquence and ancient literature under the celebrated Berger, theology under Wernsdorf, and the Wolfian philosophy under Schlosser. From Wittemberg he passed to the university of Leipsig, where he applied himself to the mathematical sciences under Hausen, following the courses of Boerner and Deyling on theology, and the lectures of Gottsched on German eloquence. In 1730 he was made master in the faculty of philosophy. In the following year he accepted the office of conrector in the Thoman school of Leipsig, of which J. M. Gesner was then rector; and on Gesner's vocation, as professor of eloquence, to Göttingen, he succeeded him as rector. In this situation, by his erudition, diligence, and the elegance of his methods, he surpassed all his contemporaries, and created an epoch in Germany for the study of the ancient authors. From this office, in opposition to the present custom, which precludes a translation into the universities to the masters of the subordinate schools, he was, in 1742, named as extraordinary professor of ancient literature in the university of Leipsig, and in 1756 promoted to the ordinary professorship of eloquence. In both these chairs he knew how to combine more intellect, philosophy, and taste, than had been done by any of his predecessors. His reputation as a scholar, and his rational treatment of the biblical exegesis, paved the way for his entrance into the theological faculty. Through the elegance of his learning, and his manner of discussion, he co-operated with Baumgarten of Halle in disengaging dogmatic theology from the scholastic and mystical excrescences with which it was then deformed; and thereby contributed greatly to the new revolution in theology, although he himself never deviated from the ancient system. In these deserving labours, and with unbroken health, he attained an honourable old age; and died, after a short illness, in his seventy-sixth year, on 11th September 1781.

Whether Ernesti be considered as a philologer or theologian, it is perhaps as much from the impulsion which he gave to sacred and profane criticism in Germany, as from the intrinsic excellence of his own works in either department, that he must derive his reputation. With Gesner, he instituted a new school in ancient literature; and, after Crocus, Melanchthon, and Camerarius, has been perhaps the greatest reformer and promoter of classical learning in Germany. With Semler he partially co-operated in the great revolution of Lutheran theology; though he is guiltless of all participation in the deductions which many of those who profess themselves his disciples have drawn from the principles which he established.

An enthusiastic and enlightened study of the ancient Greek and Roman authors is the well-merited boast of the present German literature. This commenced, in its existing form, towards the middle of the last century. Not that Germany, before that period, had neglected ancient literature, or could not enumerate her proportion among the great names of classical erudition. No nation, in fact, had produced so many, or more illustrious, scholars immediately after the Reformation; but for a long time polite literature had become deformed, if not neglected, in proportion as religious wars and polemical theology had exhausted and engrossed her governments and universities. The German scholars were chiefly theologians, and theologians who had studied every thing in reference to their peculiar profession. Add to this, that the most disgusting and inefficient methods had been introduced, whereby the spirit of the instruction was at utter variance with the object of the study. Accordingly, during the whole of the seventeenth and the first half of the eighteenth century, Germany was far excelled by Holland in the number and excellence of her philologers; and it was not until the appearance of Gesner and Ernesti, with their somewhat earlier contemporaries, Cortius, Daniel Longolius, and Michael Heusinger, that she could oppose above one or two rivals to the great critics of the Dutch schools. Gesner and Ernesti, however, through the influence of their lectures at the greater universities of Göttingen and Leipsig, through the wider extent of their labours in philology, and still more through the greater excellence of their methods, are alone entitled to be held the founders of the new German school of ancient literature. Both excelled their philological countrymen in taste, in the elegance of their Latin style, in a philosophical spirit, and in a wider acquaintance with the subsidiary branches of erudition. Both made an advantageous use of their critical knowledge of the languages; both looked at once to the words and to the subject of the ancient writers, established and applied the rules of a legitimate interpretation, and carefully analysed the meaning as well as the form of the expression. Both contributed effectually to expel the old absurd and disgusting methods of instruction from the schools and universities, and to introduce an improved and more effectual system. To the epoch which they formed, many circumstances indeed contributed:—their acquaintance with the Dutch criticism; the universal enthusiasm of the Germans for establishing a national literature, and for becoming at the same time reformers in the departments of ancient learning; and withal the spirit of philosophy which at that period in Germany began more and more to blend itself with every part of science and literature. It is also true that their editions do not possess the complement of erudition and criticism which distinguish those of many of their contemporaries; their commentaries have the precision, but how inferior are they in certainty, copiousness, and depth of illustration, to those of the philologers of Holland? In their editions of the Latin classics, they returned back to the somewhat inconvenient method of Cellarius, collecting their principal illustrations into an *Index Rerum et Verborum*, as is done by Gesner in his *Quintilian*, and by Ernesti in his *Cicero*; not, however, that they did not possess the means of illustrating their author with a rich critical and philological commentary, of which the former has given ample proof in his editions of the *Scriptores de Re Rustica*, and in his *Claudian*, and the latter in his two most valuable labours, his *Suetonius* and *Tacitus*. Both, but especially Ernesti, have detected grammatical niceties in the Latin tongue, which had escaped all preceding critics; such, among others, are the use of the subjunctive mood after the pronoun *qui*, and the legitimate consecution of the tenses. His canons are, however, not without exceptions. As an editor of the Greek classics, Ernesti deserves hardly to be named beside his Dutch contemporaries, Hemsterhuis, Valkenaer, Ruhnken, or his colleague and enemy the learned and unfortunate Reiske. How insignificant are his own labours in his editions of Homer and Callimachus? In regard to the higher criticism, it was not even attempted by Ernesti. But to him and to Gesner the peculiar praise is owing of having formed, partly by their discipline, and partly by their example, philologers greater than themselves; and to them is due the honour of having so strongly excited in Germany that enthusiasm for ancient learning, which has now, unfortunately, no parallel in the other countries of Europe.

As a theologian, Ernesti is far less conspicuous than as a scholar, and his influence not so marked either on his contemporaries or on his successors. Before the middle of the eighteenth century, the Spenerian pietism had been almost banished from the Lutheran theology; and the professors of that faculty in the Protestant universities of Germany no longer excluded philosophy from all interference in the doctrine of Christian belief. It had then been boldly proclaimed and maintained with pre-eminent ability by Semler, that Luther had commenced and not finished the Reformation of religion; but that this Reformation must still proceed, and that religion, like other branches of knowledge. must become purer and more perfect in proportion to the increase of knowledge and the development of the human mind. At this date, accordingly, the theologians of Germany had begun to disregard the nonconformity of their doctrines with the formula of the Lutheran church; and after this period few were at all apprehensive of openly controverting its tenets when at variance with the results of their own speculations. From the unrestrained freedom of thought in matters of religion which was now indulged, if not even encouraged, by the governments in their different universities, every one was at perfect liberty, without any derogation from his character as a clergyman or instructor, to maintain and promulgate what opinions in religion he chose; and it must be acknowledged that the theologians have made, and are still making, every use and abuse of this license, and have arrived at every conclusion that piety and learning, as well as presumption, folly, and irreligion can suggest. It was at the commencement of this important era that Ernesti flourished as a theologian.

Of the three sciences subsidiary to theology, philosophy, history, and grammatical exegesis, the first had been imperfectly applied, and without any interesting result, by Baumgarten, a scholar of Wolf; but the second, the historical interpretation, had, in the hands of Semler, been productive of conclusions subversive of much that had been hitherto held orthodox and even sacred. In the grammatical interpretation of the New Testament some imperfect progress had been made by Bengel; but the new epoch in the biblical exegesis commences with John David Michaelis for the Old, and with Ernesti for the New Testament. It is, indeed, chiefly in *hermeneutic* that Ernesti has any claim to the character of a great theologian. But here his merits are distinguished, and, at the period when his *Institutio Interpretis N. T.* was published, almost peculiar to himself. He applied himself to the interpretation of the sacred Scriptures, after a long and familiar acquaintance with the Greek and Roman writers, and when formed in his mind and taste by a constant study of these patterns. His interpretation of the New Testament bears the character of both these circumstances. It is not only the matter, but at the same time the manner in which it is conveyed,—it is the selection of subjects, with the precision, the pregnant brevity, the elegance and simplicity, in which they are expressed,—that confers on this little book so high and so singular a value. We find in it the principles of a general interpretation, and this without the assistance of any particular philosophy, not even of the Wolfian, to which Ernesti was attached; but consisting of observations and rules, which, though already enunciated, and applied in the criticism of the profane writers, had never rigorously been employed in the biblical exegesis. He admits in the sacred writings only *one acceptation*, and that the *grammatical*, convertible into and the same with the *logical* and *historical*. The Scriptures, therefore, having this in common with all other writings, it follows that they can only be explained like mere human compositions; that the rules of interpretation are the same in both; and that only through some peculiar constitution of speech and writing could any possible distinction between these subsist. He therefore justly censures the opinion of those who, in the illustration of the Scriptures, refer every thing to the illumination of the Holy Spirit; as well as that of others who, in contempt of all knowledge of the languages, would explain words by things, and thus introduce into the holy writings their peculiar glosses and opinions. The *analogy of faith*, as a rule of interpretation, he greatly limits, and teaches that it can never alone afford the explanation of words, but only determine the choice among their possible significations, and must always stand in need of philology as an assistant. The spirit of Ernesti's interpretation gives no countenance, however, to the results which many of his followers have deduced from the grammatical and historical exegeses. Every principle of his interpretation rests on the assumed inspiration of the holy books; and there is not perhaps a better antidote to the poisonous tenets of many of those who profess to be of his school, than the diligent study of his *Interpres*, and the relative *Acroases* of Morus. In the higher criticism of the sacred books Ernesti did nothing. In dogmatic he always expressed great contempt of strict systematic theology; and though he lectured for many years on the Aphorisms of Neumann, it was rather in refutation than in support of his text-book.

Among his works the following are the more important:

I. In profane literature:

Initia Doctrinæ Solidioris, 1736, 8vo; many subsequent editions. A work not only valuable by reason of the real excellence of the matter, but more particularly deserving an attentive study, on account of the purity of the Latin, in discussing subjects of philosophy known only to the moderns.

Initia Rhetorica, 1730.

Xenophontis Memorabilia Socratis, cum notis, 1737; often reprinted.

Ciceronis Opera cum clave, 1737; 2d edit. Halæ, 1757; 3d edit. ibid. 1776, 8vo, 6 vols.

Suetonius cum Animadversionibus, 1748; 2d edit. 1775-8.

Taciti Opera cum notis J. Lipsii, Jo. Fr. Gronovii et suis, 1752; 2d edit. 1772; 8vo. Another edition, with many additions and improvements, has been procured by Oberlin.

Aristophanis Nubes cum Scholiis Antiquis et præfatione, 1754, 8vo.

Corradi Quæstura cum præfatione, 1754, 8vo. See Wyttenbach in his *Vita Ruhnkenii.*

Hederici Lexicon Græcum, multis Vocabulorum millibus Auctum, 1754–67, 8vo.

Homeri Opera Omnia, ex Recensione, et cum Notis Sam. Clarkii, accessit Varietas Lectionum MS. Lips. et Edit. Vet. cura J. A. E. qui et suas Notas adspersit, 1759–64, 5 vols. 8vo.

Callimachi Hymni et Epigrammata, cum Notis Var. Latine vertit atque Notis adjecit. Lugd. Bat. 1761, 8vo, 2 vols.

Polybius cum Notis Var. Præfationem et Glossarium Polybianum adjecit. Viennæ et Lips. 1764, 3 vols. 8vo.

Archæologia Litteraria, 1768. A new and improved edition by Martini.

Horatius Tursellinus de Particulis, 1769, 8vo.

Fabricii Bibliotheca Latina nunc melius delecta, rectius digesta et aucta, vol. i. and ii. 1773; vol. iii. 1774, 8vo, unfinished.

II. In sacred literature:

Antimuratorius sive Confutatio Disputationis Muratorianæ de rebus Liturgicis, 1755–58.

Neue Theologische Bibliothek, vol. i. to x. 1760–69, 8vo.

Institutio Interpretis Nov. Test. 1761, reprinted in the same year at Leyden; 2d edit. 1765; 3d edit. 1775; 8vo.

Neueste Theologische Bibliothek, vol. i. to x. 1771–75, 8vo.

Besides these, he published above a hundred smaller works in the form of prefaces, academical dissertations, programmata, memoriæ, elogia, epistles, orations, translations, &c. Many of these have been collected in the three following publications:—*Opuscula Oratoria*, Lugd. Bat. 1762; 2d edit. 1767; 8vo. *Opuscula Philologica et Critica*, Lugd. Bat. 1764; 2d edit. 1776; 8vo. *Opuscula Theologica*, Lips. 1773, 8vo.

EROS (from ερως, *love*), in *Mythology*, one of two chiefs of the cupids, being the cause of love.

EROSION, among physicians, denotes nearly the same thing with corrosion, only in a stronger degree.

EROTIA, a festival instituted in honour of Eros, the god of love. It was celebrated by the Thespians every fifth year, with sports and games, when musicians and others contended. If any quarrels or seditions had arisen amongst the people, it was then usual to offer sacrifices and prayers to the god that he would totally remove them.

EROTIC (derived from ερως, *love*, whence ερωτικος) is applied to any thing which has a relation to the passion of love.

EROUAD, or Erroad, a town of Hindustan, in the province of Coimbetoor. It contained during the reign of Hyder about 3000 houses, but was reduced to one third in the reign of Tippoo; and during the invasion of General Meadows the town was destroyed. It is now fast recovering, and contains about 400 houses. It was taken by the British in 1768, and retaken the same year by Hyder. It was again taken by the British in 1790, and retaken by Tippoo; but it came into the final possession of the British, along with the province, in 1799. A canal has lately been cut in its vicinity, and is expected to be productive of much benefit to the inhabitants. Long. 77. 50. E. Lat. 11. 19. N.

ERPENIUS or d'Erpe, Thomas, a celebrated orientalist, born at Gorcum in Holland, on the 7th September 1584. Observing his aptitude for learning, his father sent him to Leyden at the early age of ten; and it was in that city that he commenced his studies. At the end of several months, however, he went to Middelburg, where he remained some time; but in about a year he returned to Leyden, where he had opportunities of indulging his tastes with greater facility. His progress was so rapid, that at a very tender age he was admitted into the university of that city, and in 1608 took the degree of master of arts. At the solicitation of Scaliger he learned the oriental languages whilst taking his course of theology, and even then gave promise of the distinction which he was destined to attain in that department of learning. After he had completed his studies he travelled in England, France, Italy, and Germany, forming connections with learned men, and availing himself of the information which they communicated. During his stay at Paris, he contracted a friendship with Casaubon, which lasted during his life, and also took lessons in Arabic from Joseph Barbatus, otherwise called Abu-dakni. At Venice he held conferences with both Jews and Mahommedans, and profited by his residence in that city to perfect himself in the Turkish, Persic, and Ethiopic languages. After a long absence, Erpenius returned into his own country in 1612, rich in the learning which he had acquired during his travels, as well as beloved and esteemed by all the learned whom he had visited. His acquirements being already known and appreciated, he was, on the 10th February 1613, appointed professor of Arabic and other oriental languages, Hebrew excepted, in the university of Leyden. From this period he devoted himself solely to the teaching of these languages, to facilitate the study of them, and to extend a knowledge of them by means of his works. Animated by the example of Savary de Brèves, who had established at his own charge an Arabic press at Paris, he caused new Arabic characters to be cut at a great expense, and erected a press in his own house. In 1619 the curators of the university of Leyden instituted a second chair of Hebrew in his favour. In 1620, the States of Holland sent him to France, to endeavour, by the promise of a chair of theology, to induce Pierre Dumoulin or André Rivet to settle in that country; but this first journey proved unsuccessful, and was followed, the year after, by a second, which

Erpenius.

had the desired effect, as Rivet closed with the terms offered him, and passed into Holland. Some time after the return of Erpenius, the States appointed him their interpreter; an office which imposed upon him the duty of translating and replying to the different letters of the Moslemin princes of Asia and Africa. The king or emperor of Morocco, it is said, took great pleasure in reading his Arabic letters, and in pointing out the elegance and purity with which they were written. But be this as it may, the reputation of Erpenius had now spread throughout all Europe; and several princes, the kings of England and Spain, and the archbishop of Seville, made him the most flattering offers; but he constantly refused to leave his native country, and died of a contagious distemper on the 13th of November 1624, at the early age of forty. Erpenius left several works, which are doubtless not perfect; but if we consider that he lived in an age when pursuits like his were exceedingly rare, if not wholly new, that he had little or no assistance of any kind, and that in fact he formed himself; and if we judge him, not according to the present state of oriental literature, but by what he actually achieved under every disadvantage, we must conclude that, in the immensity and difficulty of his labours, he probably surpassed all the orientalists who have followed him; and that if his career had not been cut short by a premature death, he would have greatly enlarged the boundaries of that literature of which his name will always remain one of the greatest ornaments. The following is a list of his works:—1. *Oratio de Lingua Arabica*, Leyden, 1613, in 4to; 2. *Annotationes in Lexic. Arab. Fr. Raphelengii*, ibid. 1613, in 4to; 3. *Grammatica Arabica, quinque libris methodice explicata*,[1] ibid. 1613, in 4to; 4. *Proverbiorum Arabicorum centuriæ duæ, ab anonymo quodam Arabe collectæ*, ibid. 1614 and 1623, in 8vo; 5. *Locmani sapientis Fabulæ et selecta quædam Arabum Adagia, cum interpretatione Latina et notis*, ibid. 1615, in 8vo; 6. *Pauli Apost. ad Romanos, Arabice*, ibid. 1615, in 4to; 7. *Novum D. N. J. C. Testamentum, Arabice*, ibid. 1616, in 4to; 8. *Pentateuchus Mosis, Arabice*, ibid. 1622; 9. *Historia Josephi Patriarchæ ex Alcorano, cum triplici versione Latina et scholiis Th. Erpenii, cujus præmittitur Alphabetum Arabicum*, ibid. 1617, in 4to; 10. *Grammatica Arabica dicta Giarumia et libellus centum regentium cum versione Latina et Commentariis*, ibid. 1617, in 4to; 11. *Canones de litterarum Alif, Waw, et Yé apud Arabes naturo et permutatione*, ibid. 1618, in 4to; 12. *Rudimenta Linguæ Arabicæ; accedunt Praxis Grammatica et consilium de studio Arabico feliciter instituendo*, ibid. 1620, in 8vo; 13. *Orationes tres de linguarum Ebreæ et Arabicæ dignitate*, ibid. 1621, in 12mo; 14. *Historia Saracenica*, ibid. 1625, in fol.; 15. *Grammatica Ebræa Generalis*, ibid. 1621, in 8vo; 16. *Grammatica Syra et Chaldæa*, ibid. 1628; 17. *Psalmi Davidis, Lyriace*, ibid. 1628; 18. *Arcanum punctuationis revelatum et Oratio de nomine Tetragrammato; 19. Versio et Notæ ad Arabicam Paraphrasin in Evang. S. Joannis*, Rostock, 1626; 20. *De Perigrinatione Gallicâ utiliter instituenda tractatus*, ibid. 1631, in 12mo; 21. *Præcepta de Lingua Græcorum communi*, Leyden, 1662. Erpenius had projected several other works, particularly an edition of the Koran with notes, and an oriental library; and in the prefaces of his grammars he also speaks of a *Thesaurus Grammaticus*, which, however, has not seen the light. For further information respecting this celebrated orientalist, the learned reader may consult Vossius, *Oratio in obit. Th. Erpenii*, Leyden, 1625, in 4to, and Scriverius, *Manes Erpeniani, quibus accedunt Epicedia variorum*, ibid. 1625.

ERPETOLOGY. See Reptilia.

ERRATIC, in general, something that wanders, or is not regular. Hence the planets are called *erratic stars.*

ERROMANGO, an island in the South Pacific Ocean, one of the New Hebrides, about ninety miles in circumference. The inhabitants are black. Long. 169. 20. E. Lat. 13. 50. S.

ERROOR, a fortified town of the south of India, in the province of Mysore. The Hoggree river runs close past the fortifications, to which there is a flight of steps from the water's edge, built by some pious Mahommedan. It was plundered by the Mahrattas in 1790. Long. 76. 39. E. Lat. 13. 48. N.

ERROR, in *Philosophy*, a mistake of the judgment, or giving assent to that which is not true. Mr Locke reduces the causes of error into these four: first, want of proofs; secondly, want of ability to use them; thirdly, want of will to use them; and, fourthly, wrong measures of probability.

ERSKINE, Thomas, Lord Erskine, a distinguished lawyer and statesman, was the third and youngest son of David Henry Erskine, tenth earl of Buchan, in Scotland. He was born in Scotland, and received his education partly at the high school of Edinburgh, and partly at the university of St Andrews. From the contracted resources of his family, it was necessary for him to fix upon a profession. He chose the navy, and having embarked at Leith as a midshipman, he quitted his native country, which he did not revisit until a few years before his death. In the navy he experienced no advancement, and, after four years' service, he entered the army in the year 1768. In 1770 he married, and shortly after this event he accompanied his regiment to Minorca, where he remained during three years. It is not certain whether his abilities as an officer ever rendered him conspicuous, but the versatility of his talents, and the acuteness of his intellect, thus early brought him a high reputation. By the earnest persuasion of his mother, who, it would appear, was a woman of more than ordinary penetration, he was induced to quit the army after six years of military probation. The legal profession was the one which appeared best adapted for the character of his mind; and in 1777 he entered as a fellow commoner at Trinity College, Cambridge, for the purpose of obtaining a degree, which he was entitled to as the son of a nobleman, and thereby of shortening his passage to the bar. At the same time he entered himself as a student at Lincoln's Inn. In 1778 he was called to the bar, where his success was immediate and remarkable. In a case of libel, in which he advocated the cause of Captain Baillie, the defendant, he displayed so much eloquence and talent, that the legal world was astonished, and thirty retainers were put into his hand by attornies before he left the court. A few months after this event he was honoured by being chosen to appear at the bar of the House of Commons, as counsel against a bill of Lord North's to restore to the universities the monopoly in almanacks. The bill was lost by a large majority, and the speech which Mr Erskine made upon the occasion so established his reputation for forensic skill, that he was from this period engaged, either on one side or another, in every case of importance, during a practice of twenty-five years. To this period also belongs his famous speech in defence of Lord George Gordon, which was a case of what is called constructive treason. Erskine procured a clear acquittal of his client, which was for the time a deathblow to the tremendous doctrine of constructive treason. In May 1783 he received a silk gown, and the same year was elected member of parliament for Portsmouth, for which borough he was on every election re-chosen, until his advancement to the peerage rendered that honour unnecessary. When the eldest son of George III. obtained his establishment as Prince of Wales, he chose Mr Erskine as his attorney-general. But there is nothing in the life of this eminent man which reflects so much honour on his memory as his exertions in defence of the privileges of juries. The rights of those *pro tempore* judges he strenuously maintained upon all occasions, particularly in the celebrated trial of the Dean of St Asaph, for libel, when Justice Buller refused to receive the verdict of *guilty of publishing only*, as returned by the jury. In 1789 another opportunity was afforded him to display his peculiar powers. This was the defence of a Mr Stockdale, a bookseller, who was tried on an information filed by the attorney-general, for publishing what was charged as a libellous pamphlet in favour of Mr Hastings. The situation of the latter, whose celebrated but protracted trial was then dragging its slow length along, gave Erskine admirable scope for that animated appeal to the feelings, by which his speeches are so much distinguished. It is one of his finest orations; and, whether we regard the wonderful skill with which the argument is conducted, the soundness of the principles laid down, and their happy application to the case, the vividness of fancy with which these are illustrated, and the touching language in which they are conveyed, it is justly to be regarded as a consummate specimen of the art of addressing a jury. This masterly defence procured a clear acquittal for Stockdale, although the fact of publication was admitted. Not long afterwards he advocated the cause of Mr Perry, editor of a London newspaper, who was also charged with publishing what the jealous loyalty of those times construed into a libel; and his speech produced a similar result. But the most arduous effort of his professional life arose out of the part cast upon him, in conjunction with Mr, afterwards Sir Vicary, Gibbs, in the trials of Hardy, Tooke, and others, for high treason in 1794. These trials lasted several weeks, and the ability displayed by Mr Erskine upon this memorable occasion was acknowledged and admired by men of all parties. His speech in defence of Mr Frost, which, however, preceded those above mentioned, is another of those almost miraculous exertions, which, in that momentous crisis, Mr Erskine made for the liberties of his country. Frost was accused of uttering seditious words, which, however, turned out to have been spoken at random in a coffee-house whilst the accused was in a state bordering on intoxication. In the violence of that day, the exertions of Erskine failed of their accustomed effect, and Frost was found guilty. But the impression of his defence was not lost; and it deterred the government from risking its credit on such precarious speculations, until, as we have noticed, the charges of high treason were brought forward, when the whole force of the bar was marshalled against the prisoners, and every effort used to beat down and paralyse their undaunted defender. But his spirit rose superior to every difficulty, and then it was that his consummate talents shone forth in their native lustre. His indefatigable patience, his sleepless watchfulness, his unceasing activity of body and mind, his untameable spirit, his quickness and subtilty of intellect, together with a herculean strength of constitution, counterbalanced the host to which he was opposed. Such were the gigantic powers of the man; the wonderful eloquence of the forensic orator is only to be spoken of as second to these.

---

[1] This grammar, says Schnurrer, which may be regarded as the first composed in Europe, has not only been often reprinted, but it has so made the law, or, in other words, served as a model, that several professors, particularly in Germany, who have published Arabic grammars under their own names, have followed the footsteps of Erpenius, and have never ventured to deviate from the course marked out by their guide.

Mr Erskine was a warm partizan of Mr Fox, and the liberal party of that time. He strenuously opposed the war with France, and published a pamphlet against it, entitled *A View of the Causes and Consequences of the War with France*, which had an immense sale. In 1802 the Prince of Wales not only restored him to his office of attorney-general, of which he had been deprived, but made him keeper of the seals for the duchy of Cornwall. On the death of Pitt in 1806, when Lord Grenville received orders to form a new administration, Mr Erskine was created a peer, by the title of Lord Erskine, of Restormel Castle in Cornwall, and elevated to the dignity of lord high chancellor of Great Britain. His previous experience in the courts of common law scarcely fitted him for the judicial functions of this dignified office; but there seems little doubt that his natural quickness of intellect would have triumphed over every difficulty, had not a dissolution of the administration of which he formed part been accelerated by the obstinacy of the king on the subject of the Catholic claims. His public career may be said to have terminated with this event, and the remainder of his life was undistinguished by any great exertion, whilst it was unhappily embittered by pecuniary difficulties, which were enhanced, it is said, by an unfortunate second marriage. His mind, however, retained its native elasticity, and in his retirement he employed himself in editing several of the state trials. He also wrote the preface to Fox's speeches, a political romance entitled *Armata*, and several pamphlets in support of the Greek cause. Whilst accompanying one of his sons by sea to Edinburgh, he was seized with an inflammation of the chest, which compelled him to land at Scarborough. He reached Scotland by easy stages, but expired on the 17th of November 1823, at the seat of his brother, situated a few miles from Edinburgh. The peculiar character of Lord Erskine's eloquence has already in some measure been described. In his capacity of advocate he possessed the power of summoning upon the instant all the resources of his mind, and bringing them to bear upon the subject before the court with extraordinary effect. In this respect his speeches bear a resemblance to those of Mr Pitt, whilst they far surpass them in impassioned fervour, in brilliancy of imagination, in copiousness of imagery, and in that quality of mind expressed by the emphatic word genius. His dexterity was likewise unrivalled at the bar; and these qualifications, united with a courage which nothing could daunt, and a firmness which was never overcome, rendered him almost irresistible on the defensive side of political persecution. Amidst all the struggles of the constitution in parliament, in council, and in the field, during that momentous period of our national history, there was no man to whose individual exertions it owed so much as to those of this celebrated advocate. In stemming the tide of state prosecutions, this single patriot may be said to have saved his country from the horrors of a general proscription. As a senatorial orator his claims were but secondary; and as a political writer he is not entitled to much distinction. His sphere was the bar, and there, as the advocate of injured worth or persecuted political honesty, he never had a rival before, and he has left no equal behind him.

By his first wife, who died in 1805, Lord Erskine had three sons and five daughters. His speeches have been frequently printed; the last edition is in 5 vols. 8vo. (R. R. R.)

ERYMANTHUS, a mountain, river, and town of Arcadia, where Hercules killed a prodigious boar, the carcass of which he carried on his shoulders to Eurystheus, who was so terrified at the sight that he hid himself in a brazen vessel.

ERYSIPELAS, in *Medicine*, an eruption of a red or fiery kind, from which no part of the body is exempted, though it chiefly attacks the face.

Erythræ || Erzerum.

ERYTHRÆ, in *Ancient Geography*, a port of Ætolia, on the Bay of Corinth. The Erythræans considered the Sibyl Herophile as their countrywoman, and she was thence surnamed *Erythræa*. Erythræ was famous for an ancient temple of Hercules.

ERYTHRÆUM MARE was used, at the time when the Greeks possessed little accurate information respecting India, to designate the whole ocean to the south of Asia, which washed the coasts of Arabia, Persia, and Western India. The boundary of the Erythræan Sea was determined by a line drawn from the outlet of the Red Sea or Arabian Gulf, to the southern extremity of India. Its name was probably derived from that of some prince; for we can scarcely ascribe it to any supposed redness of colour, which the word in the Greek language means. In course of time, however, it was restricted to the sea south of Arabia; and in this signification it was understood by Strabo (xvi. 765, 766). Herodotus (i. 180), indeed, seems to have known nothing of the Persian Gulf, but to have considered the river Euphrates as falling at once into the *Mare Erythræum*.

ERYX, a son of Butes and Venus, who, relying upon his strength, challenged all strangers to fight him with the cestus. After many had yielded to his superior dexterity, Hercules accepted his challenge, and Eryx was killed in the combat, and buried on the mountain, where he had built a temple to Venus (Virg. *Æn.* v. 402). A mountain of Sicily near Drepanum also received its name from Eryx, who was buried there. This mountain was so steep that the houses which were built upon it seemed every moment ready to tumble down; but Dædalus enlarged the top, which he enclosed with a strong wall, and also consecrated to Venus Erycina a golden heifer, which so much resembled life that it seemed to exceed the power of art.

ERZERUM, the capital of one of the most considerable pashaliks in Armenia, of the same name, which is ruled by a pasha of three tails. It is surrounded on all sides by mountains, the highest peaks of which are covered with snow; and it lies in a valley beneath. The streets are in general paved, and the houses are built of stone, with rafters of wood and terraces. On the tops of these the grass grows, and they afford pasture for sheep; so that when seen from a distance they appear to form part of the plain in front of the town, which is about twenty miles in circumference, and is embellished with upwards of sixty villages. Towards the south the town is protected by a citadel, mounting twenty pieces of cannon of different calibres. It is surrounded by a double wall of stone, and has four gates covered with plates of iron. On the eastern face this work assumes a modern appearance, having regular embrasures; but, from its want of solidity, it is equally defenceless with any other part of the castle. In the eastern part of the city is an old brick tower, the loftiest building in the place, with a clock on the summit which strikes the hours with tolerable regularity. It contains forty-five mosques and two churches. Two of the most ancient of the mosques are beautifully ornamented with bricks and coloured tiles, which lofty domes, together with the glittering minarets of others, give a delusive appearance of splendour to the city when seen from a little distance, which totally vanishes on a nearer view. There are, besides, a Greek church and a large Arminian chapel; and at some distance from the city are three celebrated monasteries. The bazars are extensive, and well supplied with provisions, excepting fruit, which is brought by the Georgians from the province of Akiska, a distance of three or four days' journey. It has manufactures of considerable importance, and carries on an extensive trade in copper, and in articles from Persia, and from the countries to the north-west of Hindustan. In winter the cold is intense; it commences in August, and snow lies on the ground from October to March. The air is however pure, the water good, and the inhabitants in general healthy. The town was visited by the plague in 1807, which carried off a great number of the inhabitants. The population amounts, according to some, to 100,000 or 130,000, and consists of Turks, Greeks, Persians, and Armenians. Sir R. K. Porter's estimate is only 6000 Christians and 50,000 Mahommedans. It is two hundred and fifty miles north-north-east of Aleppo. Long. 40. 57. E. Lat. 39. 57. N.

ESARHADDON, the son of Sennacherib, and his successor in the kingdom of Assyria. He is said to have reigned twenty-nine years at Nineveh, from the year 3294 to 3322; besides which he reigned thirteen years at Babylon, making in all forty-two years. He died in the year of the world 3336, and was succeeded by Saosduchinus. Esarhaddon Sir Isaac Newton considers as the same with the Sardanapalus, who, according to Clectarchus, died of old age, after the revolt of Syria; the name *Sardanapalus* being derived from *Asserhadon Pul.*

ESCALADE, or SCALADE, an attack of a place without proceeding in form, or carrying forward regular approaches. It is usually made by means of ladders, which are employed for enabling the assailants to descend into the ditch, where such exists, and then to scale the rampart.

ESCHEAT, in *Law*, signifies any land or tenement that casually falls to a lord within the manor.

ESCHENBACH, a bailiwick of the circle of the Upper Maine, in the kingdom of Bavaria, extending 264 square miles. It contains two cities, three towns, 166 villages, and 2480 houses, with 15,316 inhabitants. The chief town, of the same name, once fortified, containing 180 houses, and 1056 inhabitants, employed in making linen cloth.

ESCHERSHAUSEN, a town in the Weser district of the duchy of Brunswick, on the river Lenne, containing, with Wickersen, 146 houses, and 1046 inhabitants. It is the capital of a bailiwick, which has 2030 houses, and 15,890 inhabitants.

ESCHEVIN, or ECHEVIN (*Scabinus*), in the French and Dutch polity, a magistrate elected by the inhabitants of a city, to manage their common concerns, and promote the good order, convenience, and decoration of the city.

ESCHRAKITES, or ESRAKITES, a sect of philosophers amongst the Mahommedans, who adhere to the doctrines and opinions of Plato. The word is derived from the Arabic *schraka*, which in the fourth conjugation signifies to shine or glitter like the sun, so that *Eschrakite* seems to signify illuminated.

The *Eschrakites*, or Mahommedan Platonists, place their highest good and happiness in the contemplation of the Divine Majesty, despising the sensual imaginations in the Koran concerning paradise. They are careful in avoiding all vice; they preserve an equal and easy temper, love music, and divert themselves with composing little poems or spiritual songs.

ESCHWEGE, a city of the province of Lower Hesse, in the principality of Hesse Casel. It is situated on the river Werra, and contains four churches, 782 houses, and 4845 inhabitants, employed in making cloth and tanning leather. It has some navigation on the Werra. In the vicinity a considerable quantity of tobacco is cultivated.

ESCOBAR, a town of Andalusia, in Spain, in the province of Jaen. It is situated on the declivity of the mountains of the Sierra Morena, near the descent of the river Jandula, which runs into the Guadalquiver.

ESCUAGE, in our old customs, a kind of knight-service, called *service of the shield*, by which the tenant was bound to follow his lord to the wars on his own charge.

ESCULENT, an appellation given to plants or roots which may be eaten; as beets, carrots, artichokes, leeks, onions, parsnips, potatoes, radishes, and the like.

ESCURIAL, a monastery and royal palace in Spain. It is situated to the north of Madrid, in a country the surface of which is covered with rocks, and where there is little shelter from the winds, which makes this elevated place very cold in the winter months. It is dedicated to St Lawrence, on account of Philip the Second having gained the battle of St Quentin, in 1557, on the day sacred to the memory of that saint. It is whimsically built in the form of the gridiron, on which that saint is said to have been broiled alive.

The cross bars of the gridiron, forming ranges of buildings, between which are courts, are inhabited by monks and ecclesiastics, and the pile of building which represents the handle is the royal palace.

The square part of the building is six hundred and forty feet in length, and five hundred and eighty in breadth. The projection which forms the royal palace is four hundred and sixty feet in length. It is about sixty feet in height, and at each angle is a square tower two hundred feet high. It is one of the largest, and perhaps one of the most tasteless, buildings in Europe.

The church, in the centre of this uncouth mass of stone, is very large, rich, and of a species of architecture calculated to fill the mind with awe on entering it. The high altar is most profusely adorned with marbles, agates, and jaspers, and the gold and silver furniture are of the most costly kind. The cupola which covers this church is the most correct object in the whole of the vast pile. The Pantheon, a repository beneath this church, is the place of interment for the royal family, the bodies of whom are deposited in tombs of marble placed in niches, one above another. The richest part of this palace, however, was that which contained the valuable pictures to be seen in almost every part of it, and which altogether formed the best collection of the productions of the first masters that any place in Europe displayed. We speak of what it was; for the French, when in possession of the Escurial, robbed it of some of its best treasures, and it is not accurately known what portion has been left in the place. The best productions of Reubens, Titian, Spagnoletti, Raffaelle, Baroccio, Velasquez, Murillo, and others, adorned this place, and were little known except by the descriptive catalogue, as very few travellers have heretofore visited Spain with a view principally to the contemplation of the fine arts.

The most valuable treasures of the Escurial are, however, the immense collection of ancient manuscripts which is preserved in the library of that place. Thousands of volumes of the Arabian writers are buried, and their names scarcely known, which, if carefully examined, would throw much light on the history of science and the arts at that period when the mind of Europe, emerging from the darkness of the middle ages, first began to develope those higher qualities, the improvement of which was prodigiously accelerated by the invention of printing, and the impulse which the reformation gave to the minds of men in all parts of Europe. It would be doing injustice to the literary character of Spain not to state that the learned societies of Madrid have, as far as their limited powers would admit, examined, classed, and described these treasures. Some of them have been translated into Latin, others into Castillian, and more attention was being given to the subject than it had previously attracted, when the irruption of the French suspended every pursuit that was not directed towards the purposes of warlike defence.

There are some good statues, busts, and medallions in the Escurial. That of St Lawrence, the patron, is very excellent, and said to be an antique; but some of the best of the Spanish artists have averred that the head was from an ancient statue of Bacchus, and the body of more modern workmanship, but nearly approaching in execution to the original portion. These kinds of treasures are, however, less valued by the monks who show the place, than the autographs of several of the saints, which, as they affirm, are preserved here, and certainly exhibited with great veneration, and implicit faith in their genuineness.

As this place has been chiefly occupied by the royal family for the sake of the sports of the field, for which the surrounding country affords ample means in game of every description, it has been generally inhabited during the winter months, when, from its exposed situation, it is a most uncomfortable place of residence. To obviate some of the evils of the situation, a town has been built near the monastery; but, like all forced operations of the kind, it has never flourished, and is now rapidly declining. The centre of the monastery, by accurate observations, is in west longitude 3. 37. 35. from London, and in north latitude 40. 35. 50.

ESCUTCHEON, or SCUTCHEON, in *Heraldry*, is derived from the French *escusson*, which is a corruption of the Latin *scutum*, and signifies the shield on which coats of arms are represented or emblazoned. Most nations, even from the remotest antiquity, were wont to have their shields distinguished by certain marks painted on them; and to be able to display these on their shields was a token of honour, none being permitted to have such until they had performed some honourable action.

ESDRAS, a Jewish priest, and doctor of the law. Artaxerxes Longimanus sent him with rich presents for the adornment of the temple at Jerusalem, which was rebuilt under Zerubbabel; and the king also ordered the neighbouring governors to provide him with whatever might conduce to the pomp of the Jewish religion, as well as to the exemption of the priests from paying taxes. He is supposed to have been the collector of the canon of Scripture, and to have added by divine inspiration some things which happened after the deaths of the authors. It is conjectured that he wrote the Chronicles, besides those books which bear his name, the last two of which are exploded even by the church of Rome.

ESHER, a town of Surrey, in the hundred of Elmbridge, on the road to Portsmouth, seventeen miles from London. An ancient palace of the bishops of Winchester, but which has been celebrated as the residence of Wolsey, continues in a modernized form to be an object of attention, but especially its park, through which meanders the river Mole. The population in 1801 amounted to 846, in 1811 to 951, in 1821 to 1108, and in 1831 to 1215.

ESK, the name of several rivers both in England and Scotland, particularly of one which forms part of the boundary between the two kingdoms. It runs from north-east to south-west, and gives name to the district of Eskdale.

ESKI-HISSAR, a small town of Asiatic Turkey, in Natolia. It is supposed to stand on the site of the ancient Stratonica, which was founded by a colony of Macedonians. The neighbouring plain is fertile in tobacco, which is collected by the inhabitants, who hang it up in their cottages to dry. It is situated sixteen miles westward from Mogla.

ESNE, or ESNEH, a considerable town of Upper Egypt. "Esneh," says Denon (*Travels*, ii. 103), "is the ancient Latopolis. Some remains are still visible of its port or quay on the bank of the Nile, which has often been repaired, but, notwithstanding all that has been done for it, still remains in a very miserable condition. This town also contains the portico of a temple, which appears to me to be the most perfect monument of ancient architecture. It is situated near the bazar in the great square, and would make an incomparable ornament to this spot, if the inhabitants had any idea of its merit; but instead of this, they have deformed it by the most miserable ruined hovels, and have devoted it to the vilest purposes. The portico is very well preserved, and possesses great richness of sculpture. It is composed of eighteen columns with broad capitals: these columns are noble and elegant, though they now appear in the most disadvantageous light: the rubbish should be cleared to find if any part of the *cella* remains." See article EGYPT.

ESPALIERS, in *Gardening*. See HORTICULTURE.

ESPALION, an arrondissement of the department of the Aveiron, in France, extending over 639 square miles. It is divided into nine cantons and 101 communes, and contains 63,376 inhabitants. The capital is a city of the same name, situated on the river Lot, on which are some mills for spinning cotton, and establishments for curing various kinds of leather. It contains 2038 inhabitants.

ESPLANADE, in *Fortification*, is the sloping of the parapet of the covered-way towards the field, and the same as the glacis of the counterscarp; but it has become in a great measure antiquated in this sense, and is now only applied to the empty space between the glacis of a citadel and the first houses of the town.

ESPOUSALS, in *Law*, signify a contract or promise made between a man and a woman to marry each other; and in cases where marriages may be consummated, espousals take place previously. Marriage is termed an espousal *de præsenti*.

The espousals amongst the Jews were either by writing, or by a piece of silver given and received, or by cohabitation. Amongst the Greeks, after the parents and friends of the young people had finished their negotiation, the couple themselves pledged their faith to each other; the man swearing that he would be constant and true, the woman that she would marry him, and make him master of all she had. They then ratified their agreement by a kiss and by joining right hands.

Amongst the Romans the espousals consisted in an engagement of friends on both sides, whether absent or present, in public or without witnesses. But the common way was by means of writings drawn up by common consent, and sealed by both parties; and besides this, the man sent a ring to the woman, consisting of iron, and without a stone.

ESQUIMAUX, a people of North America, inhabiting the vast tract of land known by the name of *Labrador*. They differ very considerably, both in aspect and manners, from the other American nations, and agree in most respects with the inhabitants of West Greenland.

ESQUIRE (from the French *escu*, and the Latin *scutum*, in Greek *σκυτος*, which signifies a hide, of which shields were anciently made, and with which they were afterwards covered) was originally he who, attending a knight in time of war, carried his shield; from which circumstance he was called *escuier* in French, and *scutifer* or *armiger* in Latin.

It is a matter somewhat unsettled, says Blackstone (b. i. ch. 12), what now constitutes this distinction, or who is a real esquire; for it is not an estate, however large, that confers this rank upon its owner. Camden, he adds, distinguishes them the most accurately, and he reckons four sorts of esquires: 1. The eldest sons of knights, and their oldest sons, in perpetual succession; 2. The eldest sons of younger sons of peers, and their eldest sons, in like succession; 3. Esquires created by the king's letters patent, and their eldest sons; 4. Esquires by virtue of their office, as justices of the peace, and others bearing any office of trust under the crown.

ESSAY, a trial or experiment for proving the quality of any thing; or an attempt to ascertain whether or not any invention will succeed.

ESSAY, in *Literature*, a peculiar kind of composition, the character of which is freedom, ease, and natural simplicity, without being confined to strict order and method, or worked up and finished like a formal system.

ESSAYING, or ASSAYING. See ASSAYING.

ESSEDARII, a sort of gladiators, mentioned by Seneca, Suetonius, and Cicero, who on some occasions engaged one another from chariots called *esseda*. The *essedum* was a sort of heavy chariot from which the Gauls and Britons engaged the Romans. See GLADIATOR.

ESSEN, a city of the Prussian province of Cleeve-Juliers, the capital of a circle of the same name. It is situated on the river Berne, is surrounded with walls, and contains two Catholic, a Lutheran, and a Reformed church, with 799 houses, and 5100 inhabitants, employed in making ironmongery articles, especially coffee-mills and cards for dressing cloths. Near to it are some very valuable coal-mines. Long. 6. 56. 1. E. Lat. 51. 27. 49. N.

ESSENCE, in *Metaphysics*, that which constitutes the particular nature of each genus or kind, and distinguishes it from all others.

ESSENES, or ESSENIANS, in Jewish antiquity, one of the three ancient sects amongst that people. They believed in a future state, but denied a resurrection from the dead. Their way of life was singular, inasmuch as they did not marry, but adopted the children of others, whom they bred up in the institutions of their sect, and, despising riches, had all things in common, never changing their clothes till these were entirely worn out. When initiated, they were strictly bound not to communicate the mysteries of their sect to others; and if any of their members were found guilty of enormous crimes, they were expelled. Pliny tells us that they dwelt on the western side of Lake Asphaltites; that they were a solitary kind of men, living without women or money, and feeding upon the fruit of the palm-tree; and that they were constantly recruited by new-comers, whom ill fortune had made weary of the world. The reason why we find no mention made of them in the New Testament may be their recluse and retired way of life, no less than their great simplicity and honesty, in consequence of which they did not lie open to censure or reproof.

ESSENTIAL, something necessarily belonging to a thing, and from which it cannot be conceived as distinct. Thus the primary qualities of bodies, such as extension, figure, number, and so on, are essential or inseparable from them in all their changes and alterations.

ESSENTIAL OILS are such as are really contained in a plant, and are drawn from it by distillation. They are so called in contradistinction to empyreumatic oils.

ESSEQUIBO, a river of English Guiana, in South America, which discharges its waters into the Atlantic. Long. 58. 30. W. Lat. 7. N. At its mouth it is twenty miles broad, but of difficult navigation, even for small vessels, on account of the numerous sand-banks which run in different directions across its entrance. There are three islands at the mouth of the river, and for nearly thirty miles upwards there is a succession of islands. The influence of the tide is felt for a hundred miles up the river.

ESSEQUIBO, a settlement of Guiana, on the banks of the above-mentioned river. The country is well cultivated and flourishing, the soil being fertile in the production of coffee, cotton, cocoa, and sugar. Essequibo originally belonged to the Dutch, and was first settled in 1698; but an erroneous prejudice that the land was unfit for cultivation obstructed the progress of the colony for many years. Political struggles, and the injudicious policy of the mother country, also for a considerable time deprived the colonists of the advantages which the country presented to them. During the American war it more than once changed masters, but it was finally ceded to Great Britain at the peace of 1814, since which period it has advanced in prosperity. It is separated on the west from Demerara by the small river Borasierri.

ESSEX, a county of England, is bounded on the south by the river Thames, on the east by the German Ocean, on the north by the counties of Suffolk and Cambridge, and on the west by Hertfordshire and Middlesex. Its surface contains 1473 square miles, according to the last measurement of the Board of Ordnance. The population has not increased in this county at the same rapid rate as that of the other counties of England, having been 226,437 in 1801, 252,473 in 1811, 289,424 in 1821, and 317,200 in 1831. As the surface is about 942,720 acres, there is nearly one person to every three acres; but if the rivers and large estuaries be deducted from the calculation of extent, the population may be stated as still more dense.

Essex may be considered as a mere agricultural county; for though, from the near approach of one part of it to the metropolis of the kingdom, there are some manufactories established, which find both their raw materials and their consumption in London; and though in one district of the county there are remains of the once extensive manufactories which were brought from Flanders to this island; the number of persons occupied in them bears but a very small proportion to that part of the population which depends on agriculture. The former manufactures of Colchester baizes for the Spanish and American markets have wholly disappeared, and those for woollen goods at Bocking, Halsted, and Coggeshall, are nearly extinct; all having removed to the northern parts of the kingdom. On the eastern side of the county, in the vicinity of the metropolis, are several large distilleries, and some establishments for bleaching and printing calicoes. There are also manufactories of sal-ammoniac, of Prussian blue, of iron liquor for calico-printers, and some other chemical preparations. There is a considerable trade in corn, and much barley is malted for the great breweries and distilleries. The only other commerce is that of supplying the inhabitants with foreign and domestic articles of luxury.

Although nearly half the county is bounded by the sea, or by navigable rivers, it carries on no foreign commerce; and what vessels belong to it are employed either in conveying to London the produce of its agriculture, or in the oyster fishery, which occupies a considerable tonnage and many seafaring persons. The oysters are bred both in the river Coln and in the Crouch; in the former they are protected by the seignorial rights of the corporation of Colchester, and in the latter by the proprietor of that river, Sir Henry Mildmay. The spawn is deposited in the months of April and May; and it is said the shell about it begins to form within twenty-four hours. The fishermen are forbidden to dredge for them at this season. In the month of July the dredgers separate the small oysters from the stones on which the spawn was deposited, and on which they have grown, and lay them down in the channels of the river till they grow of a size fit for consumption, which is determined by a gage kept for that purpose by the water-bailiff of Colchester. The stones or other substances to which the young oysters had adhered are again thrown into the water whence they were taken, as it is apprehended the accumulation of the ouse at the bottom of the river would otherwise generate such an increase of muscles and cockles as would destroy the breed of oysters. The number of vessels of different sizes employed in this branch of industry, from ten to forty tons burden, amounts to nearly three hundred, and the quantity of oysters caught, varying in different years, is from 18,000 to 24,000 bushels. The larger description of vessels are employed during part of the year on the shores of Hampshire and Dorsetshire in dredging for the native oysters, which are afterwards deposited in the beds of Essex and Kent, in order to fatten for the London market. The uncertain produce of the breeding grounds in Essex makes it necessary to have recourse to the more distant coasts to obtain the requisite supply.

From being almost wholly an agricultural county, the far greater part of the inhabitants of Essex are found in villages. The principal places, with their population, according to the late census, is as follows:

Colchester	16,167
Chelmsford	5,435
Walthamstow	4,258
Harwich	4,297
Saffron-Walden	4,762
Halsted	4,637
Romford	4,294
Maldon	3,831
Bocking	3,128
Coggeshall	3,227
Barking	3,404
Braintree	3,422
Waltham Abbey	4,104

Besides these, the towns of Witham, Dunmow, Harlow, Prittlewell, Finchingfield, Sible-Hedingham, Hornchurch, and Thaxted, each now contain more than 2000 inhabitants.

The face of the county is generally very beautiful; it is well enclosed, and for the most part displays good verdant pastures; the hills, none of which rise to great heights, are cultivated to the tops; and there are abundance of trees, especially oak and chestnut, which give a rich appearance to the view. There is no county in England in which the proportion of waste land is so small. The forests and wastes can indeed scarcely be considered as utterly uncultivated, and the whole of them do not amount to more than 14,000 acres, including the two forests of Epping and Hainault. These belong to the crown, though the inhabitants of many surrounding parishes have the right of pasturing their cattle upon them. The king has an unlimited right to keep deer on all the enclosed woods, and the occupiers of land in the various parishes included within the ancient boundaries of the forests have a right to feed horses and cows, but not other cattle. The numerous common rights have led to considerable devastation of the timber of these forests, and occasioned no small injury to the property of the crown; but plans have lately been adopted for preserving the trees, and converting a part into a nursery for growing timber for the royal navy. The vicinity to navigation makes these forests well deserving of being appropriated to this purpose.

That part of Essex which lies on the banks of the Thames, and on the shores of the ocean, is a rich alluvial soil on a subsoil of very tenacious clay. It produces, with good cultivation, most abundant crops of wheat, beans, oats, and clover. It is found necessary to the cultivation to fallow very frequently, and repeated ploughings is a practice very generally adopted. The swing plough is much used, and sometimes a wheel plough drawn by two, and occasionally by three horses abreast, which are guided with long reins by the ploughman. In fallowing it is common to plough the land six or seven times, and it is not unusual with the best cultivators to plough it eight or even ten times. After the summer fallow, by which the soil becomes completely pulverized, and rendered as fine as a garden, it is sometimes the practice to sow wheat in the autumn; but it is more common to let it remain throughout the winter, and then, after a spring ploughing, to sow barley or oats. The rotation of crops which usually succeed to a fallow is, 1. barley or oats; 2. clover, red or white, mostly the former; 3. wheat; 4. beans, twice hoed at least; 5. wheat. After this course the land is again fallowed. The whole produce of the course of crops is said to depend on the accuracy and skill exercised in the process of fallowing.

There is in this district some land adapted for turnips, and the rotation on such soils is usually, 1. turnips; 2. oats or barley; 3. clover; 4. wheat; 5. beans; 6. wheat. These courses are occasionally varied, tares being introduced when the clover fails, and peas being sometimes substituted for beans. The best cultivators often omit the second crop of wheat, and fallow again after the beans. A rotation which is sanctioned by some very skilful agriculturists is the following: 1. fallow; 2. barley or oats; 3. clover; 4. beans; 5. wheat; 6. tares or peas; 7. wheat. In this case the manure is laid on the clover ley for the bean crop. In the district we are describing all the farms have a portion, more or less extensive, of rich marsh land, on which oxen are fed, which supplies hay for winter consumption, and is consequently the source whence the manure is derived. The best wheat that is brought to the market of the metropolis is raised in the part of Essex of which we are speaking, and which is usually denominated the *hundreds*. It has the convenience of water-carriage to London; the rent of land is comparatively low, and it is of extraordinary fertility; but it suffers from a scarcity of good water. It is, especially in the autumn, a very agueish county; and though of late the roads have been much improved, they are still in such a state as, added to its insalubrity, prevents the gentry from residing on their estates.

The middle part of Essex rises above the level of the marshy lands, but partakes, in a considerable degree, of their unhealthiness. Around the town of Colchester, for a considerable distance, the soil is a dry loam, well calculated for turnips; and then the most general system adopted is the four-course husbandry of Norfolk, viz. turnip, barley, clover, and wheat. A variation is in some instances introduced by taking a crop of peas after the wheat, and occasionally tares are sown after the barley instead of clover, as that latter plant will sometimes fail if too frequently repeated. The greater part of the district is, however, of a clayey loam, on a subsoil of clay, and too tenacious for the turnip system. Much of this is good old pasture land, used solely for feeding, and to which the plough is never applied. The arable land is highly productive; the crops of wheat and beans especially are very luxuriant, and their produce of the best quality. The practice of fallowing is pursued as in the district before described, but so many ploughings are not deemed necessary. The rotation is various, but it rarely occurs that wheat is sown immediately after the fallow. Most commmonly the succession is as follows: 1. fallow; 2. barley; 3. beans; 4. wheat; 5. tares; 6. barley; 7. clover. When the land is more wet, which, in spite of excellent draining, is frequently the case, the rotation is, 1. fallow; 2. oats; 3. clover; 4. wheat. When manure is abundant, the heavy soils are cropped in the following rotation with great success: 1. fallow; 2. beans; 3. wheat; 4. tares; 5. barley; 6. clover; 7. beans; 8. wheat. In this rotation the clearing of the ground from weeds depends on the use of the hoe, which is applied most carefully to the crops of beans.

The western part of the county, especially where it borders on Hertfordshire, is, in general, land of a very inferior quality, and, without very expensive cultivation, yields but light crops. In one extensive district, called the Rodings, is still practised a most singular system of husbandry, known now in Essex only, though formerly it was adopted on poor lands in some other counties. It is, 1. a year's fallow; 2. wheat; 3. fallow; 4. barley, and then a repetition of the same course; thus having one half the arable land constantly without any crop. The soil is a tenacious clay, of a reddish colour, upon a subsoil of white clay. It is difficult to pulverize, and, with wet, potches so much as not to admit of ploughing when the atmosphere is moist. There are but small parts of this district which produce clover, peas, tares, or beans; and what hay is grown is confined to the narrow borders of the rivulets which run in the valleys.

In the south-western part of the county the agriculture assumes that system which is adapted to the supply of the wants of the metropolis. A great portion of the land is in permanent pasture, or grows hay to furnish the markets of Smithfield and Whitechapel. The arable land is generally cultivated with a rotation of three crops, viz. potatoes, wheat, and clover; and, as London supplies abundance of manure, by applying it very liberally to the young clover, after the wheat is harvested, such culture produces most abundant crops, and the land is cleaned by the potato culture. In this kind of husbandry, which, indeed, can only be conducted where manure is to be obtained with great facility, the plough is only used once in the rotation after the clover; as the potatoes are planted, and the digging them up sufficiently prepares the land for wheat.

Essex feeds some sheep, but very few are bred in the county. Calves are suckled to a great extent, and the rearing them to furnish veal for the London market is the principal dependence of many farmers. The whiteness of the veal is produced by a great attention to cleanliness, by regular periods of suckling, and by giving them a small portion of barley-meal mixed with chalk. The tendency to fatten is promoted by administering narcotic drugs, which keep the young animals in a quiescent state. Though the county affords such abundance of excellent pasture, yet the fattening of calves is so much more profitable than the dairy, that it is supplied with butter from other counties. Epping has indeed been celebrated for its excellent butter; but the greater part of what is sold in London under that denomination is the produce of Northamptonshire, Buckinghamshire, and other counties. London is supplied with much of its beef from Essex. The bullocks, in a lean state, are brought from Scotland, from Wales, and some from Devonshire, and are fattened in this county, sometimes on the rich natural meadows, and sometimes on turnips, with the addition of oil-cake.

Several other agricultural productions are cultivated in Essex. Hops are grown near Chelmsford, and in a few other districts. Saffron is cultivated near Saffron-Walden with great success. Mustard is an advantageous crop in the islands of Foulness and Wallasea, and on the embanked marshes. On some rich old pasture land, when first broken up, three crops are raised together, viz. carraway seed, coriander seed, and teasels for the baize manufacturers. The three kinds of seed are sowed together in the spring of the year. The harvest of the coriander takes place in the following autumn. The carraway is a biennial plant, and the seed is fit to be gathered in July of the succeeding year; and in September of the same year the teasels are cut. The carraway sometimes produces a crop the second, or even the third year. This cultivation is deemed an excellent preparation for the growth of wheat, on lands which are so prolific as to require some degree of exhaustion, as, the hoe being very liberally applied in the process of this triple cropping, it keeps the ground free from weeds. There are few counties in England, taking the whole of them together, in which the agriculture is so skilfully conducted, or where the productiveness is so great.

The landed property in Essex, as in other counties near to the metropolis, is very much divided; there are no overgrown estates, though some of considerable value, belonging to a few individuals; but the greater part is in moderate-sized farms, which can be easily disposed of, and which are frequently purchased from the savings of the commercial class in London.

The only good harbour in this county is Harwich, whence the packets for Holland are dispatched, and where there is a royal dock-yard, in which some frigates are built and repaired. The river Coln is navigable for small vessels to Colchester, and the Blackwater river to Walden. The Crouch is navigable for the largest ships; but, passing through an unhealthy country, and having few inhabitants on its borders, it is useless for the purposes of commerce. The river Lea is navigable by barges a distance of twenty-five miles. There are no canals in this county, but one is projected to unite the river Lea with the Cam, and thus create internal navigation from Lynn to London.

This county gives the title of earl to the family of Capel, and of Rochford to the family of Nassau; that of Baron Colchester to the family of the late Speaker of the House of Commons, Abbot; and that of Baron Western to the late representative of the county.

The members of the House of Commons elected in Essex are ten, being two for each of the boroughs of Colchester, Harwich, and Maldon, and four for the county, which, for election purposes, has been divided into the northern and southern districts. The polling places of the former are Braintree, Colchester, Saffron-Walden, and Thorpe; and of the latter, Chelmsford, Billericay, Romford, Epping, Rochford, and Maldon.

The most remarkable seats of noblemen and others are Audley-End, Lord Braybrooks; Thorndon, Lord Petre; Wanstead, now dilapidated, Hon. William Wellesley Pole; Easton Lodge, Lord Maynard; Felix Hall, Lord Western; Mistley Hall, C. Manners Sutton; Dagenham Park, Sir Thomas Neave; the Hyde, Theo. Disney, Esq.; Chigwell, Sir Eliab Harvey; Hill Hall, Sir William Smyth; Cranham Hall, Lady Davy; Weald Hall, Christopher Tower, Esq.; Boreham House, Sir John Tyrell; Coped Hall, Mr Conyers; Mark Hall, Mr Arkwright; Stansted Hall, Mr Fuller Maitland; and many others.

Essex, a post-town in Essex county, New York, on the western shore of Lake Champlain. It is fourteen miles south-west of Burlington, and sixteen miles from Elizabethtown. In this township there is a village situated on the lake, which is very flourishing, and enjoys a considerable trade. Essex is the name of several counties in the United States, which will be found described as they occur under the heads of the respective states.

ESSLINGEN, a city of the circle of the Neckar, in the kingdom of Wirtemberg, capital of a bailiwick of the same name. It is situated on the river Neckar, in a fertile district, and contains five churches, 980 houses, and 5591 inhabitants, who carry on woollen and cotton manufactures by machinery. Long. 9. 13. 25. E. Lat. 48. 44. 27. N.

ESTAIRES, a city of France, in the department of the North, on the navigable river Lys. It is an ill-built manufacturing town, producing table-linen, lace, and other goods, with 557 houses, and 5913 inhabitants.

ESTACHAR, Estaker, or Istakhar, a town of Persia, in the province of Kuzistan, near to which are the ruins of the celebrated city of Persepolis. It is thirty miles north-north-east of Schiraz, and 160 south-south-east of Ispahan. Long. 53. 40. E. Lat. 30. 5. N.

ESTAMBOLIC, or Istambel, a town of Arabia, in the jurisdiction of the schereef of Mecca, near the coast of the Red Sea. It is 180 miles north-north-west of Medina.

ESTATE, in *Law*, signifies the title or interest which a person has in lands, tenements, or other effects. A fee-simple is the amplest estate the law admits of.

Estates, in a political sense, is a term used to denote either the dominions of some prince, or the general classes into which the people are divided.

In Britain, the estates are the king, lords, and commons; or rather the lords and commons, who meet the king in parliament, for the purpose of reforming abuses, and enacting good and wholesome laws.

ESTE, a city of Italy, in the Austrian government of Venice, situated on the canal of Monfelice. It is fortified, and contains a cathedral, several palaces, and 7534 inhabitants, who carry on a brisk trade in spinning silk and making silk goods. It is rich in antiquities, and is the place whence originated the family which at present sits on the British throne. Long. 21. 25. 30. E. Lat. 45. 31. 21. N.

ETAWEH, a town and fortress of Hindustan, in the province of Agra, and capital of a district of the same name. It is situated on the eastern bank of the Jumna, many parts of which, during the dry season, are sixty feet in height. The town is built on the heights, and, as it approaches the river, is divided into separate hills by deep ravines. It was formerly the residence of a rajah, and a place of considerable consequence; and it still carries on a considerable traffic in grain, sugar, and cotton. There is also an extensive manufacture of coarse cotton cloths in the vicinity. It is now the station of the civil establishment of the district. Long. 78. 58. E. Lat. 26. 46. N. The district is situated in the Doab, or between the Ganges and the Jumna, and about the 27th degree of north latitude; and, with the rest of the Doab, it was ceded to the British by the nabob of Oude in 1801.

ESTELLA, a city of Spain, upon the Ega, in the province of Navarre, containing 4600 inhabitants. It possesses an old castle and a college. Many distilleries of brandy and wine are carried on here, as well as a manufactory of cloth, which supplies the army.

ESTEPONA, a small town on the shores of the Mediterranean Sea, in the province of Granada, in Spain. It contained nearly 5000 inhabitants before the ravages of the epidemic fever in 1804, which almost desolated the coast on which it stands. On this occasion it lost one third of its inhabitants. The principal occupation of the people consists either in fishing, or in cultivating fruits of various kinds, and conveying them to the British garrison of Gibraltar; in making earthenware and bricks; and in the manufacture of linen, which employs twenty looms.

ESTHER, a canonical book of the Old Testament, containing the history of a Jewish virgin, dwelling with her uncle Mordecai at Shushan, during the reign of Ahasuerus, one of the kings of Persia. The great beauty of this Jewish maiden raised her to the throne of Persia, by which means she had an opportunity of saving her countrymen, whose destruction had been plotted by Haman, a favourite of Ahasuerus.

The learned are not agreed as to who this Ahasuerus was. Archbishop Usher supposes him to have been Darius Hystaspes, and Artystona Esther. Scaliger makes him the same with Xerxes, and supposes his queen Hanestris to be Esther; but Josephus, on the contrary, positively asserts that the Ahasuerus of the Scriptures is the Artaxerxes Longimanus of profane history; and the Septuagint, throughout the whole book of Esther, translate Ahasuerus by Artaxerxes. Most people subscribe to this last opinion; and indeed the kindness which Artaxerxes showed to the Jews can scarcely be accounted for otherwise than by supposing that that people had so powerful an advocate as Esther to plead in their behalf. It may be observed, however, that the ancient Persians, who were singularly intolerant of idolatry, and the fierce destroyers of idols, wherever such were to be found, might, for this reason, be supposed favourable to a people whose religion admitted not graven images, and who, like themselves, were pure theists.

ESTHONIA, or ESTHLAND, a province of the Russian empire, on the Baltic Sea, extending over 7106 square miles. It is divided into four circles, viz. Revel, Hapsal, Weisenstein (formerly Jerwen), and Wesenburg (formerly Wierland). It contains five cities, one market-town, forty-seven parishes, and 630 estates of nobles, with 30,000 peasants' dwellings. The whole population amounts to 412,000 persons. It is a level and generally a sandy district, but mixed with portions of clay and stones. It is full of brooks and morasses. As agriculture is the chief employment, the land produces rather more corn, chiefly rye, than is required for the consumption. The fishery occupies a number of hands. The manufactures are of a domestic kind; and, during the long winters, coarse linen and woollen cloths are spun and woven for their own clothing in each family. The capital, Revel, is the chief place of foreign trade, from which is exported corn, spirits, butter, salted fish and flesh, and tallow, with a small quantity of flax and flax seed.

ESTOILEE, or CROSS ESTOILLEE, in *Heraldry*, a star with only four long rays in the form of a cross, and accordingly, broad in the centre, but terminating in sharp points.

ESTOPPEL (from the French *estouper*, *oppilare*, *obstipare*, to stop or block up), in *Law*, an impediment or bar of action, arising from a man's own act or deed.

ESTREMADURA, a province of Spain. It is bounded on the north and east by New Castille, on the south by Andalusia, and on the west by Portugal; the southern part being divided from that kingdom by the river Guadiana. It is the most thinly peopled of any part of the kingdom except Cuença, and the density of its population very little exceeds that province. Its extent is 1199 square leagues, and its population amounts to 428,493 souls. The soil in general is fruitful, and produces vines, oil, hemp, silk, corn, and fruits. Its mountains abound in chestnuts, in oaks, and the other timber trees. Its pastures feed large flocks of sheep, both of the migratory and fixed breeds. The breeds of horses are excellent; and the pigs are celebrated throughout Spain, the hams and sausages made from them being preferred to all others. In spite however of the capacity to yield these valuable productions, much of the land is uncultivated, and many parts of it are without inhabitants. The backward state of the agriculture is generally attributed to vast tracts of land, susceptible of the best cultivation, being destined solely to the pasturage of the Merino flocks. As the pastoral life requires but few labourers, and extensive open fields, where sheep flocks are managed so very injudiciously as they are in Spain, it has a tendency to check the increase of population and cultivation. The northern part of this province extends to the banks of the Tagus, into which, after their junction, run the two rivers of that district. These are the Xerte and the Alagon. The middle of the province, between the upper part of the Guadiana and the Tagus, is a very dry country, with no great and few small streams. The southern part has the river Guadiana, a muddy and often stagnant stream, and some tributary rivers. It is the best cultivated part, but between it and Seville are ranges of mountains, which hold out little inducement to any other system of farming than that of feeding sheep for the sake of their valuable fleeces. There are some mines of silver and of platina in this southern division of the province. The yearly produce of this province is 6000 cwt. of pepper, 5925 of flax, and 875 of hemp; of wine 4376, of brandy 53,125, of vinegar 1000 ohms; of oil 50,259, of sumach 9800, of madder 45, of woad 100, and of silk 204½ cwt. The annual produce of honey is 3375, and of wax 600 cwts. In manufactories of cloth there are employed 726, and of linen 2168 looms. There are also 155 tanneries, twenty-five hat manufactories, and seventy-three soap-boiling houses.

ESTREMADURA, a province of Portugal, the only one in that kingdom which does not in some of its borders join to Spain. Though Lisbon and its great population forms part of this province, it is not so thickly peopled as either Entre-Douro-e-Minho or La Beyra. Its extent is 823 square leagues, and its inhabitants amount to 826,680 souls. The province of La Beyra surrounds Estremadura, excepting where the sea or the river Tagus are its limits. The soil produces some wheat, maize, and millet, much wine and oil, and abundance of fruits and culinary vegetables. Its shores abound with fish, as well as the fresh-water rivers. On the coast great quantities of salt are made by the evaporating power of the sun alone, and consequently much cheaper and better than in our more northern climate. The only river besides the Tagus that runs into the sea is the Lis, which empties itself near Leyria. The Tagus, which crosses Estremadura, has its course so interrupted by rocks and cascades, as to be incapable of navigation above Abrantes; but from that city to Lisbon, a distance of thirty leagues, shallops regularly navigate. The right bank, after the Tagus enters Portugal, is mountainous; but the left bank is marshy, sterile land. From Santarem there is a constant gradual declivity to the city of Lisbon, and, though fourteen leagues asunder, the capital may be seen from the former city. The rivers which from the north increase the waters of the Tagus, are the Pouzut, the Lysa or Laca, and the Cecere. These descending from the mountains of La Beyra, have an unequal and sometimes dangerous degree of rapidity, being at one time mere rivulets, almost dry, and at others rapid torrents, which inundate the country; but when they do so, they afford means of defence against an invading enemy. Some ranges of high mountains run northward from the Tagus towards Busaco. One spot in these will be long celebrated. The lines of Torres Vedras will not be forgotten as the place where Lord Wellington made his successful stand, and caused to roll back on the invaders the desolation they had spread in their advancing course.

ESZEK, a city of the Austrian kingdom of Hungary, in the province of the Farther Theiss, and the capital of a circle of its own name. It is situated on the river Drave, is strongly fortified, and defended by a citadel. It is a place of considerable trade in corn, cattle, and hides, and contains three Catholic and one Greek church, with 10,850 inhabitants. Long. 18. 36. 45. E. Lat. 45. 34. 13. N.

ETAMPES, an arrondissement of the department of the Seine and Oise, in France, extending over 380 square leagues, divided into four cantons and 101 communes, and containing 37,922 inhabitants. The capital, of the same name, is situated on the river Juine, in a most delightfully fruitful neighbourhood. It contains 982 houses, and 7198 inhabitants, who make hats, caps, and hosiery, and dress much leather. Long. 2. 1. E. Lat. 48. 25. N.

ETCHING, a method of engraving on copper, in which the lines or strokes, instead of being cut with a tool or graver, are eaten in with aquafortis. See ENGRAVING.

Etching, though not very modern, is of later invention than engraving with the tool, of which it was at first only an imitation, practised by painters and other artists, as they could much sooner form their hands to, and attain a facility of, working in this way than with the graver. But being nevertheless considered as a counterfeit kind of engraving, and therefore inferior to the other, it was cultivated in a very confined manner; the closeness of the resemblance of the work to that performed by the tool being made the test of its merit, and consequently the principal object of aim in those who pursued it. This servile restriction of the art of etching to the imitation of the original kind of engraving was a great cause of retarding its advancement towards perfection, as many of the most able masters cramped their talents by the obser-ance of so narrow a rule. This may be seen in the instances of Sadelers, Swaneberg, Villamena, and particularly Le Bosse, who, in his treatise on engraving, has laid it down as a principle, that the perfection of this kind consists in the close similitude of the work to that executed with the tool. But this absurd prepossession has been since worn out; and the method of working with aquafortis has been so far improved, that instead of being now deemed a spurious kind of engraving, it evidently appears, in many modern works, the foundation of an excellence that could never have been produced without it; since, though the neatness and uniformity of the hatches which attend the use of the tool is more advantageous with respect to portraits, yet the liberty and facility of the other manner gives a much greater opportunity to exercise the force of genius and fancy in historical engraving, where the effect of the whole, and not the minute exactness in finishing all the parts, constitutes the principal value.

There are two methods practised of engraving in this way; the one with a hard varnish or ground, and the other with a soft. The former was at one time much used, being better accommodated to the intention of imitating the engraving with the tool; as the firmness of the body of the varnish gave more opportunity of retouching the lines, or enlarging them with the oval-pointed needles, called by the French *echoppes*, as was practised by Le Bosse and others for that purpose. The latter has now almost wholly superseded the use of the other, by the free manner of working it admits of; which affords a power of expression incompatible with the greater inflexibility of the hard varnish, that confines the lines and hatches to such a regularity and sameness, as give stiffness of manner and coldness of effect to the work.

The combination of the use of the tool and aquafortis, which are now both employed in many cases, has, however, given that perfection to engraving which it at present possesses. The truth and spirit of the outline which the method of working with aquafortis affords, and the variety of shades which the different kinds of black produce in this way, as well as other means of expressing the peculiar appearance and character of particular subjects, furnish what was defective in the sole use of the tool; whilst, on the other hand, the exactness and regularity of the lines, which are required for finishing many kinds of designs, are supplied by the graver; and by a judicious application of both, that complete finishing is obtained which either of them alone must necessarily want.

The manner by which this is performed, is by covering the surface of the plate with a proper varnish, or *ground*, as it is called, which is capable of resisting aquafortis, and then scoring or scratching away, by instruments resembling needles, the parts of this varnish or ground, in the places where the strokes or hatches of the engraving are intended to be; then, the plate being covered with aquafortis, the parts which are exposed by removing the ground or varnish are corroded or eaten away by it, whilst the rest, being secured and defended from the action of the acid, remain untouched.

There are two methods of etching, as has been already observed, the difference of which consists as well in the kind of the varnish or ground as in that of the aquafortis adapted to each kind; but the general methods of performing them are alike in both cases. These varnishes or grounds are distinguished by the names of *hard* or *soft*; for in their consistence, or the resistance which they give to the needles, lies their essential variation from each other. The hard varnish, it is with good reason conjectured, was not the first in use, but soon took the place of the other, and was for some time the most received in practice, on account of its admitting the work to be made more like that of the graver; the soft has since, however, in its turn prevailed, to the exclusion in some degree of the hard, except in the case of particular subjects, but not so entirely as to take away the expediency of showing how it is performed. The manner of etching with the soft varnish is now, however, one of the most important objects of the art of engraving; and it is at present in universal use, sometimes alone, but more frequently intermixed with the work of the tool, and in some cases with great advantage, even where the whole is intended to pass for being performed by the graver.

Preparation of the soft varnish, according to Mr Lawrence, an eminent English engraver at Paris.—"Take of virgin wax and asphaltum each two ounces, of black pitch and Burgundy pitch each half an ounce. Melt the wax and pitch in a new earthenware glazed pot, and add to them, by degrees, the asphaltum, finely powdered. Let the whole boil till such time as that, taking a drop upon a plate, it will break when it is cold, on bending it double two or three times betwixt the fingers. The varnish, being then enough boiled, must be taken off the fire, and, letting it cool a little, must be poured into warm water, that it may work the more easily with the hands, so as to be formed into balls, which must be rolled up, and put into a piece of taffety for use."

It must be observed, first, that the fire be not too violent, for fear of burning the ingredients, a slight simmering being sufficient; secondly, that whilst the asphaltum is putting in, and even after it is mixed with them, the ingredients should be stirred continually with the spatula; and, thirdly, that the water into which this composition is thrown should be nearly of the same degree of warmth with it, in order to prevent a kind of cracking that happens when the water is too cold.

The varnish ought always to be harder in summer than in winter; and it will become so if it be suffered to boil longer, or if a greater proportion of the asphaltum or brown resin be used. The experiment above mentioned, of the drop suffered to cool, will determine the degree of hardness or softness that may be suitable to the season when it is used.

Preparation of the hard varnish used by Callot, commonly called the Florence Varnish.—Take four ounces of fat oil, very clear, and made of good linseed oil, like that used by painters; heat it in a clean pot of glazed earthenware, and afterwards put to it four ounces of mastich well powdered, and stir the mixture briskly till the whole be well melted; then pass the whole mass through a piece of fine linen into a glass bottle with a long neck, that can be stopped very securely; and keep it for the use that will be below explained.

Method of applying the soft varnish to the plate, and of blackening it.—The plate being well polished and burnished, as also cleansed from all greasiness by chalk or Spanish white, fix a hand-vice on the edge of the plate where no work is intended to be, to serve as a handle for managing it when warm; then put it upon a chafing-dish, in which there is a moderate fire, and cover the whole plate equally with a thin coat of the varnish; and whilst the plate is warm, and the varnish upon it in a fluid state, beat every part of the varnish gently with a small ball or dauber made of cotton tied up in taffety; which operation smoothes and distributes the varnish equally over the plate.

When the plate is thus uniformly and thinly covered with the varnish, it must be blackened by a piece of flambeau, or of a large candle which affords a copious smoke; sometimes two or even four such candles are used together, for the sake of dispatch, that the varnish may not grow cold; which if it does during the operation, the plate must then be heated again, that it may be in a melted state when that operation is performed; but great care must be taken not to burn it, which, when it happens, may be easily perceived by the varnish appearing burnt and losing its gloss. The following expedient is made use of for the more commodiously blackening the varnish, and is particularly necessary where the plates are large: Fix a strong hook in the roof of the room, through which pass four pieces of cord of equal length, at the end of which are fixed four iron rings of about four inches in diameter, for supporting the corners of the plate. The plate, being thus suspended in the air, with the varnished side downwards, may be blackened with great convenience; but this is not, however, absolutely requisite, excepting in the case of large plates, which could not, without difficulty, be suspended, unless this or some other such contrivance were made use of.

It is proper to be very cautious in keeping the flambeau or candle at a due distance from the plate, lest the wick should touch the varnish, which would both sully and mark it. If it appear that the smoke has not penetrated the varnish, the plate must again be placed for some little time over the chafing-dish; and it will be found that, in proportion as the plate grows hot, the varnish will melt and incorporate with the black which lay above it, in such a manner that the whole will be equally pervaded by it.

Above all things, in this operation, the greatest caution should be used to keep the fire all the time moderate; and to move frequently the plate, and change the place of all the parts of it, that the varnish may be alike melted everywhere, and kept from burning. Care must also be taken, that during this time, and even till the varnish be entirely cold, no filth, sparks, or dust, fly on it; for they would then stick fast and spoil the work.

Method of applying the hard varnish.—This is precisely the same as that for the soft; it is spread equally over the warm plate with the taffety-ball, and smoked in the same manner; only, after it is smoked, it must be baked, or dried over a gentle fire of charcoal, till the smoke from the varnish begins to decrease; taking care not to overheat the plate, which would both soften it and burn the varnish.

The plate being thus prepared, and an exact drawing of the outlines of the design made upon thin paper, the other side of the paper must be well rubbed with chalk or Spanish whitening, or, which is better, with red chalk scraped to a powder: the loose chalk is then cleared off with a linen rag, and the stained side of the paper is laid upon the varnish, fixing the corners to the plate with wax or wafers, to prevent its shuffling; and with a blunted needle or pointer the drawing is slightly traced, and communicates to the varnish an exact outline of the design to be etched.

A variety of pointers is necessary for the work. Those used for the broad large strokes ought to be very blunt, exceedingly round, and well polished at the point; the sole of a shoe answers very well for polishing the points. The finest ought to be as sharp as a needle. If any scratches or false strokes happen in the working, they are to be stopped up with a hair pencil dipped in Venetian varnish mixed with lamp black, by which means these places will be defended from the action of the aquafortis.

The next operation is that of eating or corroding the plate with aquafortis, in order to which a border of soft wax, being a composition of bees-wax melted and tempered with a little Venice turpentine and tallow, must be fastened round the plate about an inch high, in the form of a little wall or rampart, to contain the aquafortis. At one of the corners of this border a gutter is usually made, which serves for commodiously pouring the aquafortis off the plate. The plate being thus bordered, take a due quantity of the refiner's aquafortis, mix it with half its quantity of common water, and pour it gently on, till it rise above a finger's breadth above the surface of the plate; then, if all things have been rightly conducted, it will soon be seen that the aquafortis exerts its action in the hatches which have been strongly touched; but those more weakly engraved will appear at first clear, and of the colour of the copper. The menstruum must therefore be suffered to continue on the plate till its effects become visible on the more tender parts; then the aquafortis should be poured off, the plate washed with clean water, and dried before the fire; after which take a small pencil dipped into the Venetian varnish, and cover with it the lighter parts of the plate. This being done, the aquafortis must again be poured on, and suffered to continue a longer or a shorter time, according to the strength of the menstruum or the nature of the engraving; after which it must be poured off as before, and the plate immediately washed with water.

It may not be improper to observe, that, when the aquafortis is on the plate, a feather should be used to cleanse away the foulness of the verdigris that gathers in the hatches when the aquafortis operates on them, and to give it more room to exert its action; for by moving the aquafortis to and fro on the plate by the feather, and brushing away the black saline matter where it appears to be formed, the hatches will be cleansed, and the aquafortis exert its whole force equally on every part.

The plate being thus sufficiently corroded by the aquafortis, and well washed with water, it must be warmed at the fire, and the border of wax removed; after which it must be made hotter till the varnish melt; then it must be well wiped with a linen cloth, and afterwards rubbed well with oil of olives, when it will be ready to be retouched and finished by the graver.

ETELENT, a town of the Arabian Irak, on the river Tigris, 66 miles north-north-west of Bassora.

ETEOCLES, in fabulous history, a son of Œdipus and Jocasta. After his father's death, it was agreed between him and his brother Polynices that they should both share the royalty, and reign a year each alternately. Eteocles by right of seniority first ascended the throne; but after the first year of his reign had expired, he refused to give up the crown to his brother, according to their mutual agreement. Resolved to punish such an open violation of a solemn engagement, Polynices went to implore the assistance of Adrastus, king of Argos, received that king's daughter in marriage, and was soon afterwards assisted with a strong army, headed by seven famous generals. Whilst these hostile preparations were making, Eteocles on his part did not remain inactive. He chose seven brave chiefs to oppose the seven leaders of the Argives, and stationed them at the seven gates of the city; he placed himself against his brother Polynices, and opposed Menalippus to Tydeus, Polyphontes to Capaneus, Megareus to Eteocles, Hyperbius to Parthenopæus, and Lasthenes to Amphiaraus. Much blood having been shed in light and unavailing skirmishes, it was at last agreed between the two brothers that the war should be decided by single combat. An encounter accordingly ensued, and was conducted with such inveterate fury that both combatants fell; nay it is even pretended that the ashes of these two brothers, who had been so inimical to each other while living, separated on the burning pile, as if sensible of resentment, and hostile to reconciliation.

ETERNITY, an attribute of God, expressing his infinite or endless duration.

Eternity, in *Mythology*, a divinity among the Romans, who had neither temples nor altars, but who was represented under the figure of a woman holding the sun in one hand and the moon in the other. The symbols of this divinity were a phœnix, a globe, and an elephant.

ETESIÆ, or Etesian Winds, are such as blow at stated times of the year, from what point soever of the compass they come. They are so called from the Greek word ετος, *year*, being yearly or anniversary winds, such as are now called monsoons and trade-winds, which in some parts of the world continue constantly blowing in the same direction during stated seasons of the year. Thus the north winds, which during the dog-days constantly blow upon the coasts of Egypt, and prevent all ships sailing out of Alexandria for that season, are called *etesiæ* in Cæsar's Commentaries; and in other authors, the west and east winds are called *etesiæ* when these continue blowing for certain seasons of the year.

Cellarius endeavours to prove that those winds are properly etesian which blow from that part of the horizon which is between the north and west about the time of the solstice. In ancient writers they are represented as of a very mild and gentle kind; and are called *somniculosi* and *delicati*, from their sleeping or ceasing to blow in the night.

ETFU, or Edfou, a town of Upper Egypt, celebrated on account of the sublime temple of Apollonopolis, which, Denon observes (*Trav.* ii. 277), is "the most beautiful of all Egypt, and, next to those of Thebes, the largest. Being built," he adds, "at a period when the arts and sciences had acquired all their splendour, the workmanship of every part is equally beautiful, the hieroglyphics are admirably executed, the figures more varied, and the architecture of a higher order, than in the Theban edifices, the building of which must be referred to an earlier age. See article Egypt.

ETHER, an extremely volatile fluid, produced by the distillation of alcohol with an acid. See Chemistry.

ETHERIDGE, or Etherege, Sir George, a wit and comic genius in the reigns of Charles II. and James II. was descended from an ancient family in Oxfordshire, and born in 1636. He travelled in his youth; and, not being able to confine himself to the study of the law, devoted himself to the acquisition of lighter and gayer accomplishments. His first dramatic performance, entitled *Comical Revenge, or Love in a Tub*, appeared in 1664, and introduced him to the leading wits of the time; in 1668 he produced a comedy called *She would if she could;* and in 1676 he published his last comedy, called the *Man of Mode, or Sir Fopling Flutter*, which is certainly an elegant comedy, and contains much of the real manners of high life. This piece he dedicated to the Duchess of York, in whose service he then was, and who entertained so great a regard for him, that when, on the accession of James II. she became queen, she procured his being sent as ambassador first to Hamburg and afterwards to Ratisbon, where he continued until his majesty had quitted the kingdom. Our author being addicted to certain gay extravagances, had greatly impaired his fortune, in order to repair which, he paid his addresses to a rich widow; but the lady being ambitious, had determined not to condescend to a marriage with any man who could not bestow upon her a title; and on this account he was obliged to purchase a knighthood. None of our writers has exactly fixed the period of Sir George's death, though all seem to place it not long after the Revolution. Some say that on this event he followed his master King James into France, and died there; but the authors of the *Biographia Britannica* mention a report that he came to an untimely death by an unlucky accident at Ratisbon. Having entertained some company at his house, where he had taken his glass rather too freely, and being, through his great complaisance, forward in waiting on his guests at their departure, he is said to have tumbled down stairs, broken his neck, and thus fallen a martyr to mirth and jollity. As to the literary character of Etheridge, he seems to have possessed a genius the vivacity of which required little cultivation; for we have no proofs of his having made any attainments in scholarship. His works, however, have not escaped censure on account of that licentiousness which pervades and renders them dangerous to young unsophisticated minds; and the more so on account of the lively wit with which it is as it were gilded or lackered. The only prose production of Etheridge is a short piece entitled *An Account of the Rejoycing at the Diet of Ratisbonne, performed by Sir George Etherege, Knight, residing there from his Majesty of Great Britain; upon occasion of the birth of the Prince of Wales. In a Letter from himself.* Printed at the Savoy, 1688.

ETHICS, the doctrine of manners, or the science of moral philosophy. The word is formed from ηθος, *mos*, ηθη, *mores*, manners; because it is the object of ethics to investigate the manners or conduct of man. See Moral Philosophy.

ETHIOPIA, a name which, as vaguely applied by the ancients, comprehended all Africa south of Egypt, and of the mountain range of Atlas, including Nubia and Abyssinia, but which is, in its more restricted and proper signification, applied to the country which was bounded on the north by Egypt, on the west by Libya Interior, on the east by the Red Sea, and on the south by a part of Africa unknown to the ancients. (See articles Abyssinia and Africa.) Although this vast tract of country must at different times have varied in extent, particularly on the side of Libya Interior, where it had no definite or ascertained boundary, yet it seems for many ages to have comprehended the kingdoms of Dongola, Sennaar, and Abyssinia, with part of Adel or Zeila, to have extended seventeen degrees in longitude, and to have reached from the tropic of Cancer to within six degrees of the equator.[1] In a still more limited sense, the term Ethiopia was applied to the island of Meroë, included between the main branch of the Nile and the Astaboras or Tacazze, the capital of which was also called Meroë; and it seems to have formed no part of the country which is now denominated Abyssinia. This region, which conquered Egypt, and which Cambyses, after having subdued that country, vainly sought to conquer, was long involved in mystery; and there is no record of its having ever been reached by any land expedition. Neither Petronius when sent by Augustus against Queen Candace, nor Probus in his expeditions against the Blemmyes, penetrated as far as Meroë; and, in fact, it is only in recent times that the dark cloud under which it was so long hid has been dispelled by the hardy enterprises of Burckhardt and Caillaud, particularly the latter. (See article Abyssinia, and Heeren's *Historical Researches.*) To Ethiopia proper the ancients gave various other names, an enumeration of which will be found in the seventh volume of the *Universal History*, part second, London, 1744, folio.

ETHIOPIAN NATIONS. A great many nations, different and distant from one another, were formerly comprehended under the denomination of Ethiopian. In ancient times the natural history of man was but little cultivated. Nations were distinguished according to the most obvious difference in their appearance, namely, their colour; and all who presented the most striking contrast to Europeans, either by a very dark or completely black skin, received the appellation of Ethiopians. Hence we find Ethiopian nations scattered over a considerable part of the ancient world; and although Africa certainly contained the greatest number of these, yet they were by no means confined to that continent alone. A considerable tract of Asia was occupied by an Ethiopian race; and as India was often made to comprehend southern Africa, so, in like manner, Ethiopia was made to include southern India. But it is of importance that the extent of these nations, and the various seats occupied by them, should be more accurately defined.

---

[1] *Universal History*, vol. vii. part 2d, p. 180. London, 1744, fol.

Anciently the native tribes of Africa were divided into two distinct classes; the Libyans and the Ethiopians. "Four nations," says Herodotus, "occupy Africa, and no more; two of which are aboriginal, and two not. The Libyans and Ethiopians are aboriginal, the former being situated northward, and the latter southward in Libya; the foreign settlers are Phœnicians and Greeks." This division was exactly followed by succeeding writers. Under the name of Libyans the father of history comprehended all the nations inhabiting northern Africa, exclusive of the Carthaginians and Greeks, the separate tribes which extended as far as the Lesser Syrtis, and the nomadic tribes of north-western Africa. But the question as to who these nations were, and whether any of their descendants may now be discovered, cannot be answered without difficulty, owing to the changes which the migratory invasions of the Arabs have produced in northern Africa. The narratives of modern travellers, however, have made us acquainted with two nations altogether different from the Arabs and negroes; we mean the Tibboos and the Tuaricks. They dwell to the south and west of Fezzan, their territory being bounded on the south-east by Bornou, on the south by Nigritia, and on the west by Fez and Morocco; they are divided into many tribes, all speaking the same language, which is different from the Arabic; their lineaments have nothing of the negro character or contour; and their colour, which seems to vary in tint according to their place of abode and mode of life, is of almost every shade and hue between white and black. The Tuaricks, in particular, are described as a very fine race of men; tall, straight, and handsome, with an air of independence. They are generally white, though in their complexion considerably tanned by the climate, and their arms and bodies are as fair as those of many Europeans. Their language is the Breber, or original African tongue; they inhabit the immense tract denominated the Sahara or Great Desert; they are of numerous tribes, some of whom wander like the Arabs; and they subsist chiefly by plunder. The Tuaricks travel on the maherri or dromedary, by means of which they perform long journeys in an incredibly short space of time; and many of their tribes are at perpetual war with the Soudan states, from which they carry off great numbers of slaves, the principal article of their trade. The nearest place of this people is about ten days' journey to the south of Mourzouk.

The Tibboos are in every respect a different people from the Tuaricks. Their colour is of the brightest black, but their profile has nothing of the negro character; they have aquiline noses, fine teeth, and lips formed like those of Europeans; in civilization they are below the Tuaricks, living partly in caves and partly in villages situated upon barren rocks or hills; and they follow the slave trade, but do not trade to Soudan. From a comparison of the Tuaricks and Tibboos, Heeren has been led to conjecture that the former spread from north to south, and the latter from south to north. But it is nearly as difficult to draw an accurate line of demarcation between these tribes and those of the negro race, as between the ancient Libyans and Ethiopians. It is no doubt true that the southern boundaries of the Great Desert may in general be taken as the limits of the negro countries; but, on the other hand, it is certain that separate black tribes, whether completely negro or not, have both in ancient and modern times penetrated a considerable way into the Sahara or Great Desert. From Lyon's map we learn that at present the black population commences about the twenty-eighth degree of north latitude. The circumstance mentioned by Herodotus, of the Ethiopians having been hunted by the Garamantes in four-horse chariots, and the detached tribes of this people which dwelt along the Atlantic coast almost as far as Cerne, show that this was also the case in early times; and from the narratives of modern travellers we collect that, in the Tibesti Mountains, the same territory where the Garamantes hunted the Ethiopians, black tribes are still to be found. If, then, the numerous interminglings of these tribes which must necessarily have taken place in a long course of ages, and the circumstances which, in a country like Africa, are continually occurring to produce changes and migrations, together with the ordinary operation of physical laws, be all duly considered, the difficulty, if not the impossibility, of drawing an accurate boundary line between the Libyans and Ethiopians, will easily be perceived.

So much for the western nations of northern Africa. With regard to the eastern, the inhabitants of the banks of the Nile above Egypt, and of the adjacent countries as far as the Arabian Gulf; as their country in general is comprehended under the name of Ethiopia, the denomination has been transferred to its inhabitants, who have received the name of Ethiopians, not by reason of their descent, but simply because their complexion happens to be dark. Herodotus classes the Ethiopians according to the growth of their hair, and particularly distinguishes the negroes from the other swarthy tribes. "The Asiatic Ethiopians," says he, "have straight hair; whilst the African Ethiopians have the most curly hair of all men." But, as we have already seen, he is mistaken in speaking thus of all the black tribes of Africa, some of whom are not negroes, and, notwithstanding the black hue of their skins, have straight hair. He judged according to what he saw of them in Upper Egypt, the most southern point of his travels; but, from not having penetrated farther into the interior of the African continent, he judged erroneously. We are, however, indebted to him for one important piece of information, namely, that the eastern districts of northern Africa, presently comprehended under the names of Nubia and Sennaar, were then occupied by two distinct races; one aboriginal, which he includes under the general appellation of Ethiopians; and the other immigratory, of Arabian origin, and leading for the most part a wandering life. That such was actually the case during the Persian period, and even as far back as the times of the Pharaohs, there are many proofs; and we shall soon see how the statement in question tallies with the accounts of recent travellers. But still it would be as difficult to draw a precise line of distinction between the Arabian and aboriginal nations here, as between the negroes and Berbers in western Africa; more especially as many of the immigratory tribes have intermingled with the elder stock, and as the latter lay claim to an Arabian descent, which they have been led to consider as the more honourable. Language, however, if due caution be used in examining it, forms the most certain test, and indeed may be considered as decisive on this point. For as it is improbable that the Arabians, who pride themselves on their language, would ever relinquish it in order to adopt that of a barbarous or conquered people; so, on the other hand, all those nations who do not speak Arabic may be ranked as aboriginal, whatever descent their traditions may claim for them; and hence all of them may be included under the general appellation of Berbers or Barabras, a name which, in the same sense, is still applied to them in Egypt, if not in other countries.

Amongst these nations the first place is due to the Nubians, who live in a land of monuments, perhaps erected by their forefathers, and who, on that account, have greater claims on our attention. This name does not occur until the age of the Ptolemies, and is first mentioned by Eratosthenes; but it soon came into use as the general denomination of all the tribes living on both sides of the Nile from Egypt to Sennaar, and the ancient Meroë, and sometimes, in a more limited sense, as applicable only to the inhabitants of the present Dongola. The Nubians are distinguished by this, that their dwellings are in the valley of the Nile, amidst numerous monuments of ancient splendour and civilization. They speak a language entirely different from the Arabic; they are of a dark-brown colour, with hair either naturally curly or artificially arranged, but not at all woolly, and often formed into an elevated ornament, as in the figures on the monuments; and their visage has nothing whatever of the negro physiognomy. The men are well formed, strong, and muscular, with fine countenances, but are something shorter in stature than the Egyptians; they have only a little beard growing under the chin, as in the Egyptian statues; they are thinly clad, indeed almost naked; and they are all armed with a spear, a dagger, and a large shield formed of the hide of the hippopotamus. The women are well made, with very pleasing features; and, as they are usually bought of their parents, they frequently intermarry with the Arabs. But the distinctive characteristics of race have not thereby been destroyed. The Nubian has more courage and daring than the Arab; and his beauty is as unchangeable as that of a statue in a rock temple. At Dongola the language chiefly in use is the Nubian, the Arabian being but imperfectly understood. To the south of Dongola is the country of the Scheygias, a remarkable race of a very dark-brown or rather black complexion, but not negroes. Until recently this people enjoyed complete independence, and defended their liberty against the army of the viceroy of Egypt, under his son Ismael Pasha, with heroic courage; but being overpowered by numbers and discipline, they were almost extirpated. The Scheygias speak the Arabic, and are probably of mixed origin. They are divided into three classes or castes; that of the learned, who have books and schools; that of the warriors, who are horsemen, each armed with a double-pointed spear, a sword, and a shield; and that of the merchants, who carry on a considerable traffic in exchanging native products for such foreign articles as they require. In their country, which borders upon that of the Berbers, are first met with the pyramidal monuments which adorned the ancient Meroë; the name of which has still been preserved in that of their chief place *Merawé*, though the ancient capital so called must be sought for farther to the south. With regard to the Berbers, they call themselves Arabians, that they may not be confounded with the negroes; but, from Burckhardt's description, there can be little doubt that they belong to the Nubian race.[1]

Above these regions, beyond the Astaboras or Tacazze, especially in Shendy, and thence along the Nile to Sennaar, the Arabic prevails; and the mass of the inhabitants may therefore be regarded as of Arabian descent, though with an intermixture of other blood. These places have always been, and still are, great resorts of trade; and this trade has ever been principally in the hands of Arabians, whose language, accordingly, extends as far as the confines of Abyssinia, where the Amhara and other dialects first begin to be spoken. But the Arabic is much less general among the scattered races wandering between the valley of the Nile and the Arabian Gulf; that is, among the Blemmyes, the Megabari, the Troglodytæ, and the Ichthyophagi, the tribes noticed by the ancient writers as occupying or roving through these parts. The principal race, however, is that to which Bruce and Niebuhr have given the name of Bischarries, the same who are called Bejas or Bedjas by the early writers. That this tribe is the same as the ancient Blemmyes has been very satisfactorily demonstrated by M. Quatremère. They occupy the same territory; their habits have in no respect changed; they are an aboriginal people, with nothing of the Arab about them; and consequently they belong to the class of nations comprehended under the general name of Berbers. The seat of the Bischarries begins in the north, where that of the Ababdés, extending from Cosseir to about the 23d degree of north latitude, terminates, and is principally a mountain ridge, which, rising close to the territory of the Ababdés, runs along the eastern coast of Africa to the neighbourhood of Suakin. This chain has from the earliest times been the abode of tribes who dwell in holes and caves originally formed by nature, but fashioned and improved by the inhabitants themselves, who have therefore been comprehended under the name of Troglodytes, or dwellers in caves. The Troglodytes of Ethiopia, according to Agatharcides, were herdsmen, with separate chiefs, or heads of tribes, amongst whom there existed a community of women, the result probably of their manner of life. During the rainy season they retired with their herds into the caves, where they lived upon clotted milk and blood; but as soon as the weather became favourable, they hastened with their cattle into the valleys, which afforded them pasturage, and which were often a subject of violent contention. Burckhardt gives nearly a similar description of these mountaineers, whom he represents as a very savage people, living entirely upon flesh and milk, and eating much of the former raw.[2] Some of these tribes spread themselves over the plains of Atbara, between the lower Tacazze and the mountains; but the peculiarities of the climate, particularly the overflowing of this branch of the Nile, which inundates the neighbouring plains, compels them to undertake a yearly migration in search of fresh pasturage. Another cause of their migrations, mentioned by Bruce, is the insect described by him under the name of the gadfly, which, from the commencement of the rainy season, abounds on the rich lands adjoining the Astaboras, and kills the cattle, if they are not immediately driven off to the higher sandy regions, whither the destructive insect does not follow them.

The southern part of the territory of Taka or Atbara, which is covered with thick forests, and overrun with savage beasts, as lions, panthers, elephants, and rhinoceroses, forms the seat of the hunting tribes, of whom a very accurate description has been given by Agatharcides. They dwell on the banks of the Astaboras, which separates them from Meroë; in other words, they are the Shangallas of Bruce. But no modern traveller has yet visited the interior of the district inhabited by this people. Bruce journeyed along its southern, and Burckhardt along its north-

---

[1] "The people of Berber," says he, "are a very handsome race. The native colour seems to be dark-red brown. Their features are not at all those of the negro, the face being oval, the nose often perfectly Grecian; the upper lip, however, is generally somewhat thicker than is considered beautiful, though it is still far from the negro lip. They are tall and thin, even more so than the Egyptians, and very healthy, sick persons being scarcely ever found among them." (*Travels in Nubia*, p. 216, 233.)

[2] "The Bischarries, who rarely descend from their mountains, are a very savage people. Their only cattle are camels and sheep, and they live entirely upon flesh and milk, eating much of the former raw. According to the relation of several Nubians, they are very fond of the hot blood of slaughtered sheep; but their great luxury is said to be the raw marrow of camels. Their language is different from the Arabic, and approaches the Abyssinian. They are divided into four tribes, which are often at war with one another for the possession of the pasturages. Their women are handsomely formed, with very fine eyes and teeth, and are of a frank disposition. They are a genuine aboriginal people of Africa."

Ethiopian Nations.

ern boundaries, in his route through Taka to Suakin: its forests, its wild beasts, and its still wilder inhabitants, render it inaccessible. The habits of these tribes have remained the same for two thousand years; they are still the same rude savages described by Agatharcides. The Hylophagæ dwell under the branches of trees, which they fix in the earth in order to make themselves tents; the Dobenatis, the most powerful race of the Shangallas, live upon elephants and rhinoceroses, the flesh of which they preserve by drying it in the sun; the Baasa subsist upon the flesh of lions, and even that of snakes, which are found of an enormous size; and farther to the south is a tribe who, during the summer, feed on locusts, which they preserve by first roasting and then drying them. In the extreme east dwell the Struthiophagi, or ostrich-eaters, who must inhabit plains where alone ostriches are to be found. Lastly, we have here a new proof of the great influence which the natural circumstances of country and climate exercise upon the destiny of the human race. The various tribes of Shangallas still remain hunters, and completely savage, because their soil is unfit either for agriculture or pasturage; whilst the Bischarries follow a pastoral life, because their mountains afford food for flocks and herds. Where nature compels men to follow a nomadic life, it is vain to expect even an approach towards civilization.

But there yet remains to be noticed an Ethiopian nation, highly celebrated in antiquity, and copiously described by Herodotus; we mean the Macrobians. For the place which they have obtained in history this people are indebted to the expedition which Cambyses, from motives of cupidity, directed against them. A rumour of the vast quantity of gold possessed by them determined the Persian conqueror of Egypt to undertake this expedition; but before engaging in the enterprise, he sent from the city of Elephantis in Upper Egypt some Ichthyophagi, who understood their language, as spies into their country, and furnished the latter with presents for the king of the Macrobians, consisting of a purple robe, a golden necklace, bracelets, perfumes, and a cask of palm wine. The report of the spies, whose real vocation did not escape the penetration of this people, was, upon the whole, favourable. The Macrobians were, according to them, a tall and handsome race of men, who had their own laws and institutions, and elected the tallest amongst them as their king. They were not unacquainted with the use of wine; their food consisted of boiled flesh and milk; and, according to the account of their king, they were remarkable for longevity. Their country abounded in gold, which was the metal in common use among them, even for the fetters of their prisoners; their sepulchres were made of glass (ὕαλος); and their dead, after being embowelled, as in Egypt, were covered over with plaster, and then placed in cases, upon which were painted portraits of the deceased. Lastly, in return for the presents of Cambyses, the prince of the Macrobians sent him a bow, desiring the envoys at the same time to inform their master, that when he could bend it as easily as a Persian bow, he might undertake his projected expedition. These particulars are curious, as showing that the Macrobians must have been a nation living under fixed laws and institutions; that they understood the working in metals; that they inhabited the richest gold country of Africa; that their usages were in some respects akin to those of the Egyptians; and that they had made some progress in the cultivation of at least one of the fine arts. It appears, however, that they were ignorant of agriculture, as they knew nothing of bread except by report. But our rules of judging will not always apply to the African nations, who, proceeding from different points, and advancing in different directions, must necessarily arrive at a different end from that attained by Europeans.

Much diversity of opinion has prevailed as to the part of Africa which was occupied by this people. Bruce supposes the Macrobians to have been a tribe of Shangallas, who dwelt in the lower parts of the gold countries, Cuba and Nuba, on both sides of the Nile, to the north of Fazukla; an opinion which he founds on the slight circumstance that this race are in the habit, by means of ferules of hides, of rendering their bows nearly inflexible, like that sent in defiance to Cambyses. But as none of the Shangalla tribes have attained that degree of civilization attributed to the Macrobians, Heeren thinks that their abode must be sought for in another and more southern region; and that, in fact, it can only be determined by the statement of Herodotus that it lay on the Indian Sea, and abounded in gold, which it either produced or imported. We are thus carried to some seaport beyond the Arabian Gulf, although we may not be able to say with certainty which; but a district is nevertheless spoken of where agriculture was not in use, and its inhabitants lived, not on bread, but on flesh; and this, Heeren, proceeding on the account given by Cosmas, surnamed the Indian, of a remarkable trade carried on with the rich gold country on the confines of the land of frankincense, conceives, on very probable grounds, to have been situated on some part of the coast between Babelmandel and Guardefui. The land of African frankincense, according to Bruce, begins at Babelmandel, and stretches eastward almost to Cape Guardefui, taking in part of Adel or Zeyla. But as the land of frankincense adjoined Sasu, which is mentioned by Cosmas as a country very rich in gold mines, and as Sasu was situated near the sea, it may be concluded that the latter formed part of the coast, and also comprehended one or more ports at which the trade was carried on. The distance of Axum[1] from the land of frankincense, stated by Cosmas at fifty days' journey, agrees very well with this conjecture, which, moreover, is confirmed by the accounts modern travellers have given of that part of the African coast stretching from Babelmandel to Guardefui, and which is inhabited by a race neither completely negroes nor Arabians. The Samaulies, who are the people here alluded to, are not savages, but a friendly, well-disposed race, engaged in commerce, which they carry on between Africa and Arabia. Gums, myrrh, and frankincense, cattle and slaves, are the commodities exported by them, in exchange for which, as well as for gold and ivory, they receive the productions of Arabia and India, particularly the latter. The profits of this trade are very great; and the commerce, if it were not checked by the exorbitant customs imposed by the native rulers, would be immense. Taking the narration of Cosmas, therefore, in conjunction with the circumstances stated by Herodotus, it does seem probable that the Macrobians of the latter should be sought for in this region, that is, on some part of the coast not far from Cape Guardefui; and if the particulars mentioned by the former be applied to the same people, then every material difficulty vanishes, and the whole appears in a natural and satisfactory light.[2]

The Ichthyophagi derive their name from their food, which consisted of fish; and, besides the tribes in Africa, some also on the coasts of Persia and Arabia received the same appellation for the same reason. The African Ichthyophagi belong properly to the Troglodytæ, or dwellers in caves, and are only distinguished from others of this class by their food and manner of life. It is a remark which the whole history of the human race confirms, that the nations or tribes which subsist on fish are the very lowest in the scale of civilization; and the wretched savages we have mentioned form no exception to the truth of the observation. Strangers to all domestic ties; with no dwellings excepting clefts and holes; and without even fishing implements, as they fed only on those fish which were left behind by the retiring floods, they seem to have been of all savages at once the most miserable and the most degraded. Such being their character and condition, it seems difficult to conceive how Cambyses came to choose from such a race, individuals to act as envoys or spies. But as he sent for the Ichthyophagi from Elephantis in Upper Egypt, where a party of them must consequently have lived, and as his choice was no doubt determined by their acquaintance with the country and language of the Ethiopians, it is probable that they belonged to the roving tribes, who carried on the trade between Egypt and Ethiopia, and formed the caravans which travelled from the one country to the other. There was in fact no other way of passing from Egypt to the country of the Macrobians but by a caravan; and these people, as they understood the language spoken in the latter, must have journeyed thither once or oftener. Heeren intimates a conjecture that they belonged to the Ababdés, whose country stretches to the neighbourhood of the region above described, and who, from the most remote times, have been carriers of merchandize.[1]

---

[1] The capital of Ethiopia.

[2] See Lord Valentia's *Travels*, vol. ii. p. 370–378. The vast quantity of gold is easily accounted for; it was either a natural product of the country, or the inhabitants had accumulated it by commerce; and hence the presents of the Persian king, consisting partly of golden ornaments, seemed to this people a mockery, which their prince was justified in taking as an insult, and returning by defiance.

The Ethiopian nations with which we have thus become acquainted must obviously be ranked, as a whole, in the lowest grade of civilization. Yet there still exists an evident difference of improvement among them; in fact, various gradations are observable, from the complete savage, whose rank might be disputed by the ourang-outang, to the hunting and fishing tribes, and from these again to the nomadic herdsmen of the mountains and the plains. But we do not anywhere discover a single nation which had united in a settled abode, and formed itself into a great and well-organized state. The nature of the country, and the climate, seem to have opposed a barrier which, in modern times at least, has not been overcome. Anciently, however, there did exist a better cultivated, and to a certain degree civilized Ethiopian people, who dwelt in cities, erected temples and other edifices, which they inscribed with hieroglyphics, lived under government and laws, and were famed over a considerable part of the earth for their progress in knowledge and the social arts. That state was Meroë.

Celebrated for upwards of two thousand years, Meroë, from its distant situation, has, until of late years, been involved in mystery and obscurity. But the hardy enterprises of Burckhardt and Caillaud, particularly the latter, have at length dispelled the dark cloud under which it was so long hidden; Meroë has at length been disclosed; and a new world of antiquities, the existence of which had not even been imagined, has been laid open, as it were, to our view. The southern boundary of Egypt had hitherto been considered as the utmost verge of ancient civilization and science. But more distant regions have at length been explored. Bruce and his predecessors led the way by crossing the Nubian desert, and others soon followed, who, penetrating the upper countries situated on the Nile, discovered that succession of monuments on its banks which has excited so much astonishment amongst antiquaries, as well by their number as their magnitude. Temple after temple appeared, some erected upon and others excavated in the rocks and the earth; scarcely was one passed when another appeared in view; colossal figures, buried up to their shoulders in sand, projected their enormous proportions; and an immense number of pyramids, with temples and ruins of cities close by or intermingled with them, rose to the sight of the astonished beholders. At last appeared the distant Meroë itself, with the ancient temple of Ammon still erect and majestic in its ruins.

The course of the Nile above Egypt, before its conflux with the Astaboras, lies through a valley enclosed on both sides by chains of hills, which sometimes recede and sometimes advance, until they almost approach the banks of the river. Any great deviation in the course of the stream is thus rendered impossible, though nothing exists to obstruct lesser windings in the wider portions of the enclosed valley. But as the soil of this valley was undoubtedly at one time as fertile in the upper regions as it is in Egypt itself (for where it could remain in that state it is still found so), we may conclude that it was at one time a highly cultivated country, with a numerous population, and a long succession of cities. As the mountain chains which enclose the valley are, however, succeeded on both sides of the river by sandy deserts,—on the east by the Nubian, and on the west by the great sandy waste which stretches right across Africa,—the sand has proved a still more formidable enemy here than in Egypt; and the lower chain affording but a slight defence, this deadly foe of all civilization has not only penetrated into the valley, but frequently buried, in part or in whole, the monuments which abound in it. The same cause must have occasioned some alterations in the course of the river itself, forcing separate branches into one channel, and joining small islands to the mainland. At all events, the valley of the Nile was certainly very different from what it is now, traces of old canals formed for extending its periodical overflow being everywhere visible; and these changes alone would have been sufficient to affect the condition of the inhabitants, even if other events had not conspired to accelerate the progress of decay. The river, deviating from its generally straight course, forms a bend or bow from 19° to 23° by running into the west, deeper into Libya; and the inner part of this incurvation is occupied by the Nubian desert. But the stream soon winds again to the eastward, and resumes a northerly direction, which it preserves throughout Nubia and Egypt.

For the first accounts of the course of the Nile above Egypt we are indebted to Herodotus, who collected them in Egypt, probably at Thebes or at Elephantis, beyond which he never proceeded. According to the information which he received, he states that, beyond the Egyptian boundary, the country becomes higher; that in this part a boat is dragged up the stream by means of a rope, fastened on either side, and if it chance to break, the boat is forced back by the violence of the current; that this navigation continues four days, the Nile winding, like the Meander, through a space of twelve schœni or seventy-two geographical miles; that the traveller next arrives at a plain where the Nile flows round an island named Tachompso; that the parts above Elephantis are inhabited by Ethiopians, excepting one half of the island, which is held by Egyptians; that close to the island is a vast lake,

Ethiopian Nations.

after crossing which the stream of the Nile, lost for a time in this expanse of water, is again met with; that a journey of forty days is then performed on the bank of the river; that in this part of the Nile sharp rocks rise above the water, and numerous shoals are met with, amongst which it is impossible to navigate; and that having passed through this country, the traveller again embarks in another boat, and, after twelve days' navigation, reaches an extensive city, the name of which is Meroë. Such is the statement of Herodotus, founded upon the information which he had collected in Egypt. In comparing it with the accounts of recent travellers, we shall find that all those objects, such as cliffs and rocks, which are not liable to change, still answer to his description; whilst, in other respects, supposing Herodotus to have been correctly informed, material alterations appear to have taken place.

Amongst the moderns, Norden was the first who attempted to navigate the Nile above Egypt, and to draw maps of its course. These, which reach only to Derri, Derar, or Deir, the end of his journey, are, notwithstanding all that has since been done, still the fullest in particulars. Burckhardt, in his first journey, kept near the banks of the river, and only penetrated as far as the frontiers of Dongola; in his second he traversed the Nubian desert. The journey and map of Legh extend no farther than the second cataract; and the magnificent work of Gau only reaches to the same place. The statements of Senkowsky, up to this limit, are also exceedingly accurate. Above the second cataract, from Wady-Halfa to the boundaries of Sennaar, or the ancient Meroë, Waddington and Hanbury have given a map of the course of the Nile; and for the more distant regions the authorities are Bruce, Burckhardt, and particularly Caillaud.

The winding course of the Nile above Syene is shown in Norden's twenty-fourth chart. The river here holds a serpentine course, but without any considerable curvature. Its current is so strong that Norden was obliged to quit his bark; Legh also found it difficult to make head against the stream; and, in the territory of Kalabsché, where it is confined within a channel about thirty yards in width, its impetuosity becomes so great as to render navigation exceedingly hazardous. As the voyage to the island of Tachompso is stated by Herodotus to be twelve schœni, or seventy-two geographical miles, which, navigating against the stream, it required four days to perform, this island may therefore be that now called Kalabsché, or another, named Ghyrshé, about twenty miles farther. The river contains many islands of which an accurate account is still wanting; but the great difficulty is the lake through which it is said to have flowed. The river, it is true, spreads out sometimes to a greater and sometimes to a less extent, but a lake is nowhere to be found. It follows, therefore, either that Herodotus was misinformed in regard to this particular, or that the features of the region in question have undergone a change, whether from the accumulation of sand, or from the gradual detrition of a natural barrier, which had originally dammed up the stream to a certain height, and formed the lake mentioned by him. We incline to the latter opinion, which is strengthened by what is known to have taken place at the cataracts; for, owing to the diminished obstruction, these rapids no longer answer the description of them given by the ancients. It may also be added, that, at the time of the annual floods, the Nile, in those parts where the mountain chains recede and suffer its waters to cover the valley, presents the appearance of a lake. From the site of the supposed lake the navigation of the stream continues unobstructed as far as the second cataract, near Wady-Halfa (21° 50′), a view of which is given by Gau; but above this cataract the bed of the river is often interrupted by rocky shoals, which cause rapids. Of these, one is near Wady-Attyr, another near Wady-Ambigo, and a third near Wady-Lamulé (under 21°); beyond which Burckhardt met with two others, the farthest being on the northern boundary of the kingdom of Dongola (19° 30′). But the obstruction of the navigation does not stop here; for Caillaud continues it as far as Merawé, where the great falls commence. Above the northern boundary of Dongola, the features of the country become much changed; the mountain chains recede much farther; and the Nile, hitherto frequently compressed into a narrow channel, here spreads out into many branches, enclosing a number of fruitful islands adorned with palm-groves, vineyards, and meadows covered with numerous herds, especially of camels. Every thing, says Hanbury, might here be found in abundance; nature has done her part, if man had performed his. But at this time the country appeared to great disadvantage, owing to the wanton devastation committed by the Egyptian army under Ismael Pasha. Having thus reached the immediate vicinity of the junction of the Astaboras or Tacazze with the Nile, or, in other words, the ancient island of Meroë, we shall, before entering the latter, pause for a little, to contemplate the monuments scattered along the Nubian portion of the valley of the Nile, the external features of which we have just described.

That the Nubian valley was once covered, on both sides of the river, with towns or villages, containing a numerous population, cannot possibly be doubted. Of these, Pliny has left us the names, and only the names, of twenty on each side. In his time they no longer existed, and it is probable that they were destroyed in the earlier contests between Egypt and Ethiopia. They must therefore have been very ancient; indeed the great population of the upper valley of the Nile favours the opinion which refers these towns to the time of the Pharaohs. But in Nubia, as in Egypt, the great works in architecture were confined to public edifices. The people during the day lived almost in the open air, and their dwellings were little more than resting-places for the night, or mere huts, which fell into decay as soon as they ceased to be occupied, and were speedily swept from the earth. Yet the ancient Parembole is still found in the present Debod; the name of Taphis is preserved in that of Tafa; Kalabsché is manifestly the ancient Talmis; Pselas is the present Dakké; Metacompso nominally survives in the modern Kobban; farther south Abrim represents the ancient Primis; and all these places are below the first Nubian cataract. But though the dwellings of man have vanished, not so those of the gods: the habitations of the former, like himself, have passed away; those of the latter seem to be imperishable. The series of temples commences on both sides of the Nile, almost immediately above the Egyptian cataracts. The first is that of Debod, twelve miles beyond Philæ (see article Egypt), on the left bank of the Nile; at nearly the same distance is that of Kardassy; and only five miles farther, that of Tafa. Next come the two temples of Kalabsché, one built upon the ground, the other hewn in the rocks; at about ten miles more is the temple of Dandour; and again, at a like distance, that of Ghyrshé, partly above ground, partly hewn out of a rock. Ten miles farther up is the temple of Dakké, at the same distance that of Maharraka, and sixteen miles farther that of Seboa, half built above, and half cut into the earth. Thirty miles farther stands the temple of Derar, on the right side; and sixty miles beyond this is the temple in the rocks of Ipsambul, with its colossi, forty-eight miles below the Nubian cataract of Wady-Halfa, near to which stands another temple. Beyond this the chain is broken, and does not recommence till about a hundred and fifty miles farther up, below the island of Sai, where there is a large temple; and thirty miles onward appears the temple of Soleb, which Burckhardt considers as the most southern of those constructed in the Egyptian style. Here, in fact, the first chain obviously terminates; but a new one also commences on the frontiers of the ancient Meroë; and about two hundred miles farther, near Merawé and the adjoining mountain of Berkal, temples re-appear, accompanied with groups of pyramids. About two hundred and forty miles onward we reach the junction of the Nile and Astaboras, crossing which we enter the island of Meroë, and, proceeding about ninety miles farther, arrive at the temples and pyramidal ruins of the ancient city of Meroë.

It would be inconsistent with the object of this article to attempt any general description of the monuments which we have just enumerated; this may be introduced with greater propriety under another head. But an attentive examination of these monuments suggests some general observations both as to their character and the history of the country where they are found, which we shall endeavour to state as briefly as possible. And, *first*, it appears that the religion, rites, and arts of Egypt, were not confined to its proper territory, but extended to the upper valley of the Nile, where the same deities were worshipped, and the rites of Ammon everywhere predominated, together with those of his temple-kindred and companions. *Secondly*, the character of the architecture, between which and the ornaments it received from the hand of the sculptor a distinction must be made, is upon the whole the same; but there is a progress in it which cannot be mistaken. In the monuments of Egypt, the art is found in its greatest perfection, perhaps also in its decline; here, however, we observe it in its rise and progress, from small grottos, such as those of Derar, until it attained the sublime magnitude in which it exists at Ipsambul. *Thirdly*, as the science of architecture appears to have commenced with grottos and tombs, and to have been perfected by degrees, the rock-monuments probably determined its principal character to the colossal form which it assumed. From the grottos it first rose into the open air; and then quitting this junction, erected monuments unconnected with such excavations. *Fourthly*, in regard to the sculptures and bas-reliefs with which the walls and columns of these monuments, below ground as well as above, are profusely ornamented, it would seem that, in general, they are not coeval with the edifices on which they are found. In the architecture, and even in the colossal statues, a progress may be traced from the first rude attempts to a state of comparative perfection: but in the reliefs nothing of the kind is discernible; all of these exhibit, in nearly an equal degree, the most improved state of the art; and the subject-matter of the inscriptions shows that the decoration of the walls and columns was posterior in date to the erection of the monuments. On every part of the temples of Ipsambul, Kalabsché, Derar, Ghyrshé, and Seboa, may be read in hieroglyphics the name of Rhamses the Great, or Sesostris, one of whose first military undertakings was an expedition against Ethiopia. *Fifthly*, the conclusion of Heeren, that these pictorial representations are not to be considered as mere ornaments or fanciful creations of art, but as historical records, is supported by every thing that has yet been discovered on the subject. And, *lastly*, as it appears that the Nubian monuments, strictly so called, are more ancient than those of Egypt, and that the course of improvement has, in general, followed that of the stream, it is highly probable that the latter country, whatever ascendency it may have acquired when its people had become a powerful nation, originally derived from the upper valley of the Nile the elements both of art and civilization.

But where, it may be asked, is the renowned Meroë to be found? This is the question which now demands our attention; and, without entering into the details of the inquiry, we shall state the results which Heeren has deduced from the statements of ancient writers, compared with and corrected by the accounts of modern travellers. The island of Meroë, then, is the present province of Atbar, situated between the river of the same name, otherwise called the Tacazze, on the right, and the Bahr-el-Abiad and Nile on the left. The point where the island commences is at the junction of the Tacazze and Nile; it is enclosed on the south by a branch of the above-mentioned river, the Waldubba, and a branch of the Nile, called the Bahad, the sources of which are nearly in the same district; it is situated between 13° and 18° of north latitude; and in recent times it has formed part of the kingdom of Sennaar, whilst the southern portion belongs to Abyssinia. Meroë was therefore an extensive district, surrounded by rivers, and in superficial content exceeded that of Sicily by rather more than one half. In the strict sense of the term it cannot be called an island, because it is not completely enclosed by rivers; but it was taken for such because the various rivers which flow round it were all considered as branches of the Nile; and, moreover, in the rainy season, it becomes a complete island by the overflowing of the rivers. Upon this island stood the ancient city of the same name, a little below the present Shendy, under 17° north latitude, and 5° 30′ east longitude. Its situation has been determined with the nicest accuracy; and its ruins, which Bruce and Burckhardt only saw at a distance, and hastily, confirm the deduction made from the testimony of the ancients. These, which have been carefully examined by later travellers, and placed before our eyes by their drawings, are very extensive, not being confined to a single spot, but found in a number of places; indeed the whole strip of land from Shendy to Gherri teems with them, and may therefore be considered as classic ground. The monuments still remaining consist of temples and pyramids, all private dwellings having long ago been destroyed. To the east of Assur is what Heeren denominates the great churchyard of pyramids, about eighty in number. They are divided into three groups, of which the most northern includes the largest and best preserved. They appear small compared with those of Middle Egypt, but they are more wonderful on account of their number. They are built of granite, but do not seem so massive in the interior as the Egyptian pyramids. It has not been ascertained whether sarcophagi and mummies are to be found within these monuments, or whether they are to be regarded as exclusively sepulchral structures. The antiquities to the south of Shendy consist of temples, in which Meroë itself was not deficient; two, a larger and a smaller one, being laid down in the plan of Caillaud. In these monuments, as well as in those of Naga or Naka, to the south-east of Shendy, we discover the architecture which attained to such perfection in the great temples of Egypt; and also observe the worship of Ammon and his kindred or associate gods, differing in no material respect from that which is exhibited on the monuments of Upper Egypt. At the distance of two days' journey from the pyramids, in the neighbourhood of which stood the city of Meroë, is the Ammonium, or ancient temple of Jupiter Ammon, within whose labyrinthine passages and courts was contained the oracle of the king of the gods. This has been clearly and fully established by Heeren, from the information furnished by Caillaud, compared with the statements of the ancient writers. The rarity of sculpture and hieroglyphics on this monument is remarkable; no trace of Egyptian art has been discovered here; and the few figures on the pillars have nothing in common with it,

Ethiopian Nations.

though one of them has evidently the hair dressed in the broad Nubian fashion. Thus, then, has at length been ascertained beyond all doubt that remarkable spot which antiquity generally regarded as the cradle of the arts and sciences; where hieroglyphical writing was first discovered; and where temples and pyramids had been constructed, whilst Egypt still remained ignorant of their existence, and the land afterwards called that of the Pharaohs was unadorned with monuments. For a masterly account of the religion, government, and laws of Meroë, as well as illustrations of its history, the reader is referred to the *Researches* of Heeren, which we have here followed.

Meroë was the capital of a country which both the Hebrew and Greek writers describe as one of the richest upon earth, and which, besides being reputed the cradle of the arts and sciences, was, from the most remote ages, distinguished for its trade and commerce. The Phœnicians, and even the Jews, were acquainted with it; the Hebrew poets cite the names of its various cities and harbours, expatiating on the treasures which were imported from them; and no sooner had the Greeks obtained some knowledge of these regions, than they exhausted language in extolling their boundless riches. From the very earliest times a close connection appears to have subsisted between Egypt and Ethiopia. The Hebrew poets seldom mention the one without the other, and both are represented as commercial nations. When Isaiah celebrates the victories of Cyrus, their submission is spoken of as his most magnificent reward: "The trade of the Egyptians, and the merchandise of the Ethiopians, and of the tall men of Saba, will come over to thee and become thine own." When Jeremiah extols the great victory which Nebuchadnezzar obtained over Pharaoh-Necho near Carchemish, the Ethiopians are mentioned as allied to the Egyptians; and when Ezekiel threatens the downfal of Egypt, he unites it with the most distant Ethiopia. Every page of Egyptian history, indeed, exhibits proofs of the close intimacy which subsisted between these countries; and commerce appears to have formed the common tie which united them. Of this commerce Heeren has collected all the particulars which are to be gleaned from the ancient writers, sacred and profane, and illustrated their statements with his usual ability and erudition. The conclusions which he has deduced from his investigations are alike curious and important, and, resting upon grounds which cannot be shaken, may be received as demonstrated propositions. *First*, it appears that, in the earlier ages, a commercial intercourse existed between the countries of southern Asia and Africa, between India and Arabia, Ethiopia, Libya, and Egypt, which intercourse was founded upon their mutual necessities, and became the means by which the civilization of these people was promoted. *Secondly*, the principal seat of this national intercourse for Africa was Meroë; and its principal route is still pointed out by a chain of ruins, extending from the shores of the Indian Sea to the Mediterranean. Adule, Azab, and Axum, are links of this chain between Arabia Felix or Yemen, and Meroë; Thebes and Ammonium are those between Meroë, Egypt, and Carthage. *Thirdly*, the chief places of this trade were likewise establishments of the priest-caste, who, as a dominant race, had their principal seat at Meroë, whence they sent out colonies, which in their turn became builders of cities and temples, and likewise founders of states. Thus the first seats of commerce were also the first seats of civilization; exchange of merchandise led to exchange of ideas; religion readily interposed its sanction in behalf of commerce; and "by this mutual friction was first kindled the sacred flame of humanity."

ETHNARCHA, ETHNARCH (formed of εθνος, *nation*, and *αρχη*, *command*), a governor or ruler of a nation.

There are some medals of Herod surnamed the *Great*, on one side of which is found Ἡρωδου, and on the other Εθναρχου, or *Herod the Ethnarch*. After the battle of Philippi, Antony passed into Syria, constituted Herod and Phasael his brother tetrarchs, in which quality he committed to them the administration of the affairs of Judæa. Herod therefore had the government of the province before the Parthians entered Syria, or before the invasion of Antigonus, which did not happen till six or seven years after Herod commanded in Galilee. Herod was, therefore, truly ethnarch, for he cannot be otherwise denominated; so that it must have been during that period the medals were struck which gave him this title; and these medals are a confirmation of what we read in history of the government which that prince was intrusted with before he was raised to royal state. Josephus gives Herod the appellation of *tetrarch* instead of that of *ethnarch*; but the two terms come so near to each other, that it is easy to confound them together. Though Herod the Great left by will to Archelaus all Judæa, Samaria, and Idumea, yet Josephus tells us he was then only called *ethnarch*.

ETHNOPHRONES, in *Antiquity*, a sect of heretics in the seventh century, who made a profession of Christianity, but joined thereto all the ceremonies and follies of Paganism, such as judicial astrology, sortileges, auguries, and other divinations.

ETIENNE, ST, an arrondissement of the department of the Loire, in France, extending over 450 square miles. It is divided into nine cantons and seventy-six communes, and contains 107,506 inhabitants. The capital is the city of the same name, situated on the river Furand. It is a large manufacturing place for silk ribbons and other silk goods, and also for ironmongery, as well as for muskets, pistols, swords, and other weapons. It contains 16,295 inhabitants. In the neighbourhood is abundance of fossil coal. Long. 4. 15. E. Lat. 45. 22. N.

ETIQUETTE, a French term, primarily denoting a ticket or title affixed to a bag or bundle of papers, and expressing its contents. It is also used, when applied to the Spanish and some other courts, to signify a particular account of what takes place daily in the king's household, and of the chief ceremonies which are there observed. It likewise denotes those forms which regulate the decorum of conduct towards persons of various ranks and stations.

ETOILE, a town of the department of the Drome, in

France, where good wine is produced. It contains 2314 inhabitants.

ETNA, or Ætna, a volcano in Sicily. See Ætna.

ETOLIA, a country of ancient Greece. On the east it was separated by the river Evenus, now the Fidari, from the Locrenses Ozolæ, and on the west from Acarnania by the Achelous; on the north it bordered on the country of the Dorians and part of Epirus, and on the south it extended to the Bay of Corinth.

The Etolians were a restless and turbulent people, seldom at peace amongst themselves, and ever at war with their neighbours; strangers to friendship or the principles of honour; and ready to betray those who trusted them, upon the least prospect of reaping any advantage from their treachery; in short, they were looked upon by the other states of Greece as but little better than outlaws and public robbers. On the other hand, they were bold and enterprising in war, inured to labour and hardships, undaunted in the greatest dangers, and jealous defenders of their liberties, for which they were, on all occasions, willing to hazard their lives, and to sacrifice all that was most dear to them. They distinguished themselves above all the other nations of Greece in opposing the ambitious designs of the Macedonian princes, who, after having reduced most of the other states, were forced to grant them a peace upon honourable terms. The constitution of the Etolian republic was copied from that of the Achæans, and constructed with a view to form, as it were, a counter alliance; for the Etolians bore an irreconcilable hatred to the Achæans, and had conceived no small jealousy of the growing power of that state. The Cleomenic war, and that of the allies, called the Social War, were kindled by the Etolians in the heart of the Peloponnesus, with no other view than to humble their antagonists the Achæans. In the latter contest, this people, with the assistance only of the Eleans and Lacedæmonians, held out for the space of three years against the united forces of Achaia and Macedonia; but they were at last obliged to purchase a peace, by ceding to Philip the whole of Acarnania. As they parted with this province much against their will, however, they watched all opportunities of wresting it out of the Macedonian's hands; and with this view they entered into an alliance with Rome, which proved of great service to the Romans in their war with Philip; but growing insolent on account of their services, they soon made war upon their allies, by whom they were overcome, and only obtained a peace upon severe conditions. After the conquest of Macedonia by Paulus Æmilius, they were reduced to a much worse condition; for not only those amongst them who had openly declared for Perseus, but such as were suspected of having favoured him in their hearts, were sent to Rome, in order to clear themselves before the senate; and there they were detained, and never afterwards suffered to return to their native country. Five hundred and fifty of the chief men of the nation were barbarously assassinated by the partizans of Rome, for no other crime than that of being suspected of wishing well to Perseus. The Etolians appeared before Paulus Æmilius in mourning habits, and made loud complaints of this inhuman treatment; but they obtained no redress; and ten commissioners, who had been sent by the senate to settle the affairs of Greece, decreed that those who were killed had suffered justly, since it appeared that they had favoured the Macedonian party. From this time the chief honours and employments in the Etolian republic were only conferred upon those who were known to prefer the interest of Rome to that of their country; and as such persons were alone countenanced of Rome, all the magistrates of Etolia became the creatures and mere tools of the Roman senate. In this state of servile subjection they continued until the destruction of Corinth and the dissolution of the Achæan league, when Etolia, with the other free states of Greece, was reduced to the condition of a Roman province, and called the province of Achaia. Nevertheless, each state and city was governed by its own laws, under the superintendence of the prætor whom Rome sent annually into Achaia: the whole nation paid a certain tribute; and the rich were forbidden to possess lands anywhere except in their own country.

In this state Etolia continued, with little alteration, under the emperors, till the reign of Constantine the Great, who, in his new partition of the provinces of the empire, divided the western parts of Greece from the other, calling them *New Epirus*, and subjecting the whole country to the *præfectus prætorii* for Illyricum. Under the successors of Constantine, Greece was parcelled out into several principalities, especially after the taking of Constantinople by the western princes. At that time Theodorus Angelus, a noble Grecian, of the imperial family, seized on Etolia and Epirus, the former of which he left to Michael his son, who maintained it against Michael Palæologus, the first emperor of the Greeks, after the expulsion of the Latins. Charles, the last prince of this family, having died without issue in 1430, bequeathed Etolia to his brother's son, also named Charles, and Acarnania to his natural sons Memnon, Turnus, and Hercules; but great disputes having arisen about this division, Amurath II. after the reduction of Thessalonica, laid hold of the favourable opportunity thus offered, and in 1432 drove them all out. But the Mahommedans were afterwards dispossessed of this country by George Castriot, prince of Epirus; who, with a small army, opposed the whole power of the Ottoman empire, and defeated the Turks in twenty-two pitched battles. That hero, at his death, left the greater part of Etolia to the Venetians; but the latter not being able to make head against the Ottoman power, the whole country was soon reduced by Mahommed II.

ETON, or Eaton, a town situated on the left bank of the Thames, and connected with Windsor by a bridge. It is situated in the hundred of Stoke, in the county of Buckingham. The chief object of attraction is the well-endowed college, the most celebrated for the classical scholars it has produced of any institution in the kingdom. It was founded by Henry VI. in 1440, and the foundation scholars, chosen for their proficiency, are transferred to King's College, Cambridge, of which they are admitted to fellowships as vacancies arise. The buildings are in the Gothic style, well adapted for the accommodation of the provost, masters, and scholars; but those of the latter not on the foundation are boarded and lodged at houses in the town. The number of scholars is about 300. The town depends on the college, has no market, but is supplied from that of Windsor adjoining. The population amounted in 1801 to 2026, in 1811 to 2279, in 1821 to 2475, and 1831 to 3232.

ETRURIA, an ancient province or country of Italy, bounded on the north by Liguria, from which it was separated by the river Macra, now Magra; on the side of Cisalpine Gaul, by the lofty ridges of the Apennines; on the east by Umbria, from which it was separated by the river Tiber; and on the west by the Tuscan Sea. The country thus situated appears to have been one of the earliest seats of European civilization, and the principal source whence Rome derived her laws, customs, and superstitions.

ETRUSCANS, or Tuscans, called by the Greeks *Tyrrhenians* or *Tyrsenians*, and by themselves *Rasena*, were the people who inhabited ancient Etruria, and who, at a period when the rest of Europe was immerged in ignorance and barbarism, had attained to a high degree of civil and social refinement.

Etruscans.

The origin of this interesting race, from whom have descended some monuments of the earliest humanity, appears to have puzzled the ancients as much as it has perplexed the moderns; and, notwithstanding all that has been written on the subject, particularly by the Italian antiquaries, it is still beset with difficulties and involved in obscurity. The question chiefly agitated amongst the ancients was whether the Etruscans were Pelasgi from Greece, Lydians from Asia Minor, or an indigenous and aboriginal race in Italy; and the moderns have added more than an equal number to the hypotheses of the ancients. Herodotus represents them as a colony of Lydians, who, having been compelled by famine to emigrate from Asia, arrived, after various wanderings, in Umbria, where they settled and called themselves Tyrrhenians, from Tyrrhenus, son of their king Atys, the conductor of the emigration. This tradition, whencesoever derived, has been almost implicitly followed by the ancient writers; indeed Cicero, Strabo, Velleius Paterculus, Seneca, Pliny, and Plutarch, all agree in repeating the assertion that the Etruscans originally came from Lydia.

But the moderns have not in general evinced the same deference for the authority of Herodotus in this particular, and have advanced a variety of hypotheses, some of them, perhaps, not much more tenable nor better founded than the story told by the father of history. Dempster, who may be said to have laid the foundation of an accurate knowledge of Etruscan history and antiquities, is of opinion that there existed an original nucleus of inhabitants in Etruria, which was successively augmented by the Lydian immigration, and by Pelasgic colonies from Thessaly and Arcadia. Bochart coincides pretty nearly with Dempster, but maintains that there must have existed a direct intercourse between the Etruscans and Phœnicians, as many of the fables, superstitions, customs, and monuments of the former were, according to him, of oriental origin. Winckelman and the Count de Caylus, admitting an ancient communication with the East by means of the Mediterranean, substitute Egypt for Phœnicia; and to the supposed intercourse between Etruria and the land of the Pharaohs the former ascribes the remarkable progress made by the Etruscans in the sciences and liberal arts; whilst the latter is of opinion that this people borrowed every thing from Egypt, and that the origin of science and art in Etruria is coeval with the commencement of their commercial connection with that country. Improving upon these views, some writers have advanced a step further, and maintained that the Etruscans not merely carried on an intercourse with Egypt, but were actually of Egyptian descent, in fact a colony or branch of the great nation established in the Delta and valley of the Nile. This opinion has been adopted by Buonarotti, Gorius, Mazzochi, Maffei, Guarnacci, and Lord Monboddo; but it has been strenuously opposed by a number of the most learned Italian, French, and German archæologists, particularly by Bardetti, Pelloutier, Fréret, Funccius, Adelung, and Heyne, who, though differing from one another in some points, have generally contended for the northern and Celtic origin of the Etruscans. Lanzi, without pretending to investigate the origin of this remarkable people (who, he nevertheless seems to think, were Lydians, augmented at different times by the accession of Pelasgic tribes), endeavours to prove that, whatever may have been their descent, the language, religion, learning, and arts of the Etruscans, were of Greek origin; that the period of their greatest perfection in the arts of design was posterior to the subjugation of Etruria by the Romans, when the intercourse with Greece had rendered them familiar with the beautiful models of that country; and that, even admitting all languages to have been originally derived from the East, and many Greek words to have sprung from Hebrew or Phœnician roots, still there exist in the Etruscan such evident traces of Hellenic descent, particularly in the names of gods and heroes, as to render it almost impossible to derive their origin from any other source. Further, in support of this theory, the learned Italian attempts to show from the inscriptions on the Eugubine tables, that the Etruscan was Æolic Greek, without either the monosyllabic characteristics of the northern dialects, or the prefixes and affixes peculiar to most of the oriental languages. Humboldt, again, supposes this people to have been a connecting link between the Iberians and Latins, or a sort of transplanted offset from the great Celtic stem. But the learned and ingenious Müller adopts an intermediate opinion. Admitting a primitive population of Etruria, as to whose origin he does not venture to decide, he conceives that there are nevertheless grounds for assuming that they became intermingled with Pelasgic colonists from the coast of Lydia, where the latter had for a time settled, and acquired the name which they afterwards rendered notorious by their piracies in the Ægean Sea. It would be hopeless to endeavour to reconcile these conflicting hypotheses, and endless to examine their respective merits in detail.

Of all those, however, who have laboured to resolve this *quæstio vexata* in the archæology of history, Niebuhr has, we think, been, upon the whole, the most successful. The origin of the erroneous opinions as to the extraction of the Etruscans, he traces to two assumptions, which he shows to be equally fallacious: first, that the Pelasgians could only be derived from Greece, a supposition which probably gave rise to the story of the migration from Thessaly; and, secondly, that because the Mæonians were Tyrrhenians, these Tyrrhenians, like those of Lemnos, were of the same stock with the ancient inhabitants of Agylla and Tarquinii, whence arose the story of the Lydian emigration of the ancient Tyrrhenians, as told by Herodotus. But, on the authority of Xanthus, Dionysius proves that the account of Herodotus was not founded upon a Lydian tradition; and, from the complete difference of the two nations in language, usages, and religion, he justly contends that it would deserve no credit, even if there had been a tradition to the effect stated. He asserts that the Etruscans spoke a language which bore no affinity to any other known form of speech; and this assertion would deserve full credit, even if we had only the evidence of Dionysius, inasmuch as Etruscan was then, and for a considerable time afterwards, a living language, in which, as we gather from Lucretius,[1] books were written and read. It is further confirmed by the inscriptions still extant, in which every resource of etymology has failed to detect any analogy between the Etruscan and the Greek language or the kindred branch of the Latin; and these singular monuments, which have thus resisted the utmost efforts of modern scholarship and ingenuity, will to all appearance remain for ever a dead treasure, unless a key shall accidentally be furnished for their interpretation, by the discovery of a bilingual inscription. In opposition to the unanimous evidence of the ancients, who distinguish the Etruscan from the Sabine and Oscan, it has indeed been maintained that all the nations of Italy, remains of whose language occur in inscriptions, spoke only dialects of the same radical form of speech; but this opinion, which has chiefly prevailed amongst the Italian scholars, is at variance with the results of unbiassed investigation; and it appears to have been completely established that the Etruscan language, being wholly original and peculiar, bore as little affinity to the Sabine and Oscan as to the Latin and Greek, with which fanciful etymologists have vainly sought to connect it.[1]

---

[1] Non Tyrrhena retro volventem carmina frustra
Indicia occultæ Divûm percurrere mentis.

The Etruscans, during the most prosperous period of their history, inhabited Etruria proper, and the country about the Po, besides distant colonies. The Rætians and other Alpine tribes were also of Etruscan origin; and so were the Lepontians and Camunians, perhaps also the Euganeans, who inhabited Venetia before the founding of Patavium. It has been suggested by Niebuhr that the language spoken by the people of Groeden in the Tyrol, a language which seems to stand alone in its peculiar roots, may have some claims to be considered as a relic of the ancient Etruscan.[2] The Brenner formed the northern boundary of the Rætians, and consequently of the Etruscan race, who in the time of their greatness had probably occupied the mountains as a bulwark against irruptions from the north. Some, however, are of opinion that Rætia was the original home whence the Etruscan people issued, and spread first in Upper Italy, and afterwards across the Apennines; and the harshness of the Etruscan language, which seems still to survive in the Florentine pronunciation, has been adduced as an argument for the Alpine origin of the people.

In the ancient history of the Umbrians it was related that the Etruscans had conquered three hundred towns of their nation. The Umbrians, therefore, must have once occupied the greater part of the countries, including Tuscany, which the Etruscans possessed in the zenith of their power. According to the tradition of the Lydian migration, Pisa, and the whole country to the rocky summits of the Alps, were wrested from the Umbrians by the Tyrrhenians; and Pliny considers the Umbrians as the ancient inhabitants of Etruria who were expelled by the Pelasgians. Without entering into the question whether Cortona was Etruscan or not, still Cære, Graviscæ, Alsium, and Saturnia, were certainly occupied by the Etruscans as conquerors, after expelling the people called in Italy Siculians, and in Greece Pelasgians and Tyrrhenians. The Pelasgians were also in possession of Tarquinii before the Etruscans; Populonia was called a colony of the Volaterrans, who had driven the Corsicans from the coast; and Pisa is mentioned by Dionysius amongst the places which the Etruscans had wrested from the Pelasgians. But all statements, however probable or well attested, were at length forced to give way to the story of a Lydian extraction, which of necessity placed the first settlement of the immigrants on the lower sea, and thus involved the whole question in perplexity. What the native annals of the Etruscans related as to their origin we know only negatively; in them the Lydian legend which has created so much embarrassment had no place.[3] According to this view, then, there appear to have been two consecutive conquests: that of the Umbrians by the Pelasgians; and that of the Pelasgians by the Etruscans, who, as it were, absorbed all the others, and ultimately became the dominant people. The principal stock of the nation, however, seems to have been formed out of that great Pelasgian race which at one time extended from the rivers Po and Arno in Italy to the Phyndacus in Asia, but which, even when intermingled by conquest with other tribes, never succeeded in spreading itself over the whole of Northern Italy. The Etruscans, indeed, at no period of their history possessed the whole of Cisalpine Gaul. On the westward their territory extended only to the Ticinus, where dwelt the Ligurians, who were afterwards driven back by the Gauls; and the land to the south of the Po was also either occupied by the latter, or rendered uninhabitable by swamps. When the Gauls made their irruption the Umbrians were still masters of the country now called Romagna; but between the Veneti and the Gauls, Etruscan settlements maintained themselves until the time of the Romans.

---

[1] The names of Tuscan and Etruscans were as foreign to this people as that of Tyrrhenians. They called themselves *Rasena*, as already stated; and the other appellations applied to them were evidently arbitrary, accidental, or hypothetical. The ancient Roman terms were *Etruria* for the country, and *Tusci* for the people; that of *Etruscus* did not come into use till after Cato's time, though subsequently it became the more usual in the language of books. But the old name must have continued prevalent in the mouth of the people; for under the later emperors the name of *Tuscia*, which had never before been used in writing, was applied to the country, and in the middle ages passed into *Toscana*, whence *Toscani*. (Niebuhr, *History of Rome*, p. 90, Cambridge, 1828.) Professor Müller thus sums up his researches into the origin of the Etruscans: "It remains that we regard the Tuscan nation as an original and peculiar people of Italy; their language is widely different from the Greek; the names of their gods are not those which we find among the earliest Greeks, whom we call Pelasgi, and which passed from them to the Hellenes; there is much too in the doctrine of their priests entirely foreign to the Greek theology. But it appears to have been the fate of this nation, which never displayed any independent civilization, but only adopted that of the Greeks, to have been indebted for its first impulse towards improvement to a Greek, or at best half Greek tribe. The Tuscans themselves, in their native legends, referred their polity and civilization to the maritime town of Tarquinii and the hero Tarchon, both probably only variations of the Tyrrheni. Here it was that the much-dreaded Pelasgians of Lydia landed and settled, bringing with them the arts which they had acquired at home, or on their way. For the first time, the barbarous land saw men covered with brass array themselves for battle to the sound of the trumpet; here first they heard the loud sound of the Lydo-Phrygian flute accompanying the sacrifice, and perhaps witnessed for the first time the rapid course of the fifty-oared ship. As the legend, in its propagation from mouth to mouth, swells beyond all bounds, the whole glory of the Tuscan name, even that which did not properly belong to the colonists, attached itself to the name of Tarchon, the disciple of Tages, as the author of a new and better era in the history of Etruria. The neighbouring Umbrians and Latins named the nation, which from this time began to increase and diffuse itself, not from the primitive inhabitants, but from these new settlers. For since, in the Eugubine tables, *Turste* occurs along with *Tuscom* and *Tuscer*, it is impossible not to conclude, that from the root TUR have been formed Tursicus, Turscus, Tuscus; as from the root OP, Opscus and Oscus; so that Τυῤῥηνοι, or Τυρσηνοί, and Tusci, are only the Asiatic and Italian forms of one and the same name." (*Die Etrusker*, vol. i. p. 100.)

[2] Hormayr, *Geschichte von Tyrol*, p. 139. This suggestion is eminently deserving of attention and verification. For as the Etruscan alphabet is known, the determination of a few roots would serve as a fulcrum, by means of which the great lever of tentative interpretation might be applied.

[3] "It is evident," says a late writer, "that the Etruscans themselves believed that they sprung from the Lydians, and that they *inculcated this belief on others*" (Dunlop, *Hist. of Rom. Literature*, vol. ii. p. 7); and he grounds this assertion on a circumstance mentioned by Tacitus (*Annal.* lib. iv. c. 55). Eleven cities of Asia contended, it would appear, for the infamous honour of erecting an altar to Tiberius; and this ridiculous and humiliating question was argued in presence of the tyrant, before that degraded senate whom he had publicly taunted with their abject servility. On this occasion the Sardians, one of the contending parties, insisted on their affinity to the Etruscans; in proof of which they produced a decree of that people, repeating the tale told by Herodotus, and of course attesting the original confraternity of the Sardians with the ancient inhabitants of Etruria. This is the statement of Tacitus. What degree of credit may be due to a document founded upon a vague tradition, flattering to popular vanity, produced in such a cause before such judges, and as to the authenticity of which the historian is silent, our readers will not, perhaps, find it difficult to determine. The only thing surprising is, that in such a competition of servility and adulation, a grave historian should have sought for materials to support an hypothesis, improbable in itself, and at variance with the best authorities on the subject.

This people appear to have had twelve cities to the north of the Apennines, and an equal number to the south of that range. Amongst the former, of which we can give but a very indistinct account, may be classed Verona, which is denominated a Rætian city by Pliny, and Mantua, which is called Tuscan both by him and by Virgil. Hatria, Melpum, and Felsina were also included in the twelve cities north of the Apennines. Hatria, once a place of great commerce, gave its name to the upper sea; Melpum, to the north of the Po, was destroyed by the Boii, Senones, and Insubres, on the same day that Camillus took Veii (in the year of Rome 358); and Bononia, under the name of Felsina, was once the capital of Etruria. The twelve cities south of the Apennines, which were leagued together as the chief places of their respective districts, are nowhere enumerated by name; but Livy incidentally mentions eight of them, namely, Cære, Tarquinii, Populonia, Volaterra, Arretium, Perusia, Clusium, and Rusellæ, as having contributed to forward Scipio's preparations. Cortona was also accounted one of the chief places in Etruria, and both Veii and Vulsinii were probably included in the original number. But whether Capena, or Cossa, or Fæsulæ, completed the twelve, it is now impossible to decide. The changes produced by time and by conquest have involved this part of the subject in impenetrable obscurity.

The territory belonging to each of these capitals had several provincial towns, some of them dependent colonies, and others inhabited by subjects, the descendants of the old population who had been subdued. But as the Etruscan state was founded on conquest, the government naturally assumed the character of an aristocratical oligarchy. It was not by popular assemblies, nor even by the deliberations of a numerous senate, but by meetings of the chiefs or magnates of the land (*principes Etruriæ*), that the general affairs of the nation were decided on. The assemblies held at the temple of Voltumna were of this exclusive kind, and hence in no degree corresponded with the institutions of really free nations, such as the Latins and the Samnites. These Etrurian chiefs were the persons from whom the Roman youth received instruction in the sacred sciences of divination; they were at once a warlike and sacerdotal caste, the Lucumones whose ancestors had committed to writing the revelations of Tages. But they were patricians, not kings, as has been commonly supposed. Lucumo of Clusium, Lucumo who succoured Romulus, and Lucumo who removed from Tarquinii to Rome, were only powerful men in their respective cities; the Cilnii and Cæcinæ were Lucumones in Etruria, just as the Claudii and Valerii were patricians in Rome, and were not less noble in birth than the latter, though, as Romans, reckoned only amongst the commons. But these ruling houses were exposed to the violent revolutions which everywhere threaten an oligarchy, even in the midst of its own body, when it is not upheld by some powerful protection from without. The chiefs expelled each other by force of arms, or were driven into exile by the combinations of intrigue; and it was in the spirit of these feuds for the refugees to be restored by the dangerous mediation of the common enemy, the Romans. Even so late as the second Punic war, the government of the Etruscan cities remained exclusively vested in the senators, or nobility; the latter were, what Louis XIV. called himself, the state; and, when a ferment began in Etruria, it was entirely suppressed by securing the submission of the senate at Arretium. The people, who had no political existence as such, were out of the question. A free and respectable commonalty was never formed amongst the Etruscans; on the contrary, the species of feudal system, anciently established by conquest, was obstinately maintained and extended; the mass of the population were mere serfs; and hence arose the remarkable weakness of the great Etruscan cities in their contests with Rome, when the victory was to be determined by a numerous, brave, and steady infantry. National impotence ever follows the degradation of the people. What the Etruscans might have been if, some centuries earlier, they had had a country, is evinced by the effect of the Roman franchise conferred upon them at the conclusion of Sylla's war. In this contest the part taken by the chiefs was taken by all; and every free man, however excluded or restricted by the old but now expiring constitutions of his own country, obtained the privileges of Roman citizenship; nor was the boon either undeserved or misapplied.

The regal office, which was not hereditary in a single family, as in Greece, but elective for life, as at Rome, continued at Veii until its fall. At Arretium, however, the king may perhaps have been chosen from amongst the Cilnii, a family of high distinction. The twelve federal cities nominated a common high priest, who presided at the national festivals. In common enterprises the supreme command was generally committed to one of the twelve Lucumones, who received a lictor from each city. Even Porsenna, highly as he is celebrated in the old legends, is in Roman history only king or chief of Clusium; yet he had influence sufficient to set the whole power of the nation in action. In like manner all the twelve cities paid homage to Lucumo Tarquin; and in the earlier times a closer union seems occasionally to have been effected by the power of a supreme chief, as Mezentius or Cœles Vibenna. But such union appears to have been the exception rather than the rule, and to have depended on accident rather than on organization; nor have we been able to discover satisfactory evidence of the existence of a distinct federal constitution, such as some writers have rather gratuitously imagined. Yet loose as was the federal bond in Etruria, it seems to have had the effect of preventing wars between the cities, of which no trace is to be found in history. Such, then, being the nature of their association, it is probable that the islands subject to the Etruscans were not under the dominion of the whole nation, but under that of the adjacent maritime cities; and, accordingly, it seems as if the Cærites stood alone when, leagued with the Carthaginians, they attacked the Phocæans of Alalia, which happened in the year of Rome 220. The principal insular dependency of the Etruscan states was Corsica, which paid them a tribute; but it is not improbable that they had also settlements in the island of Sardinia.

The maritime cities of Etruria having early engaged in navigation, were stigmatised and hated on account of the piracies they committed in the western seas, which, anterior to the founding of the Grecian colonies in Sicily, were thus rendered impassable to peaceful navigators. Niebuhr is, however, inclined to think that this reproach may have applied chiefly to the Pelasgian Tyrrhenians, whom the Etruscans afterwards subdued; and indeed all the corsairs of the lower sea seem to have been considered by the Greeks as Tyrrhenians. But without entering into any details respecting their nautical adventures, whether piratical or other, it may be observed, that navigation naturally implies an interchange of commodities; and a fruitful land, rich in internal treasures, supplied abundant materials for the commercial spirit in Etruria. From a very early period the Etruscan maritime cities appear to have engaged in commerce; and in the time of Aristotle, treaties, by which the rights of trade were respectively determined and secured, subsisted between these cities and Carthage. Amongst the subjects of this commerce may be mentioned the produce of the iron mines of Elba,[1] and of others upon the mainland of Etruria, which yielded a more abundant supply of a purer kind of metal than any in the ancient world. The same island also furnished copper for their coinage, and for those works in brass or bronze in which they so greatly excelled. Müller supposes them to have also traded in amber, which substance, he thinks, they received by an inland route, extending from the shores of the Adriatic to those of the Baltic; but as his chief reason for this supposition appears to be, that, in Pliny's time, amber was conveyed by the same route into Italy, and as no safe conclusion can be drawn respecting the extent of early communications, from those which are found established at a later period, when circumstances had wholly changed, the conjecture in question must, we suspect, be dismissed as untenable. On the subject of Etruscan commerce, however, the information which has reached us is too scanty and imperfect to enable us to deduce any distinct conclusions, either as to the extent to which it was carried on, or the particular channels in which it flowed.

The works constructed by the Etruscans still astonish us even in their ruins, and could scarcely have been executed in small states without taskmasters and bondsmen. The everlasting monuments of Egypt are the products of the direst tyranny acting remorselessly upon the most abject slavery. But the scarcely less durable works of the Etruscans differ from those in the valley of the Nile, in having all of them been directed towards some great object of public utility. Labour was not uselessly or wantonly expended in the erection of pyramids, obelisks, and temples, to gratify the inordinate vanity of despots, or to extend the empire of superstition; if the people suffered in the hard service imposed on them, it was not for vain or idle purposes; they were employed by their rulers on whatever seemed best calculated to promote the defence or augment the wealth of the nation at large. The walls of their cities, constructed of huge blocks of polygonal stones, still ubsist in imperishable solidity, where pains have not been aken to demolish them; the theatre at Fiesole, and a colossal building near it, are on a scale of equal grandeur; and other monuments might be mentioned which have been constructed in the same Cyclopean style. The ich valley of the Arno, anciently a lake and a swamp, was drained by means of a cut through Mount Gonfalina, which blocked up the valley, but which, by means of this operation, was made to afford a passage for the stream owards Pisa; the arms, too, by which the Po discharges tself, were also excavated or directed by the Etruscans; nd its Delta was likewise the fruit of their labours. Anther useful art practised by this people consisted in leting off, by means of tunnels, lakes which had been formed in the craters of extinct volcanoes. In the territory of Perugia there are traces of many such lakes, which have een completely dried up, by means of the tunnels, which, hough now unknown and never cleared out, still drain off he water as before.

The renown which belongs to a nation that excelled in he arts has become as it were the inheritance of the Etruscans. But from the peculiar constitution of government and society in ancient Etruria, it has been conjecured, not without appearance of reason, that the works in ronze and clay, and the bas-reliefs, attributed to them, were the produce, not of the dominant race, but of their subject bondsmen or serfs; and that in reality the Etruscans, properly so called, were as little given to the arts as the Romans by whom in their turn they were subdued. The striking difference observable between Tarquinii and Arretium in their works of art, seems to correspond with the different origin of the earlier inhabitants of northern and southern Etruria. Volaterra was naturally led, by the stone quarries in its neighbourhood, to engage in the works for which it became celebrated. The two former cities, however, wrought only or chiefly in clay. Arretium made red vases, with elegant figures in relief, in a style altogether peculiar. Those of Tarquinii were painted, and both in colour and design resemble some discovered near Corinth, of which Dodwell has given engravings. Painted vases are found only in the district of Tarquinii, and where they occur those of Arretium are never met with; besides, they differ from the Campanian in all those peculiarities for which the Greek works of the same kind are distinguished. The resemblance which is thus found to exist between the vases of Tarquinii and of Corinth irresistibly reminds us of the story of Demaratus, who is said to have been accompanied by the potters Euchir and Eugrammus; a circumstance evidently designed to express that Tarquinii derived from Greece her skill in handling clay, and the elegant drawing with which her vases were adorned. The earliest Etruscan statues were of clay; but the statues belonging to the first ages of Rome were almost uniformly of bronze, and the master-pieces which shed lustre on Etruscan art are all of the same material. That this art received its refinement from the Greeks cannot, we think, be reasonably questioned. Works of primitive antiquity attest its original rudeness; and to the Greeks alone, improving on Egyptian models by a close study of the finer forms and proportions of nature, belonged that skill which throws life and beauty into the delineation of the human figure. Hence the subjects of many of the most beautiful Etruscan works of art are obviously taken from the Greek mythology, which, in Etruria, was found as well adapted to the purposes of the artist as in the land to which it was native. But the Etruscans, when their taste had once been formed, treated their own conceptions in the spirit of their masters; and, though no doubt inferior in grace and delicacy of execution, they acquired a correctness in drawing which may almost be stated as a national characteristic. In the she-wolf of the Capitol we have an example of the perfection to which Etruscan art had attained about the middle of the fifth century of Rome; nor are the finest gems probably of a much more recent date.

As a national heroic story was wanting to Etruscan art, it sought for subjects in the Greek mythology; and the legends of Thebes and of Ilium must have been familiar to the people. The Greek poems were read in Etruria, and Greek legends, transfused into Etruscan, lived in the speech of the nation, or in compositions in the native tongue. Indeed the works of art are not unfrequently inscribed with the names of the Greek heroes, adapted to the forms of the Etruscan language, of which it is matter of regret that so little is yet known. Varro mentions Tuscan tragedies by one Volnius, who, it appears, lived not long before, and probably intended these as an experimental attempt to introduce a national drama. But be this as it may, the Grecian construction of the theatre at Fæsulæ is evidence that Greek dramas, either originals or translations, were performed there, as well as at Tusculum and Bovillæ in Latium; nor can it be doubted that this

---

[1] Insula inexhaustis chalybum generosa metallis. (*Æn.* x. 174.)

Etruscans.

theatre is much earlier than the time of Sylla, since in size and magnificence it far surpasses the scale of a Roman military colony, which, besides, cannot be supposed to have had any taste for the exhibitions peculiar to such a place. The amphitheatre was the only place to which such colonists would have repaired for amusement. It is proper to add, however, that in Etruscan inscriptions we do not find any thing bearing the slightest resemblance to Greek rhythms, which could scarcely have been concealed even in an unintelligible language; and that the place whence the Fescennine musical dialogue received its name was a Faliscan, not an Etruscan town.

The music of the Romans was derived from Etruria, whence also they obtained their scenic or histrionic singers. This is the only branch of art in which the ancients attributed to the Etruscans the honour of invention; but here the invention related merely to the instrument; for we do not read of any mood or measure ascribed to the Etruscans. This instrument was the flute, which the Romans regarded as native to Etruria, though modern antiquarics pretend that it is to be considered as of Lydian origin, and even as a proof of the Lydian immigration mentioned by Herodotus. The celebrity which the Etruscans obtained in music, as well as in other accomplishments, was, no doubt, in part owing to their having been the neighbours of a rude and uncultivated people like the Romans, who naturally admired whatever was new or strange, and who, until they became acquainted with the Greeks, derived all that was ornamental in their system of public and private life from Etruria.

The literature of the Etruscans presents the singular phenomenon of an alphabet almost perfectly deciphered, with a language completely unintelligible. A combination so strange has led more than one writer to maintain that the language is Pelasgic or Æolic Greek, and to appeal in proof of this to the alphabet; but, unfortunately, there is a total want of connection between the premises and the conclusion; and the result of all the investigations yet instituted has been to disprove this notion. The Etruscan characters were formed like the Greek, from that one amongst the various Asiatic alphabets whence all the modes of writing in use throughout Europe appear to have been derived. That Etruria received them directly from the Phœnician would not certainly be proved by the direction of the writing from right to left; but when to this we add the omission of the short vowels, the practice of noting double consonants by a single letter, as in all the Aramaic systems of writing, and the want of the vowel O, which are peculiarities purely Punic, the presumption in favour of Phœnician origin is considerably increased. From this last circumstance, however, nothing can be decisively determined as to the pronunciation, inasmuch as the Semitic languages are not defective in the vowel, which is wanting to the Etruscan. The Phœnicians also distinguished numbers by letters; but not so the Etruscans. What we denominate the Roman numerals are of Etruscan origin, and occur frequently on their monuments, being probably the abbreviated remnants of a hieroglyphical art of writing in use before the alphabetical, and, like the Aztecan numerals, representing objects connected with particular numbers. Niebuhr thinks them indigenous to the west. But however this may be, the literal form which these numerals have now assumed cannot mislead any one as to their hieroglyphical origin. With respect to the Etruscan language, which remained harsh in sound and uncouth in its forms, all the labour which has hitherto been bestowed in attempting to interpret it, though valuable for its collateral results, has proved wholly fruitless in reference to its direct object. Lanzi, abandoning the oriental and northern etymology, endeavoured to explain the Etruscan from the Pelasgic; and for many years after the appearance of his Essay, his explanations were acquiesced in, and even made the basis of various etymological hypotheses. But when at length credulity gave place to inquiry and examination, it was perceived that his modes of proceeding were much too arbitrary; that he had produced no evidence of the existence of the words and forms which he had assumed to be Greek, in order to identify them with the Etruscan; and that other monuments, discovered since his time, could not in any way be explained by his system. In short, his interpretation was purely tentative and conjectural, without even accidental felicities of supposition; and hence, of all the Etruscan words, of which pretended explanations have been given, only two (AVIL RIL, *vixit annos*, or rather perhaps *ætatis annos*) seem to have been really interpreted. Professor Müller's observations on this subject are well deserving of attention, especially in reference to the expectations which appear to be entertained of the enlargement of our historical knowledge by the comparison of languages.

"We might give much ampler satisfaction," says he, "if, after Lanzi's method, we sought in the monuments of the Etruscan language for single sounds resembling the Greek and Latin, and, persuaded that similar sounds must have a similar meaning, endeavoured to explain all that could not be brought to agree, by an arbitrary prothesis, epenthesis, paragoge, and similar cheap expedients. Without blaming the learned Italian, in whose time the most eminent literati had very confused ideas of the formation of language, we may maintain that his leading principle (that analogy is the character only of cultivated languages, and that the ruder any language is, the greater liberty might be taken in the use of it) is entirely false. This may justify us for having paid so little regard to etymologies, which, as they are arbitrary in themselves, suppose an arbitrary character in the language to which they are applied. If we use only genuine monuments, and require a certain evidence for every explanation of a root or a grammatical form, our apparent knowledge of the Etruscan language shrinks almost to nothing....... It is not probable that the application of the still existing remains of the languages of the north and north-west of Europe should have those beneficial results for our knowledge of Etruscan which some appear to anticipate. The Germans and Celts are originally divided in a very marked manner, by their locality, from the nations of the Mediterranean; they only gradually approach these and come into collision with them; and even though the languages of both nations may belong to that great family which from time immemorial has diffused itself throughout Europe and Asia, yet they have distinct peculiarities, which we have no reason to believe are found in those of Italy. One fundamental and indelible characteristic of the Celtic languages seems to be, that they mark grammatical forms by aspiration and other changes of the initial consonants; a thing not practised in any other European language, but found in all the branches of the Celtic, as the Welsh, Cornish, Gaelic, Irish, and *Bas Bréton*. This mutability of the consonants is a circumstance which must be perceptible even in a small number of written remains, and which could not well have escaped us had the Etruscan been Celtic. The Iberian family, once widely diffused on the shores of the Mediterranean, may have dwelt in close vicinity to the Etruscans; but the remains of its language in the Basque are completely different from the rest of Europe; and its grammar shows so little affinity with what we know of the Etruscan, as to afford very slight support to the opinion of the affinity of the two nations. What may have been the relation of the Tuscan to the extinct Ligurian, or to the language of those Alpine tribes whose names alone are preserved in history, is a question respecting which we have not even a glimmering of knowledge."[1]

Any attempt indeed to interpret the Etruscan, without the aid of bilingual inscriptions, such as those on the Rosetta stone and obelisk of Philæ, which afforded a key to the Egyptian phonetic hieroglyphics, will be pure loss of labour. The discovery of such monuments, however, is, in regard to time and manner, an incalculable event; but still it is within the range of probable calculation; and the age which has witnessed the interpretation of Egyptian hieroglyphics by means of such aids should not hastily despair of any thing. If a translation were discovered, not in Latin or Greek, but in Oscan or even Umbrian, the latter have so much affinity to the Latin, that much might be learned from such a version for the explanation of the Etruscan. We repeat, however, that without the aid of bilingual inscriptions, the language of ancient Etruria is likely to remain as great a mystery as the inscriptions of Persepolis, or the arrow-headed legends contained on bricks found amidst the ruins of Babylon.

Of the early history of Etruria we can only collect a few detached facts of little importance, which are to be gleaned from Livy, and from short notices in the Greek historians and poets; and must ever deplore the loss of the works of Aristotle and Theophrastus on the civil institutions of the Tyrrheni, as well as regret that the history of the Emperor Claudius has disappeared. We find this people engaged in a contest with Tarquinius Priscus (about 610 B. C.), but obliged to acknowledge at least a nominal dependence on the power of Rome. They joined the Carthaginians in an attack on the Phocæans, who having left Asia Minor (about 547 B. C.) to escape the persecutions of Cyrus the elder, had settled in Corsica, and threatened to dispute with them the supremacy of the western seas. For the next two centuries they appear to have enjoyed tranquillity; until, roused to exertion by the ever encroaching spirit of the Romans, they determined to make an united effort to check the power of their dangerous neighbours. The hostile forces met (309 B. C.) near Lake Vadimon, which is still to be seen on the east of Etruria, near the Tiber, below the modern village of Bassano; and the result was, as usual, favourable to the cause of Roman supremacy. The Tuscans were completely defeated; and from this moment were compelled to co-operate in extending and strengthening the power of the conqueror. They now became incorporated with the Roman people, and can no longer be considered as a separate nation.

For a detailed account of this people, see Micali *L'Italia avanti il dominio dei Romani*, Milan, 1825, with *Antiqui Monumenti per servire all' Opera intitolato* L'ITALĪA, &c., Firenze, 1821; *L'Italie avant la Domination des Romains*, with historical notes and illustrations by M. Raoul-Rochette, Paris, 1824, in 4 tomes; Niebuhr's *Roman History*, English trans., Cambridge, 1828, in 2 vols.; Müller, *Die Etrusker, vier bucher*, Breslau, 1828; Inghirami, *Monumenti Etruschi, o di Etrusco nome*, 1821–1825, in 6 vols. 4to; Heyné, *Etrusca Antiqua*, Nov. Soc. Götting. 1766; and Gori, *Museum Etruscum*. For the ancient language of Etruria, see Dempster, *De Ætruria Regali*, Florence, 1723, in 2 vols. fol.; Lanzi, *Saggio di Lingua Etrusca, e di altre Antiche d'Italia*, 1789, in 3 vols. 8vo; and Müller, *Die Etrusker*, above referred to. (A.)

ETSCH, a circle in the Austrian province of Tyrol, which extends over 1400 square miles, comprehending three cities, three market-towns, 310 villages, 12,094 houses, and 99,782 inhabitants. The chief place is Botzen.

ETTLINGEN, a city, the capital of a bailiwick of the same name, in the duchy of Baden, in Germany. It contains 398 houses, and 3429 inhabitants, employed in cotton manufactures, and in making paper, oil, and gunpowder.

ETTMULLER, MICHEL, an eminent physician, was born at Leipsic, on the 26th of May 1644. After having studied the learned languages, the mathematics, and philosophy, first in his native town, and afterwards at Wittenberg, he returned to Leipsic, and, having devoted himself wholly to medicine, obtained the degree of bachelor in 1663, and a license or diploma in 1666. But being desirous to extend his acquirements, which were already considerable, he resolved, before taking his last degrees, to visit the countries most celebrated for the cultivation of the sciences; and with this view he commenced an interesting course of travels in Italy, sojourning for some time in the more remarkable cities of that fine country, as Naples, Rome, Florence, Bologna, Venice, Padua, Pisa, Pavia, Milan, and Turin. He then crossed the Alps and proceeded to Paris, where he remained seven months; after which he passed over into England, and thence repaired to Holland. His intention was to employ an entire winter in attending the prelections of learned professors in the university of Leyden; but his design in this respect was thwarted by his sudden recall to Leipsic, where, on the 20th of August 1668, two days after his arrival, he received the degree of doctor, a distinction which proved the forerunner of new dignities. The Academy of the Curious in Nature admitted the young doctor one of its members in 1670, and the Faculty of Medicine in 1676. About the same time the university of Leipsic confided to him the chair of botany, and appointed him extraordinary professor of surgery; offices the duties of which he discharged with distinction. But he did not long enjoy his preferment; for, on the 9th of March 1683, he was suddenly cut off, in consequence of a hectic fever, occasioned, as some say, by a chemical experiment. Although Ettmuller only wrote short dissertations and mere *opuscula*, he nevertheless enjoyed an immense reputation. His feeblest productions were reprinted, translated, and commented on; nor were his lectures, collected by numerous auditors, sometimes with much inaccuracy, less favourably received by the public. He had the art of interesting and fixing the attention by a ready elocution, and by arguments much more specious than solid. Of this any one may satisfy himself by the perusal of his works, of which the following is a list: 1. *De Singularibus*, a thesis defended by Ettmuller in 1663; 2. *Medicina Hippocratis Chimica*, Leipsic, 1670, in 4to; 3. *Vis Opii diaphoretica*, Leipsic, 1679, in 4to; 4. *Chimia Rationalis ac Experimentalis curiosa*, Leyden, 1684, in 4to; 5. *Medicus Theoria et Praxi generali instructus*, Francfort and Leipsic, 1685, in 4to; 6. *Opera Omnia theoretica ac practica*, Lyons, 1685, in 4to; 7. *Opera Omnia; nempe Institutiones Medicinæ cum Notis, etc.* Francfort, 1688, in fol.; 8. *Opera Medica theoretico-practica*, Francfort, 1676, 2 vols. fol.; 9. *Operum Omnium Medico-physicorum editio novissima*, Lyons, 1690, 2 vols. fol.; 10. *Opera Omnia in Compendium redacta*, London, 1701, and Amsterdam, 1702, in 8vo. But of all the editions, the best is that which the son of the author published under the title of *Opera Medica theoretico-practica per filium Michaelem Ernestum, etc.* Francfort, 1708, in 3 vols. fol. There is no complete translation of the works of Ettmuller, but there are numerous German, English, and French translations of the different treatises.

Michel Ernest Ettmuller, son of the preceding, born at Leipsic in 1673, was also a physician of some eminence.

---

[1] *Die Etrusker*, vol. i. p. 64, *et seq.*

Besides collecting and editing the works of his father, which formed the principal labour of his life, he wrote a number of theses and memoirs, which are not destitute of merit, and died on the 25th September 1732. (A.)

ETYMOLOGY, that branch of grammar which explains the origin and derivation of words, and which has for its object to arrive at their primary signification; for which reason Quintilian calls it *originatio*. The word is formed from the Greek, ετυμος, *verus*, true, and λεγω, *dico*, I speak; and hence Cicero calls etymology *notatio* and *veriloquium;* though Quintilian chooses rather to denominate it *originatio*.

A judicious inquiry into etymologies is thought by some to be of considerable use, because nations who value themselves for their antiquity have always looked upon the antiquity of their language as one of the best titles they could plead; and the etymologists, by seeking the true and original reason of the notions and ideas attached to each word and expression, may often furnish an argument of antiquity, from the remaining traces thereof, compared with the ancient uses. Add to this, that etymologies are necessary for the thorough understanding of a language. For, to explain a term precisely, there seems a necessity for recurring to its original import, in order justly and satisfactorily to explain its meaning in its secondary applications. The force and extent of a word is best conceived when a person knows its origin and etymology.

It is objected, however, that etymology is in some measure arbitrary, and built altogether on conjectures and appearances; and the etymologists are charged with deriving their words from whatever source they please. Nor indeed is it an easy matter to go back into the ancient British and Gaulish ages, and to follow, as it were, by the tract, the various imperceptible alterations which a language has undergone from age to age; and as these alterations have sometimes been merely owing to caprice, it is easy to assume a mere fancy or conjecture as a regular analogy; so that the public may easily be prejudiced against a science which seems to stand on so precarious a footing. It must be owned, however, that etymologies are frequently so far fetched as sometimes to render it impossible to perceive any resemblance or correspondence between roots which are alleged to be identical. Quintilian has shown that the ancient etymologists, notwithstanding all their learning, adopted very ridiculous derivations.

EUBAGES, an order of priests or philosophers among the ancient Celtæ or Gauls. According to some, the Eubages were the same with the Druids and Saronidæ of Diodorus; but others maintain that they were the same with what Strabo calls Evates.

EUBŒA, a long narrow island, now called *Negropont*, which stretched along the east coast of Greece from the Sinus Maliacus, to nearly the most southern point of Attica. Its length was 1200 stadia according to Strabo, 150 miles according to Pliny, but its greatest breadth is nowhere more than 150 stadia, or eighteen miles and a half. High and rocky mountains rendered the eastern coast unfit for habitation, but on the side opposite the mainland, where the ground became more level, there were several good harbours, and in ancient times cities of no inconsiderable importance. The island produced corn in sufficient quantities to serve as the granary of Athens. It possessed warm baths, iron mines in the vicinity of Chalcis, and salt, which Pliny considered as equal in purity to that of Attica. The mountains furnished wood in large quantities; but as the fir was liable to rot, it was of little use for ship-building.

Its inhabitants were composed of several distinct races. In the south dwelt the Abantes, mentioned by Homer; and in the north were the Histiæi, who had probably passed over from Thessaly, where we find a district of that name. The Leleges and Dryopes are also said to have occupied a part of the island.

The attack of the Persians must have tended considerably to weaken the strength and power of its inhabitants. Eretria, one of its most flourishing cities, paid the penalty of having assisted its compatriots the Ionians, by being razed to the ground, and its people carried off to the remote regions of Asia. Before the period of the Peloponnesian war it seems to have been wholly subject to the sway of Athens, but towards the conclusion of the contest it succeeded in recovering its independence. The Eubœans, however, do not appear to have gained much by this change; for they became a prey to domestic feuds, and were at length glad to acknowledge their ancient dependence on Athens. They continued in this state till the Macedonians had succeeded in annihilating the maritime supremacy of the Athenians, when the principal cities of Eubœa were garrisoned by the troops of Macedon. The Romans once more restored it to freedom. (Thucyd. i. 114, viii. 5; Diodor. xv. xvi.; Liv. xxxiv. 51; Strab. x. 444.; Plin. iv. 12.) For a more full description, the reader may consult Mannert, *Geographie des Griechenlandes*, Leips. 1822 (vol. viii. p. 244). See NEGROPONT.

EUCHARIST, the sacrament of the Lord's supper. The word in the original Greek, Ευχαριστια, literally imports *thanksgiving;* being formed from ευ, *bene*, well, and χαρις, *gratia*, thanks. This sacrament was instituted by Christ himself; and the participation of it is called *communion*.

As to the manner of celebrating the eucharist among the ancient Christians; after the customary oblations were made, the deacon brought water to the bishops and presbyters, standing round the table, to wash their hands; according to the words of the psalmist, "I will wash my hands in innocence, and so will I compass thy altar, O Lord." Then the deacon cried aloud, "mutually embrace and kiss each other;" which being done, the whole congregation prayed for the universal peace and welfare of the church, for the tranquillity and repose of the world, for the prosperity of the age, for propitious weather, and for all ranks and degrees of men. After this followed the mutual salutations of the minister and people; and then the bishop or presbyter, having sanctified the elements by a solemn benediction, broke the bread, and handed it to the deacon, who delivered it to the communicants; and in like manner afterwards the cup. The sacramental wine was usually diluted or mixed with water. During the time of administration hymns and psalms were sung; and the whole concluded with prayer and thanksgiving, upon which the people saluted each other with the kiss of peace, and so the assembly broke up.

EUCHITES or EUCHITÆ, a sect of ancient heretics, who were first formed into a religious body towards the end of the fourth century, though their doctrine and discipline existed in Syria, Egypt, and other eastern countries, before the birth of Christ. They were so called because they prayed without ceasing, imagining that prayer alone was sufficient to save them. They rested chiefly on the injunction of St Paul, *Pray without ceasing.* The name is formed from the Greek, ευχη, *prayer*, whence ευχιται, the same with the Latin *precatores*. They were also called *Enthusiasts* and *Messalians*, terms denoting the same thing as Euchites.

EUCHOLOGIUM, Ευχολογιον, a Greek term, signifying literally *a discourse on prayer*. The word is formed form ευχη, *prayer*, and λογος, *discourse*. The euchologium is properly the Greek ritual, in which are prescribed the order and manner of every thing relating to the order and administration of their ceremonies, sacraments, ordinances, and the like. Gore has given an edition of the Greek euchologium in Greek and Latin, with notes.

EUCLID of Megara, a distinguished philosopher and logician, who flourished about 400 years before Christ. The Athenians having prohibited the Megareans from entering their city on pain of death, this philosopher disguised himself in women's clothes, in order to attend the lectures of Socrates. After the death of Socrates, Plato and other philosophers went to Euclid at Megara, in order to shelter themselves from the tyrants who then governed Athens. Euclid admitted but one chief good, which he sometimes called God, sometimes Spirit, and sometimes Providence.

Euclid of Alexandria, author of the most ancient elements of geometry which have come down to us, and for this reason justly regarded as one of the fathers of science. He has been sometimes confounded with Euclid of Megara, the disciple of Socrates, and the founder of a philosophic sect who pushed to an extreme the subtilties of dialectics. The place of his birth is unknown. But Proclus Diadochus, one of his commentators, informs us that he opened a school of mathematics in Alexandria in the reign of Ptolemy the son of Lagus; and Pappus extols his kindness and affection for those who laboured to advance the study of geometry. This being all that is known of the life and character of Euclid, it only remains therefore to speak of his works, some of which have been lost. Amongst those which we possess, however, the most remarkable is that which is simply entitled *Elements*, as if to indicate that it contained the entire body of principles upon which the pure mathematics then rested. This work now consists of fifteen books; but the last two are attributed to Hypsicles, a mathematician of Alexandria who flourished at a later period. Euclid, however, neither was nor could be the inventor of all that is contained in his work; for geometers more ancient than he, including Hippocrates of Chio, had written Elements; but, on the other hand, there can be little doubt that he added to the pre-existing stock of elementary truths, improved the demonstrations in which his predecessors had failed, and composed a whole which, by more severe forms of reasoning, and a more exact concatenation of propositions, superseded all works of the same description which had been previously written, and became the basis of instruction in the mathematics. These *Elements* were first commented on by Theon, and by Proclus; but whatever success such commentaries may have had in the school of Alexandria, they remained wholly unknown to the occidentals of the middle ages, who derived all their knowledge of geometry, such as it was, from the works of Boecius, and from a production entitled *De Principiis Geometriæ*, ascribed to St Augustin.[1] It was only in the twelfth and thirteen centuries that Athelard in England and Campano in Italy laboured to decipher and translate Euclid from the Arabic versions, including the commentary of the Persian geometer Nazir-Eddin, which was held in great estimation among the Saracens; for although there is reason to believe that Boecius had made a complete Latin translation of Euclid, it has not come down to our times; and, in fact, it was not till long after the revival of letters, and when versions had been multiplied by means of the press, that a part of the *Elements* of Euclid was introduced into the course of instruction in the schools. In order to form an idea of the entire work, however, it may be considered as composed of four parts. The first of these parts comprehends the first six books, and may be divided into three sections, viz. the demonstration of the properties of plane figures treated in an absolute manner, as in books first, second, third, and fourth; the theory of the proportions of quantities in general, which is the object of the fifth; and the application of this theory to plane figures, as in book sixth. The second part contains the seventh, eighth, and ninth books, which are denominated *arithmetical*, because they treat of the general properties of numbers. The third part consists only of the tenth book, in which the author considers in detail incommensurable quantities, and which he terminates by proving that the diagonal of a square and its side cannot have a common measure; a doctrine, we may add, which is much more ancient than Euclid, since Plato, towards the close of his seventh book of *Laws*, pronounces those who have no idea of such incommensurability as sunk in almost brutish ignorance. The fourth part, which is composed of the last five books, treats of planes and solids. But of all this great body of geometrical doctrine, the only portions which have been considered as adapted to the purposes of instruction are the first six books, together with the eleventh and the twelfth; the propositions which they contain having formed the basis of all the elements of geometry which, under whatever form, have from time to time been given to the world. The fifth book, however, has often been omitted in such publications, because the notation of our arithmetic, and still more that of our algebra, have greatly simplified the theory of proportions; and, for the same reason, the other arithmetical books, which it is now difficult to read, are justly considered as more curious than useful. But, in borrowing their materials from the work of Euclid, modern authors have frequently altered the arrangement; and on this subject there have arisen two contradictory opinions, which have been debated with very great warmth, yet still remain as irreconcilable as ever. The concatenation established by Euclid, and even the forms which he has employed in demonstrating his propositions, are regarded by some as almost the last term of perfection in works of this kind; whilst others, again, have considered these as mere essays, which, however excellent in themselves, leave room for the introduction of a more natural order and more simple demonstrations. Ramus, who declared war on the dialectics of Aristotle, accuses Euclid of omissions and redundancies, and expresses his conviction that it was with reference to these imperfections that Ptolemy inquired if there were not a more easy method than that usually employed for learning geometry; an inquiry which, as is well known, elicited from Euclid the reply, that in the mathematics there was no road for kings. Antony Arnauld, and the author of the Logic of Port-Royal, have also blamed the order followed by the Greek geometer, and disputed some of his definitions;[2] but if Arnauld, either from not being very profound in the mathematics, or by reason of the great difficulty of the subject, failed, as Ramus and so many others had done, in the changes which he attempted to introduce into the *Elements*, his reasons for making the attempt still remain in all their force. For, whatever may be said to the contrary, it is certain that they are deficient in that order which, causing the propositions, as far as possible, to arise out of one another, exhibits in full evidence the analogies which connect them, assists the memory, and prepares the mind for the investigation of truth. But whether, in the actual state of the science, it be practicable to reconcile this order with the rigour of demonstration, or to obviate objections the force of which, abstractedly considered, cannot be disputed, is a question which it would far exceed the limits of this notice to discuss.[1] If it be resolved affirmatively, which appears to us possible, then no reason would exist for giving an absolute preference to the *Elements* of Euclid. As a precious relic of antiquity, and as one of those works of science which time has thrown least in arrear of actual knowledge, the *Elements* would doubtless continue to be classed in the first rank of mathematical productions; but their too arbitrary arrangement, and the style in which they are written, sometimes too prolix and at other times too concise, would no longer constitute the essential character of the geometric or synthetic method, in opposition to the analysis of the moderns. The true difference of these two methods of treating the science of quantities consists in this, that the one is founded on the immediate consideration of the properties of figures, whilst the other employs arbitrary signs, combined by the operations of calculation. The first is geometry itself, not that of Euclid more than of any other; the second is an application of algebra, which ought not to be confounded with analysis, inasmuch as synthesis may be effected with algebraic signs as well as with the figures of geometry. The latter, however, which may also be treated analytically, presents operations equivalent to the resolution of certain equations. Of this some propositions contained in the book of *Data* are remarkable examples; propositions which, by a natural and certain path, lead to the solution of problems otherwise undiscoverable. The book of *Data* was particularly relished by Newton, who, persuaded that a proposition scarcely deserved to see the light unless it could be demonstrated without the assistance of calculation, conceived that a more profound study of this treatise would have enabled him to dispense with the aid of such an instrument. But it may well be doubted, to say nothing more, whether his successors, by pursuing a similar path, would have ever attained those great and striking results which they have derived from the new methods of calculation. Besides the *Elements* and the *Data*, which are the most important works of Euclid, Pappus and Proclus mention the following: *Introductio Harmonica*, *Sectio Canonis*, relating to music; *Phænomena*, containing an exposition of the appearances produced by the motion attributed to the celestial sphere, a work subjoined to the book *De Sphæra Mobili* of Autolycus; *Optica*, *Catoptrica*, concerning direct vision and mirrors; *Liber de Divisionibus*, treating of the divisions of polygons; and the lost works, entitled *Porismatum libri*, *Locorum ad superficiem libri*, *Fallaciarum liber*, and *Conicorum libri*. At the end of the works of Euclid is a short fragment, entitled *De Levi et Ponderoso*, the author of which is unknown; it is, however, of almost no value. The editions of the works of this geometer are so numerous that we cannot undertake to indicate all of them, and must therefore confine ourselves to the principal ones. Of the complete works there are, 1. *Euclidis Opera, Græce, cum Theonis expositione, cura Grynæi*, Bâle, 1530, in fol.; 2. *Euclidis quæ supersunt omnia, ex recensione Davidis Gregorii, Græce et Latine*, Oxford, 1703, in fol.; 3. *Les Œuvres d'Euclide, en Grec, en Latin, et en Français, d'après un Manuscrit très ancien, qui était resté inconnu jusqu'à nos jours*, par Peyrard, Paris, 1814, in 8vo. The manuscript here referred to was one of several sent from Rome by Monge, and supposed to date from the end of the ninth century; in it the *Data* are placed immediately after the thirteenth book, and thus separate from the rest of the work the fourteenth and fifteenth books, which are ascribed to Hypsicles. In 1533, Hervage published at Bâle, in folio, a complete edition of the *Elements*, in the Greek text, with the exposition of Theon, and the Commentaries of Proclus on the first book. The following are the principal Latin translations: 1. *Præclarissimum Opus Elementorum Euclidis perspicacissimi in artem Geometriæ*, the first publication of the *Elements* by means of printing, Venice, 1482; 2. *Euclidis Elementorum libri XV. una cum scholiis antiquis, a Frederico Commandino Urbinate in Latinum conversi, Commentariis quibusdam illustrati*, Pesaro, 1572, in fol.; 3. *Euclidis Elementorum libri XV. demonstrationibus accuratisque scholiis illustrati, auctore Christophoro Clavio*, 1574, in 8vo; 4. *Euclidis Elementorum libri XV. breviter demonstrati, opera I. Barrow*, London, 1678, in 8vo; 5. *Elementorum Euclidis libri XV. ad Græci contextûs fidem recensiti et ad usum tyronum accommodati, edente Baermann*, Leipsic, 1769, in 8vo; 6. *Euclide Megarense philosopho, solo introduttore delle scientie mathèmatiche diligentemente reassettato per Nicolo Tartaleo Brisciano.* This last, however, is rather a paraphrase than a translation. The following are editions which only contain part of the *Elements*: 1. *Analysis Geometrica sex librorum Euclidis a Christiano Herlino, una cum commentariis et scholiis perbrevibus in eosdem libros a Cunrado Dasypodio*, 1566, in fol.; 2. *Euclidis Elementorum libri priores sex, item undecimus et duodecimus*, Oxford, 1747, in 8vo; 3. *Euclidis Elementorum libri priores sex, etc. sublatis iis quibus olim hi libri a Theone aliisve vitiati sunt, et quibusdam demonstrationibus restitutis a Roberto Simson*, Glasgow, 1756, in 4to; 4. *Eléments de la Géométrie d'Euclide, ou les six premiers livres d'Euclide, avec le XI*^{e} *et le XII*^{e}, *traduction nouvelle par Frédéric Castillon*, Berlin, 1775, in 8vo. The other works of Euclid, printed separately, are, 1. *Euclidis Data, Claudius Hardy Græce nunc primum edidit, Latine vertit, scholiis illustravit; adjectus est Marini philosophi Commentarius, Græce et Latine*, Paris, 1625, in 4to; 2. *Euclidis Rudimenta Musices, Græce et Latine excusa, J. Pena interprete*, Paris, 1557, in 4to; 3. *Euclidis Introductio Harmonica, Græce etc. Meibomius vertit ac notis explicavit* in the *Antiqui Musicæ Auctores, VII.* Amsterdam, 1652, in 4to; 4. *Optica et Catoptrica, Græce et Latine reddita, per Jo. Penam*, Paris, 1557, in 4to. For further details see Murhard, *Bibliotheca Mathematica* (tom. ii. pp. 1–48), and other similar works. We have not thought it necessary to notice the more recent editions of the *Elements*, which are in the hands of every body. (A.)

EUDIOMETER, an instrument for ascertaining the purity of the atmospherical air, or the quantity of oxygen contained in it, chiefly by means of its diminution, or the absorption produced by exposing certain substances to its action.

EUDOSIA, called ATHENIA before her conversion to Christianity, a celebrated lady, the daughter of Leontius, a philosopher of Athens, who gave her such a learned education that at his death he left her only a small legacy, saying she was capable of making her own fortune. Having pleaded at Athens without success against her two brothers for a share in her father's estate, she carried her cause personally by appeal to Constantinople, recommended herself to Pulcheria, the sister of the emperor Theodosius the Younger, embraced Christianity, was baptized by the name of *Eudosia*, and soon afterwards married to the emperor. This union lasted a considerable time; but a difference having at length taken place, on account of the emperor's jealousy, excited by Chrysapius the eunuch, Eu-

Eug

Eugene.

dosia retired to Jerusalem, where she spent many years in building and adorning churches, and in relieving the poor. Dupin says that she did not return thence till after the emperor's death; but Cave states that she was reconciled to him, returned to Constantinople, and continued with him till his death, after which she again retired to Palestine, where she spent the remainder of her life in pious works. According to Dupin, she died in the year 460; according to Cave, in 459. The latter observes that on her deathbed she took a solemn oath, by which she declared herself entirely free from any stains of unchastity. She was the author of a paraphrase in heroic verse on the first eight books of the Old Testament, and of a great number of poems, which are no longer extant.

EUDOXIANS, a party or sect of heretics in the fourth century, so denominated from their leader, Eudoxius, patriarch of Antioch and Constantinople, who was a great defender of the Arian doctrine. The Eudoxians adhered to the errors of the Arians and Eunomians, maintaining that the Son was created out of nothing, and that he had a will distinct and different from that of the Father.

EUGENE, François, commonly called Prince Eugene of Savoy, one of the greatest generals of his time (since he preceded Frederic II., and Turenne had fallen before he became known as a commander), was born at Paris on the 18th October 1663. His father, Eugene Maurice, count of Soissons, was grandson of the Duke of Savoy, Charles Emmanuel I.; and his mother, Olympia Mancini, was niece of Cardinal Mazarin; but the latter having been implicated in the affair of the poisonings, was forced to take refuge in Brussels in order to avoid prosecution. Originally destined for the church, Eugene evinced but little taste for theology, and occupied himself much more in reading the lives of great warriors, and the narratives of their exploits, than in studying the works of the fathers. Nevertheless he was of a feeble constitution; and as he wore a dark cloak, he was known at court hy the name of the Little Abbé. Louis XIV. refused him a company in a regiment of cavalry, because, according to some, he thought the young prince unfit for the profession of arms, whilst, according to others, this refusal was owing to the disgrace of his mother, and the hatred which Louvois bore to her. But however this may be, Eugene was so stung by the refusal, that, from the moment of his repulse, he conceived for the king and his minister that long and fatal resentment which at length caused so many evils to France.[1] Having quitted France in disgust, he proceeded to Vienna, where the Emperor Leopold, who was allied to his family, received him kindly, and granted him permission, along with several other Frenchmen of distinction, to serve against the Turks under the banners of Austria. His first campaign was that of 1683, during which his courage appeared so conspicuous that the emperor, by way of recompense, gave him a regiment of dragoons. After several other campaigns made with equal distinction, at the head of the same regiment, he became major-general; and it was in this capacity hat he served at the siege of Belgrade in 1688. At the nstigation of Louvois, a decree of banishment from France was now issued against all Frenchmen who should continue o serve in foreign armies. "I shall return into France in spite of him," said Eugene, when the news were communicated to him; and he continued to pursue with the same ardour the career on which he had entered in so brilliant a manner. In his case genius was stimulated by resentment.

Leopold, considering him as not less fitted for diplomacy than for war, sent Eugene as his envoy or negotiator to the Duke of Savoy, in order, if possible, to detach that prince from his connection with France. Nor did the result disappoint the expectations of the emperor. Overcome by the pressing solicitations of his young cousin, the duke allowed himself to be drawn so precipitately into the coalition against France, that, without waiting for the succours which the court of Vienna had promised him, he imprudently gave battle to Catinat at Staffarde, and was defeated, notwithstanding the great courage which Prince Eugene there displayed at the head of a corps of cavalry. But the auxiliary force sent by Austria having at length arrived, Eugene assumed the command, and, after obtaining some advantages, which placed the Duke of Savoy in a condition to defend himself, he returned to Vienna, where he decided the emperor to send fresh reinforcements. The imperial forces were thus put in a condition to resume the offensive; and Prince Eugene having arrived to command them in the spring of 1691, he caused the siege of Coni to be raised, took possession of Carmagnole, and gloriously terminated the struggle in which he had found himself engaged with Catinat. It was, in fact, as much by his successes, as by the ascendency which his superior mind exercised over the Duke of Savoy, that he managed to retain that prince in the coalition, from which he was oftener than once on the eve of breaking off, in order to throw himself again into the arms of France. Desirous to attach him still more to its interests, however, the court of Vienna conferred upon him the title of generalissimo of its forces; and it was in this capacity that he penetrated into Dauphiné at the head of ten thousand men, having Prince Eugene as his lieutenant. The combined army took possession of Embrun and Gap; laid the whole country in ashes, by way of reprisals for the burning of the Palatinate; and was preparing to carry its ravages even into Provence and Languedoc, when the generalissimo having been seized with the small-pox, this accident saved the French provinces from further devastation. Prince Eugene led the army back into Piedmont, and it was there that he received the brevet of field-marshal. After a third campaign of little importance, the Duke of Savoy having again joined the French, and thus turned the balance against the Austrians, Prince Eugene returned to Vienna, where he was appointed to the command of the army of Hungary.

It was about this time that Louis XIV. secretly offered him the baton of a marshal of France, with the government of Champagne, which his father had held, and also a pension of two thousand pistoles. But Eugene rejected these offers with indignation, and proceeded to combat the Turks commanded by the grand signior Kara-Mustapha in person. After some able marches and skilful manœuvres, he surprised the enemy at Zenta, on the Teisse, in a camp retrenched *en tête-de-pont;* and, after an attack as vigorous as it was daring, he killed twenty thousand of them, drove ten thousand into the river, made prisoners of the remainder, and took the whole of their artillery and equipages. Never had a more complete and decisive victory been obtained by the imperial arms. But this splendid achievement, at the same time that it fixed upon Prince Eugene the eyes of all Europe, inflamed to the last degree the jealousy of his rivals, or rather enemies, of whom he had many at court, some of them not less powerful than vindictive. By means of their intrigues, these persons had caused an order to be sent the prince, commanding him to suspend all attack; and this order had reached him an instant before the battle commenced, but without changing his determination to assault the enemy's position; the opportunity for striking a blow was propitious, and he boldly resolved to profit by it. This act of disobedience to the orders of the sovereign was doubtless a fault, and he who dared to commit it would have been ruined without resource had he not triumphed in a manner the most complete and decisive. But was not such a fault gloriously effaced by a victory as useful as it was brilliant? So at least thought all the world, excepting the enemies of Prince Eugene, who succeeded in persuading the emperor that nothing could excuse his disobedience; and, accordingly, when the victorious general appeared before his master, under the impression no doubt that he was to be greeted with acknowledgments and felicitations, he met with a cold and severe reception. Nor did the folly and ingratitude of his enemies stop here. Next day he was placed under arrest, and ordered to deliver up his sword; and he was about to be brought before a council of war, when the inhabitants of Vienna interposed, loudly remonstrating against the injustice of such treatment. The emperor also, whether from fear or repentance, relented, and restored his command to Prince Eugene, who, however, accepted it only on the condition that he should have *carte blanche.* It is alleged that when the envoy of the emperor came to demand his sword, he replied, "There it is, still reeking with the blood of the enemy; I consent not to resume it except for the advantage of his majesty's service." But it is now proved that this pretended reply is spurious; for, as the Prince de Ligne well observes, "one half of the phrase would have been a gasconade, and the other a meanness," neither of which comported with the simple and manly character of this great warrior. Prince Eugene then returned to Hungary; and, after a campaign distinguished by no remarkable event, a treaty of peace was at length concluded with the Turks at Carlowitz, on the 26th January 1699.

---

[1] "Quelques historiens, bons ou mauvais, se donneront peut-être la peine d'entrer dans les détails de ma jeunesse, dont je ne me souviens presque plus. Ils parleront sûrement de ma mère, un peu intriguante à la vérité, chassée de la cour, exilée de Paris, et soupçonnée, je crois, de sorcellerie, par des gens qui n'étaient pas de grands sorciers. Ils diront comment je suis né en France, et comment j'en suis sorti, la rage dans le cœur contre Louis XIV., qui m'a refusé une compagnie de cavalerie, parce que, disait-il, avais une complexion trop faible; et une abbaye, parce qu'il prétendait (sur je ne sais quels mauvais propos sur mon compte, ou ausses anecdotes de galerie de Versailles) que j'étais plus fait pour le plaisir que pour l'église. Il n'y a de Huguenot chassé par la révocation de l'édit de Nantes, qui lui ait conservé plus de haine. Aussi, quand Louvois, apprenant mon départ, dit, *Tant mieux, il e rentra plus dans ce pays-ci*, je jurai bien de n'y rentrer que les armes à la main; j'ai tenu ma parole." (*Vie du Prince Eugene*, now nown to be the production of the Prince de Ligne.)

Having returned to Vienna, the prince applied himself to the study of the arts, and particularly of history, which had always great attractions for him. But he was not permitted long to enjoy the leisure which he seemed so desirous to improve. The war of the succession, which soon broke out, opened to him a new field of glory; and at the commencement of the year 1701, he was sent into Italy once more to oppose his old antagonist Catinat. But all the prudence of the old general failed to secure him against the bold and incessantly-renewed enterprises of his young and indefatigable rival. The latter effected, in presence of the French army, the passage of the Adige, and forced it, after sustaining several checks, to retire behind the Oglio, where a series of reverses equally unexpected and severe led to the disgrace and retirement of Catinat. The Duke of Villeroi succeeded to the command of which Catinat had been deprived, and the prince had soon reason to felicitate himself on a change which, from its first announcement, transported him with joy. The presumptuous Villeroi having ventured to attack him at Chiari, in an inexpugnable position, Eugene repulsed all his efforts without difficulty, and inflicted a severe loss on the assailants. And this first check was only the forerunner of more signal reverses; for, in a short time, Villeroi was forced to abandon the whole of the Mantuan territory, and to take refuge in Cremona, where he seems to have considered himself as secure in the midst of his staff. But, by one of the most audacious enterprises which has ever been attempted in war, this place was surprised, and, had it not been for untoward accidents, would unquestionably have been carried. By means of a stratagem, Prince Eugene penetrated into the city during the night, at the head of a numerous body; and it was only owing to circumstances which could not possibly be foreseen or provided against, and particularly to the courage and vigilance of some French officers, that he found himself at length compelled to retire, carrying along with him Villeroi as a prisoner. But this last circumstance, so far from being an advantage to the Imperialists, proved the reverse; the Duke of Vendôme replaced the captive general, and his ability soon changed the aspect of affairs. From the first moment Prince Eugene appreciated the talents of his new adversary; and, besides, being aware of the superiority of the French army, with which the king of Spain in person had just effected a junction at the head of numerous reinforcements, he confined himself to a war of observation, without important results, though fertile in most useful lessons to students of military science. This campaign was terminated by the battle of Luzara, fought on the 1st of August 1702, in which each party claimed the victory. It was one of the most sanguinary ever delivered by Prince Eugene, whose fortune it was to command in so many battles; he there lost the flower of his army, and also his best officers, including the brave Commerci, his intimate friend and most faithful companion in arms.

Both armies having entered into winter quarters, Eugene returned to Vienna, where he was appointed president of the council of war. He then set out for Hungary in order to combat the insurgents in that country; but his means proving insufficient, he effected nothing of importance. The revolt was, however, put down by the success which General Heister obtained in another quarter. Prince Eugene accordingly proceeded to Bavaria, where, in 1704, he made his first campaign along with Marlborough. Similarity of tastes, views, and talents soon established between these two great men a friendship which is rarely to be found amongst military chiefs, and which contributed more than all other causes put together to the success which the allies obtained. The first and perhaps the most important of these successes was that of Hochsett or Blenheim, gained on the 13th of August 1704, where the English and imperial troops triumphed over one of the finest armies which France had as yet sent into Germany. See MARLBOROUGH.

But since Prince Eugene had quitted Italy, Vendôme, who commanded the French army in that country, had obtained various successes. The Duke of Savoy, who had once more deserted France and joined Austria, had suffered severe losses; and the emperor having decided to send him assistance, Piedmont thus became the principal theatre of active hostilities. Having received orders to proceed thither without delay, Eugene quitted Marlborough with the most lively regret, though at the same time experiencing a secret satisfaction at the prospect of measuring himself with a rival in all respects worthy of him. Vendôme at first opposed great obstacles to the plan which the prince had formed for carrying succours into Piedmont; but after a variety of marches and countermarches, in which both commanders displayed signal ability, the two armies met at Cassano, where a murder-ous engagement ensued, and Prince Eugene received two severe wounds, which forced him to quit the field. This accident decided the fate of the battle, and for the time suspended the prince's march towards Piedmont. But although prevented from effecting a junction with the Duke of Savoy, his operations failed not to prove advantageous to that prince, since the Duke de la Feuillade, then besieging Turin, was obliged to raise the siege and march to the assistance of Vendôme, who, notwithstanding his victory at Cassano, felt apprehensive of some new and daring enterprise on the part of his antagonist. Vendôme, however, was recalled, and La Feuillade was incapable of long arresting the progress of such a commander as Eugene. After once more passing several rivers in presence of the French army, and executing one of the most skilful and daring marches he had ever performed, the latter appeared before the entrenched camp at Turin, which place the French were now besieging with an army eighty thousand strong. Prince Eugene had only thirty thousand men; but his antagonist was the Duke of Orleans, who, though full of zeal and courage, wanted sufficient experience to enable him to contend with a man justly regarded as one of the greatest warriors of his time. Besides, by a secret order of Louis XIV., who had, in fact, transferred the command to Marsin, the young prince was restricted to the execution of an ill-conceived plan, which neutralized the advantage of superior numbers, and put it in the power of the enemy to select his point of attack. With equal courage and address, Eugene profited by the misunderstanding which the exhibition of such an order could not fail to produce between the French generals; and having on the 7th September 1706 attacked the French army in its entrenchments, he gained a complete victory, which decided the fate of Italy. This brilliant achievement, the result of the most masterly combinations, and, in several respects, the prototype of the campaign of Marengo in 1800, affords one of the most remarkable examples of the difficulty of defending extensive lines even against an inferior army, massed upon one or two points. As soon as the Duke of Orleans observed the imperial army approaching, he wished to march out of the lines with the whole French army, and to deliver battle in the open field, where he could have availed himself of his great numerical superiority (eighty thousand to thirty); but he was restrained by Marsin, who, by this absurd interposition, sealed the fate of the French army, and lost Italy. In the heat of the battle, which almost immediately ensued, Eugene received a wound, and was thrown from his horse into a ditch. His fall produced a belief that he was killed, and his soldiers began to lose courage; but he soon returned to the attack, and when the soldiers saw him appear in the midst of them covered with slime and blood, issuing his orders, and watching over every thing with the most admirable sang-froid, their enthusiasm was raised to the highest pitch; and from that moment the issue of the battle was certain. As a recompense for so important services, the prince received the government of the Milanese, of which he took possession with great pomp on the 16th April 1707.

The attempt which he made against Toulon, in the course of the same year, failed completely, because the invasion of the kingdom of Naples retarded the march of the troops which were to have been employed in it, and this delay afforded Marshal de Tessé time to make good dispositions. Obliged to renounce his project, therefore, the prince repaired to Vienna, where he was received with great enthusiasm both by the people and the court. "I am very well satisfied with you," said the emperor, "excepting on one point only, which is, that you expose yourself too much." This monarch immediately dispatched Eugene to Holland, and to the different courts of Germany, in order to forward the necessary preparations for the campaign of the following year, 1708.

Early in the spring of 1708 the prince proceeded to Flanders, in order to assume the command of the forces which his diplomatic ability had been mainly instrumental in assembling. This campaign was opened by the victory of Oudenarde, to which the perfect union of Marlborough and Eugene on the one hand, and the misunderstanding between Vendôme and the Duke of Burgundy on the other, seem to have equally contributed. This prince immediately abandoned the Low Countries, and remaining in observation, made no attempt whatever to raise the siege of Lille, where Boufflers distinguished himself by a glorious defence. To the valour of the latter Eugene paid the most marked and flattering homage, at the same time loading him with all those expressions of esteem and regard with which it was then usual, in such cases, to attemper the horrors of war. Boufflers was invited by his enemies to prepare the articles of capitulation himself, and Prince Eugene wrote to him, "I subscribe to every thing beforehand, well persuaded that you will not insert any thing unworthy of yourself or of me." After this important conquest, Eugene and Marlborough proceeded to the Hague, where they were received in the most flattering manner by the public, by the states-general, and, above all, by their esteemed friend the pensionary Heinsius. Negotiations were then opened for peace, but as the conditions proposed by the allies were considered by Louis XIV. as alike degrading to himself and to France, both parties made preparations for continuing the war.

The campaign of 1709 was opened in Flanders by two hostile armies, each a hundred and fifty thousand strong. That of the French was commanded by Villars, a man of considerable talents, but of little experience, and who feared to compromise himself in opposition to such great captains as Marlborough and Eugene. He accordingly remained upon the defensive, and suffered them to take Tournay without opposition; but being desirous of succouring Mons, he was followed by the allies, who attacked him at Malplaquet on the 9th of September, in a formidable position, where he had had time to entrench himself. The attack was made with equal vigour and ability; but owing to the strength of the French position, and the tenacity with which it was maintained, the victory was purchased at the cost of twenty-five thousand men killed on the field of battle, and the Dutch infantry was almost annihilated. The battle of Malplaquet was to it what the battle of Rocroi had been to the infantry of Spain; and it never afterwards recovered from the effects of that sanguinary day. Although the allies remained masters of the field of battle, this barren advantage had been so dearly bought, that they found themselves soon afterwards out of all condition to undertake any thing. Their army accordingly went into winter-quarters, and Prince Eugene returned to Vienna, whence the emperor almost immediately dispatched him to Berlin. From the king of Prussia the prince obtained every thing which he had been instructed to require; and having thus fulfilled his mission, he returned into Flanders, where, excepting the capture of Douay, Bethune, and Aire, the campaign of 1810 presented nothing remarkable. The emperor Joseph I. having died about this time, Prince Eugene, in concert with the empress, exerted his utmost endeavours to secure the crown to the archduke, who afterwards ascended the imperial throne under the name of Charles VI.

In the year following, 1711, the changes which had occurred in the policy, or rather the caprice, of Queen Anne, brought about an approximation between England and

France, and put an end to the influence which Marlborough had hitherto possessed with that princess. When this political revolution became known, Prince Eugene immediately repaired to London, charged with a mission from the emperor, and there made strenuous efforts to re-establish the credit of his illustrious companion in arms, as well as to re-attach England to the coalition. But all arguments and persuasions, whether founded on views of interest or sentiments of honour and consistency, having proved unavailing, the emperor found himself under the necessity of making the campaign of 1712 with the aid of the Dutch alone. The defection of the English, however, did not induce Prince Eugene to abandon his favourite plan of invading France. He had long been decided to make any sacrifice to accomplish this design, the conception of which originated as much, perhaps, in resentment as in a passion for glory. He therefore resolved, at whatever cost, to penetrate into Champagne; and in order to support his operations by the possession of some important places, he began by making himself master of Quesnoy. But the Dutch having been surprised and beaten in the lines of Denain, where Prince Eugene had placed them at too great a distance to receive timely support in case of an attack, he was obliged to raise the siege of Landrecies, and to abandon the project which he had so long cherished. This was the last campaign in which Austria acted in conjunction with her allies. Abandoned first by England and then by Holland, the emperor, notwithstanding these desertions, still wished to maintain the war in Germany; but the superiority of the French army prevented Eugene from relieving either Landau or Friburg, which were successively obliged to capitulate; and seeing the empire thus laid open to the armies of France, and even the hereditary states themselves exposed to invasion, the prince counselled his master to make peace. Sensible of the prudence of this advice, the emperor immediately entrusted Eugene with full powers to negotiate a treaty; and after some interviews, in which the prince and Villars interchanged expressions of esteem and admiration, there was concluded at Rastadt, on the 6th of March 1714, a peace which had long been anxiously looked for, and of which the nations of Europe had the greatest need.

After this happy event, Prince Eugene went to enjoy at Vienna some moments of repose. The emperor continued to show him marks of the most entire confidence; and from this time adopted no resolution, either in regard to the administration of the army, or that of the interior, without consulting him. But this kind of occupation did not suit the activity of Eugene; and although he was now advanced in years, his warlike humour had lost nothing of its vivacity. Sensible of the impossibility of Austria, situated as she was, resisting France, he had done all in his power to accelerate the conclusion of peace; but, by a contrary species of reasoning, he availed himself of a petty quarrel which the Ottoman Porte had with the Venetians to determine his master to espouse the cause of the latter. The emperor, having taken this step, appointed Eugene to command the army of Hungary; and at Peterwaradin, with a force not exceeding sixty thousand men, he gained a signal victory over the Turks, who had not less than a hundred and fifty thousand men in the field. This victory made a great noise in Europe, and all the Christian powers conceived themselves bound to rejoice on account of it. The pope sent to the victorious general the consecrated rapier, which the court of Rome was accustomed to bestow upon those who had triumphed over the infidels; and this extraordinary present was put into the hands of Prince Eugene by an envoy of his holiness. But the ensuing campaign, being that of 1717, was still more remarkable, on account of the battle of Belgrade. After having remained under the walls of that city, in a situation the most difficult imaginable; after having resisted, during a month, the efforts of a numerous garrison, as well as those of a hundred and fifty thousand Turks, with an army of only forty thousand men; and after having lost nearly the half of his troops by dysentery, and the fire of the Ottoman artillery, which plunged its shot even into his own tent; Prince Eugene gained one of the most complete victories of which there is any record or tradition, and soon afterwards forced Belgrade itself to capitulate. The attack which he ordered against forces six times more numerous than his own was really an act of despair. He had himself been seized with the cruel malady which was destroying his army, and all was consternation in the Austrian camp; yet at the very moment when he was believed to be on the eve of capitulating, he succeeded, by his constancy and daring courage, in obtaining a most decisive victory. The prince was wounded in the heat of the action, this being the thirteenth time that he had been hit upon the field of battle. On his return to Vienna he received numerous testimonies of gratitude, and, amongst others, a sword valued at eighty thousand florins, which was presented to him by the emperor. In the following year, 1718, after some fruitless negotiations with a view to the conclusion of peace, he again took the field; but the treaty of Passarowitz put an end to hostilities, at the moment when the prince had well-founded hopes of obtaining still more important successes than those which had illustrated the last campaign, and when he even flattered himself with reaching Constantinople, and dictating a peace on the shores of the Bosphorus. On his return to Vienna he was, as usual, received with every mark of esteem and admiration.

As the government of the Low Countries, formerly conferred upon Eugene, had now for some reason been bestowed on a sister of the emperor, the prince was appointed vicar-general of Italy, with a pension of three hundred thousand florins. From this time he occupied himself much more than he had ever done with the affairs of government; and Charles VI. habitually consulted him in all affairs of importance. He accompanied this monarch in several journeys, particularly to Prague, where Frederick I. of Prussia met the emperor by appointment, and testified the greatest admiration of the veteran warrior, by whom the latter was attended; and his influence seemed to be in all respects commensurate with his fame. During the ten years of peace which ensued, Eugene occupied himself with the arts and with literature, to which he had hitherto been able to devote little of his time. But the contest which arose out of the succession of Augustus II. to the throne of Poland having afforded Austria a pretext for attacking France, war was resolved on, contrary to the advice of Prince Eugene, whose last campaigns had taught him to dread the efforts of that power. Yet, although he had in the council declared his opinion in favour of peace, he was appointed to command the army destined to act upon the Rhine. This army, from the commencement, had very superior forces opposed to it; and if it could not prevent the capture of Philipsburg after a long siege, it at least prevented the enemy from entering Bavaria. Prince Eugene, having now attained his seventy-first year, no longer possessed the vigour and activity necessary for the command of armies; he himself perceived the change which time had wrought in his powers; and as he now longed for and required repose, he applied himself to bring about a peace, which was at length concluded on the 3d of March 1733. Having returned to Vienna, his health declined more and more, and he died in that capital on the 21st April 1736, leaving an immense succession to his niece the Princess Victoria of Savoy.

Of a character cold and severe, Prince Eugene had almost no other passion than that of glory. He died unmarried, and without having ever evinced the slightest partiality for any woman, excepting, perhaps, the Countess de Bathiani, who, by the attractions of her wit and vivacity, appears to have consoled the last moments of his life. Although one of the greatest warriors of his time, military science is not indebted to him for any remarkable improvement. His operations were not directed according to any positive method, nor conformable to invariable principles; it was by sudden inspirations, and an admirable rapidity of *coup d'œil*, that he conducted himself on the ground according to the circumstances and the men with whom he had to deal; and upon all occasions he took the greatest pains to ascertain the character of the generals who were opposed to him. This system of tactics chiefly resembles that which we have seen displayed in the recent wars; it exhibits neither the prudence and circumspection of Turenne, nor the astonishing strategic ability of Frederick, in the difficult art of putting in motion and deploying columns and lines: it consists merely in an incessant activity and audacity, united with an admirable promptitude in perceiving and repairing faults. Despising the lives of his soldiers as much as he exposed his own, it was always by persevering efforts and great sacrifices that he obtained victory. To the Austrian armies he gave an eclat which they had never before possessed, and which, as it was reflected from his character alone, died with him; in fact, he could not sustain himself without efforts which wars so protracted and destructive rendered impossible upon the part of the people of Austria. This exhaustion, indeed, was long felt in the Austrian monarchy; and as that power has not had a single general since the time of Prince Eugene who can at all be compared with him, its armies have not subsequently been illustrated by any remarkable event, and the reputation of this general has consequently stood far above that of all other commanders in the imperial service. Prince Eugene, in truth, had a prevailing passion for war. Always on the march, in camps, or on the field of battle during more than fifty years, and under the reign of three emperors, he had scarcely passed two years together without fighting. It has been said that he loved letters and the arts; and the protection which he afforded to J. B. Rousseau has often been cited as a proof of this commendable taste. It is certain, indeed, that in his numerous expeditions, he had made an immense collection of objects interesting to science and art, as well as of valuable books and manuscripts; but it is evident that he never took time to examine them; and there is nothing to prove that he knew how to appreciate their value. He profited by war, which, in every point of view, prodigiously enriched him; and if he must be ranked with Turenne, Vendôme, and Catinat in regard to personal valour, he cannot be compared with them in point of disinterestedness and generosity. Prince Eugene was a man of the middle size, but, upon the whole, well made; the cast of his visage was somewhat ong, his mouth moderate, and almost always open; his eyes were black and animated, and his complexion such as became a warrior. His funeral oration, composed in Italian by Cardinal Passionei, was translated into French by Madame du Boccage, 1759, in 12mo. But the most complete work on his life is the *Histoire du Prince Eugène*, Amsterdam, 1740, and Vienna, 1755, which was published anonymously, though it is now known to be the compilaion of a M. de Mauvillon. It was from this production hat the Prince de Ligne derived the greater part of the writing which he published in Germany in 1809, and which was twice printed the year following at Paris, under the title of *Vie du Prince Eugène de Savoie, écrite par lui-même*, in one vol. 8vo. There exists in German a history of Prince Eugene, which is little esteemed; and there was also published at Nuremberg, in 1738, a work entitled *Eugenius nummis illustratus*, which is of little value. But the Italian work on the Life and Campaigns of Prince Eugene, published at Naples in 1754, 8vo, is much more exact. We have also *Campagnes du Prince Eugène en Hongrie*, in 2 vols. 8vo; and *Histoire Militaire du Prince Eugene, du Duc de Marlborough, et du Prince de Nassau*, 2 vols. fol. by Dumont, and continued by Rousseau, Hague, 1729. The work of Father Ferrari, entitled *De Rebus Gestis Eugenii Principis Sabaudiæ, Bello Pannonico*, is much more remarkable for the purity of the style than for the accuracy of the facts. (A.)

EUGUBIAN, or EUGUBINE TABLES, *Tabulæ Eugubinæ*, inscribed tablets in bronze, found in 1444 at La Schieggia, near Gubbio (*Eugubium*), in the duchy of Urbino. These tablets are seven in number, five of them containing inscriptions in Umbric, mixed with Etruscan, and the remaining two inscriptions in Latin characters. They were at first believed to be of very high antiquity; but it is now pretty generally agreed that they are not more ancient than the fourth century before the Christian era. The learned reader will find copies of these remarkable monuments in Dempster's *Etruria Regalis* (vol. i. p. 91, et seqq.), and also some curious details respecting them in the supplement to that work by the senator Buonarotti (vol. ii. p. 101). According to Lanzi, they refer entirely to the mode of sacrifice, the particular forms of prayer, and other religious rites of certain Umbrian communities, who were united in a sort of federal bond; but the explanations of the learned Italian are much too arbitrary and hypothetical to be of any authority; and, in point of fact, we are still as ignorant of the *language* of these inscriptions as when the tablets were first discovered, nearly four centuries ago. (See article ETRUSCANS.) But as the character has proved less untractable than the text, an Etruscan alphabet has been constructed, by means of which we are enabled to read the words which as yet we cannot interpret. Previously to the time (1732) when Bourguet undertook this difficult task, several persons had attempted it, and failed. But, by carefully comparing the tablets in the Roman character with those in the Etruscan, the ingenious Frenchman discovered that the former were a compendium of the latter, and that many words were common to both sets; and, having obtained this key, he succeeded, by pursuing the comparison he had instituted, in constructing an alphabet which, though far from being complete, was yet much more perfect than any which had preceded it. Since the time of Bourguet, however, no further progress has been made in this confined but interesting field of inquiry; and as the language has hitherto baffled every artifice of interpretation, the contents of these curious monuments of antiquity still remain undeciphered. The discovery of a bilingual inscription, which is not an impossible event, would, however, furnish the needful key, and lead directly to the solution of an enigma alike vexatious and interesting to the scholar. Should this ever happen, or should some rare effort of sagacity or miracle of fortune unexpectedly put any inquirer on the right road without such aid, we venture to prognosticate that the language of these inscriptions will be found to be radically Celtic, perhaps a dead dialect of that language, intermixed with terms of Pelasgic origin. That the Umbri were Celts, or at least of Celtic origin, there can be little doubt; and it seems equally certain that the Etruscans, who ultimately predominated over all the other tribes which from time to time had settled in

Etruria, were also, in part at least, of northern descent. It would therefore be strange indeed if in these inscriptions, five of which are in the Umbric mixed with the Etruscan character, no traces were found of that primitive language which successive immigrations from the north must have diffused over a considerable portion of the great plain of Italy. The Eugubine Tables were first published by Smetius, 1588; then by Gruter, *Inscript.* vol. i. p. 142. (Bourguet, *Dissert. Mem. Cort.* tom. i. p. 1; Dempster, *De Etruria Regali*, ubi supra; and Lanzi, *Saggio di Lingua Etrusca*. See also *Beitrage zur Deutung der Eugubinischen Tafeln* von Lassen. Bonn, 1833.) (A.)

EULER, Leonard, professor of mathematics, member of the Imperial Academy of Petersburg, ancient director of the Royal Academy of Berlin, and fellow of the Royal Society of London, as also a corresponding member of the Royal Academy of Sciences at Paris, was born at Basil on the 15th of April 1707, of reputable parents. The years of his infancy were passed in a rural retreat at the village of Richen, of which place his father was minister. Being sent to the university of Basil, he attended regularly the different professors; and as his memory was prodigious, he performed his academical tasks with uncommon rapidity; but all the time he thus gained was consecrated to geometry, which soon became his favourite study. The early progress which he made in this science only gave new ardour to his application; and thus he obtained a distinguished place in the esteem of John Bernoulli, who was at that time one of the first mathematicians in Europe, as well as in the friendship of Daniel and Nicolas Bernoulli, who were already the rivals of their illustrious father. In 1723 Euler took his degree as master of arts, and delivered on that occasion a Latin discourse, in which he drew a comparison between the philosophy of Newton and the Cartesian system, which was received with the greatest applause. At his father's desire he afterwards applied himself to the study of theology and the oriental languages, and though these studies were foreign to his predominant propensity, his success was considerable; but, with his father's consent, he returned to geometry as his principal pursuit. He continued to avail himself of the counsels and instructions of John Bernoulli; he contracted, as already stated, an intimate friendship with his two sons, Daniel and Nicolas; and it was in consequence of these connexions that he became afterwards the principal ornament of the Academy of Petersburg. The project of erecting this academy, which had been formed by Peter the Great, was executed by Catherine I.; and the two young Bernoullis being invited to Petersburg in 1725, promised Euler, who was desirous of following them, that they would use their utmost endeavours to procure for him an advantageous settlement in that city. In the mean time, by their advice, he applied himself with ardour to the study of physiology, to which he made a happy application of his mathematical knowledge; and he also attended the medical lectures of the most eminent professors of Basil. This study, however, did not wholly engross his time, nor even relax the activity of his powerful and comprehensive mind in the cultivation of other branches of natural science. For whilst he was keenly engaged in physiological researches, he composed a dissertation on the nature and propagation of sound, and an answer to a prize-question concerning the masting of ships, to which the Academy of Sciences adjudged the *accessit*, or second rank, in the year 1727. From this latter discourse, and other circumstances, it appears that Euler had early embarked in the curious and important study of navigation, which he afterwards enriched with so many valuable discoveries.

Euler's merit would have given him an easy admission to honourable preferment, either in the magistracy or university of his native city, if both civil and academical honours had not been there distributed by lot. But chance having decided against him in regard to a certain situation to which he aspired, he left his country, set out for Petersburg, and was made joint professor with his countrymen Hermann and Daniel Bernoulli in the university of that city. At the commencement of his new career he enriched the academical collection with many memoirs, which excited a noble emulation between him and the Bernoullis; and this emulation always continued, without either degenerating into a selfish jealousy, or producing the least alteration in their friendship. It was at this time that he carried to a new degree of perfection the integral calculus, invented the calculation of sines, reduced analytical operations to a greater simplicity, and threw new light on all the parts of mathematical science. In 1730 he was promoted to the professorship of natural philosophy; and in 1733 he succeeded his friend Daniel Bernoulli in the mathematical chair. In 1735 a problem was proposed by the academy which required expedition, and for the solution of which several eminent mathematicians had demanded the space of some months. The problem was solved by Euler in three days, to the great astonishment of the academy; but the violent and laborious efforts it cost him threw him into a fever, which endangered his life, and deprived him of the use of his right eye. The Academy of Sciences at Paris, which in 1738 had adjudged the prize to his memoir concerning the nature and properties of fire, proposed for the year 1740 the important subject of the tides; a problem the solution of which required the most arduous calculations, and comprehended the theory of the solar system. Euler's discourse on this question was considered as a masterpiece of analysis and geometry; and it was more honourable for him to share the academical prize with such illustrious competitors as Colin Maclaurin and Daniel Bernoulli, than to have carried it away from rivals of inferior reputation. Rarely if ever did such a brilliant competition adorn the annals of the academy; and no subject, perhaps, proposed by that learned body, was ever treated with such accuracy of investigation and force of genius, as that which here displayed the philosophical powers of these three extraordinary men.

In the year 1741 Euler was invited to Berlin in order to augment the lustre of the academy which was there rising into fame. He enriched the last volume of the *Mélanges* or Miscellanies of Berlin with five memoirs, which make an eminent, perhaps the principal, figure in that collection; and these were followed, with an astonishing rapidity, by a great number of important researches, which are scattered throughout the memoirs of the Prussian academy, of which a volume was regularly published every year. The labours of Euler will appear more astonishing when it is considered, that whilst he was enriching the Academy of Berlin with a prodigious number of memoirs on the deepest parts of mathematical science, containing always some new views, often sublime truths, and sometimes discoveries of great importance, he did not discontinue his philosophical contributions to the Academy of Petersburg, which granted him a pension in 1742, and the memoirs of which display the marvellous fecundity of Euler's genius. It was with much difficulty that this great man obtained, in 1766, permission from the king of Prussia to return to Petersburg, where he desired to pass the remainder of his days. Soon after his return, which was graciously rewarded by the munificence of Catherine II., he was seized with a violent disorder, which terminated in the total loss of his sight. A cataract, having formed in his left eye, which had been essentially

Euler.

damaged by a too ardent application to study, deprived him entirely of the use of that organ. It was in this distressing situation that he dictated to his servant, a tailor's apprentice, who was absolutely devoid of mathematical knowledge, his *Elements of Algebra;* which, by their intrinsical merit in point of perspicuity and method, and the unhappy circumstances in which they were composed, have excited equal applause and astonishment. This work, though purely elementary, discovers the characteristics of an inventive genius; and it is here alone that we meet with a complete theory of the analysis of Diophantus.

About this time Euler was honoured by the Academy of Sciences at Paris with the place of foreign member of that learned body; and after this, the academical prize was adjudged to three of his memoirs, *Concerning the Inequalities in the Motions of the Planets.* The two prize-questions proposed by the same academy for 1770 and 1772 were designed to obtain from the labours of astronomers a more perfect theory of the moon. Euler, assisted by his eldest son, was a competitor for these prizes, and obtained both. In this last memoir he reserved for further consideration several inequalities of the moon's motion, which he could not determine in his first theory, on account of the complicated calculations in which the method he then employed had engaged him. But he had the courage afterwards to review his whole theory, with the assistance of his son and Messrs Krafft and Lexell, and to pursue his researches until he had constructed the new tables, which appeared, together with the great work, in 1772. Instead of confining himself, as before, to the fruitless integration of three differential equations of the second degree, which are furnished by mathematical principles, he reduced them to the three ordinates, which determine the place of the moon; and he divided into classes all the inequalities of that planet, as far as they depend either on the elongation of the sun and moon, or upon the eccentricity, or the parallax, or the inclination of the lunar orbit. All these means of investigation, employed with such art and dexterity as could only be expected from analytical genius of the first order, were attended with the greatest success; and it is impossible to observe without admiration such immense calculations on the one hand, and on the other the ingenious methods employed by this great man to abridge them, and to facilitate their application to the real motion of the moon. But this admiration will become astonishment when we consider at what period and in what circumstances all this was effected. It was when he was totally blind, and consequently obliged to arrange all his computations by the sole powers of his memory and his genius; when he was embarrassed in his domestic circumstances by a dreadful fire, which had consumed the greater part of his substance, and forced him to quit a ruined house, every corner of which was known to him by a habit that in some measure supplied the place of sight;—it was in these circumstances, and under these privations, that Euler composed a work, which alone is sufficient to render his name immortal. The heroic patience and tranquillity of mind which he displayed need no eulogy here; and he derived them not only from the love of science, but from the power of religion. His philosophy was too genuine and sublime to stop its analysis at mechanical causes; it led him to that divine philosophy of religion which ennobles human nature, and is alone capable of forming a habit of true magnanimity and patience under suffering.

Some time after this the celebrated Wenzell, by couching the cataract, restored Euler's sight; but the satisfaction and joy which this successful operation produced were of short duration. Some instances of negligence on the part of his surgeons, and his own impatience to use an organ the cure of which was not complete, deprived him of vision a second time; and this relapse was accompanied with tormenting pain. With the assistance of his sons, and of Messrs Krafft and Lexell, however, he continued his labours; neither the loss of his sight nor the infirmities of an advanced age being sufficient to damp the ardour of his genius. Having engaged to furnish the Academy of Petersburg with as many memoirs as would be sufficient to complete its acts for twenty years after his death, he in the space of seven years transmitted to the academy above seventy memoirs, and left above two hundred more, which were revised and completed by the author of this notice. Such of the memoirs as were of ancient date were separated from the rest, and form a collection which was published in the year 1783, under the title of *Analytical Works.*

Euler's knowledge was more universal than could well be expected in one who had pursued with such unremitting ardour mathematics and astronomy as his favourite studies. He had made very considerable progress in medical, botanical, and chemical science; he was an excellent scholar, and possessed what is generally called erudition in a very high degree. He had read, with attention and taste, the most eminent writers of ancient Rome; the civil and literary history of all ages and all nations was familiar to him; and foreigners who were only acquainted with his works were astonished to find in the conversation of a man whose long life seemed to have been wholly occupied in mathematical and physical researches and discoveries, such an extensive acquaintance with the most interesting branches of literature. In this respect, no doubt, he was much indebted to an uncommon memory, which seemed to retain every idea that was conveyed to it, either from reading or meditation. He could repeat the Æneid of Virgil from the beginning to the end without hesitation, and indicate the first and last line of every page of the edition which he used.

But several attacks of vertigo, in the beginning of September 1783, which did not prevent his calculating the motions of the aerostatical globes, proved the forerunners of his mild and happy passage from this scene to a better. His death was sudden; he ceased to calculate and to live at nearly the same instant of time. Whilst he was amusing himself at tea with one of his grandchildren, he was struck with apoplexy, which terminated his illustrious career at the age of seventy-six. Euler, says Condorcet, was one of those men whose genius was equally capable of the greatest efforts and of the most continued labour; who multiplied his productions beyond what might have been expected from human strength, and who notwithstanding was original in each; whose head was always occupied, and his mind always calm. The nature of his pursuits, by withdrawing him from the world, preserved that simplicity of manners for which he was originally indebted to his character and his education; and he employed none of those means to which men of real merit have sometimes recourse in order to enhance the importance of their discoveries. It is true that fecundity such as his renders useless all the little calculations of self-love; but still great lucidity of mind and uprightness of character are necessary to trace, as he has done, the history of his thoughts, even when his investigations have proved fruitless, or the results disappointed the expectations which he had formed. Euler's constitution was uncommonly vigorous; his health was good; and the evening of his long life was serene, being sweetened by the fame which follows genius, the public esteem and respect which are never withheld from exemplary virtue, and several domestic comforts, which he was capable of feeling, and therefore deserved to enjoy.

The works which Euler published separately are, 1. *Dissertatio physica de Sono*, Bâle, 1727, in 4to; 2. *Mechanica, sive Motûs scientia, analytice exposita*, Petersburg, 1736, in 2 vols. 4to; 3. *Einleitung in die Arithmetik*, or Introduction to Arithmetic, ibid. 1738, 2 vols. 8vo, in German and Russian; 4. *Tentamen Novæ Theoriæ Musicæ*, ibid. 1739, in 4to; 5. *Methodus inveniendi Lineas curvas, maximi minimive proprietate gaudentes, sive solutio problematica isoperimetrici latissimo sensu accepti*, Lausanne, 1744, in 4to; 6. *Theoria motuum Planetarum et Cometarum, continens methodum facilem ex aliquot observationibus orbitas*, etc. *determinandi*, Berlin, 1744, in 4to; 7. *Beantwortung*, etc. or Answers to different Questions respecting Comets, ibid. 1744, in 8vo; 8. *Neue Grundsætze*, etc. or New Principles of Artillery, translated from the English of Benjamin Robins, with notes and illustrations, ibid. 1745, in 8vo; 9. *Opuscula varii argumenti*, ibid. 1746–1751, in 3 vols. 4to; 10. *Novæ et correctæ Tabulæ ad loca Lunæ computanda*, ibid. 1746, in 4to; 11. *Tabulæ Astronomicæ Solis et Lunæ*, ibid. 4to; 12. *Gedanken*, etc. or Thoughts on the Elements of Bodies, ibid. 4to; 13. *Rettung der Gottlichen Offenbarung*, etc. Defence of Divine Revelation against Freethinkers, ibid. 1747, in 4to; 14. *Introductio in Analysin Infinitorum*, Lausanne, 1748, in 2 vols. 4to; 15. *Scientia Navalis, seu Tractatus de construendis ac dirigendis Navibus*, Petersburg, 1749, in 2 vols. 4to; 16. *Theoria motûs Lunæ*, Berlin, 1753, in 4to; 17. *Dissertatio de principio minimæ actionis, una cum examine Objectionum cl. prof. Kœnigii*, ibid. 1753, in 8vo; 18. *Institutiones Calculi Differentialis, cum ejus usu in analysi Infinitorum ac doctrina Serierum*, ibid. 1755, in 4to; 19. *Constructio Lentium Objectivarum*, etc. Petersburg, 1762, in 4to; 20. *Theoria motûs Corporum solidorum seu rigidorum*, Rostoch, 1765, in 4to; 21. *Institutiones Calculi Integralis*, Petersburg, 1768–1770, in 3 vols. 4to; 22. *Lettres à une Princesse d'Allemagne sur quelques sujets de Physique et Philosophie*, Petersburg, 1768–1772, in 3 vols. 8vo; 23. *Anleitung zur Algebra*, or Introduction to Algebra, Petersburg, 1770, in 8vo; 24. *Dioptrica*, Petersburg, 1767–1771, in 3 vols. 4to; 25. *Theoria motuum Lunæ nova methodo pertractata*, ibid. 1772, in 4to; 26. *Novæ Tabulæ Lunares*, ibid. in 8vo; 27. *Théorie complète de la construction et de la manœuvre des Vaisseaux*, ibid. 1773, in 8vo; 28. *Eclaircissements sur les établissements en faveur tant des Veuves que des Morts*, without a date; 29. *Opuscula Analytica*, Petersburg, 1783–1785, in 2 vols. 4to.

EULOGY, Eulogia, in *Ecclesiastical History*. When the Greeks cut a loaf or piece of bread to consecrate it, they broke the rest into little bits, and distributed it among the persons who had not yet communicated, or sent it to persons who were absent; and these pieces of bread were what they called *eulogies*. The word is Greek, *ευλογια*, formed from ευ, *bene*, well, and λεγω, *dico*, I say or speak; meaning *benedictum*, or blessed. The Latin church, for a great many ages, had something like eulogies; and thence arose the use of the holy bread. The name *eulogy* was likewise given to loaves or cakes brought to church by the faithful to have them blessed. Lastly, the use of the term passed hence to mere presents made to a person without any benediction.

Eulogy likewise means an encomium pronounced on any person by reason of some virtue or good quality.

EUMARIDES, from ευμαρης, *easy* or *convenient*, among the ancients, a kind of shoes common to men and women. The eumarides were used for pomp and delicacy, being neat, and painted with various colours.

EUMENES, a native of Cardia, a city in the Thracian Chersonesus, was born 360 and died 315 B. C. At a very early age he was employed as private secretary by Philip king of Macedonia, on account of his friendship for his father. On the death of that prince he was confirmed in the same office by Alexander; and it was in this capacity that he accompanied that monarch into Asia. So highly did Alexander esteem him that he gave him in marriage a Persian lady of noble birth, sister to her who had married Ptolemy. Upon the death of Alexander, the provinces and armies were divided amongst his generals, and the countries assigned to Eumenes were Cappadocia and Paphlagonia, with the sea-coast of Pontus as far as Trapezus; but as they were not yet subdued, Leonatus and Antigonus were commissioned to put him in possession. Antigonus disregarded the orders of Perdiccas, and Leonatus having in vain attempted to induce Eumenes to accompany him to the assistance of Antipater in Europe, made an unsuccessful attack on his life. Eumenes escaped and joined Perdiccas, who assisted him in taking possession of Cappadocia.

About this time Craterus and Antipater, having reduced Greece, determined to pass into Asia and overthrow the power of Perdiccas. It may be easily imagined that Cappadocia was the first object of their attack; and accordingly Eumenes was appointed commander of all the forces in the neighbouring countries. But to this Neoptolemus, one of the generals, refused to submit; and being defeated by Eumenes, he fled to Antipater and Craterus. The presence of Antipater was required in Cilicia, and the army destined to act against Eumenes was therefore commanded by Craterus and Neoptolemus. They were, however, completely defeated; Neoptolemus was killed, and Craterus died of his wounds, 321 B.C. The pride of the Macedonians was hurt by this defeat of two of their generals by a person whom they considered as a stranger; and the news having reached them a few days after the death of Perdiccas, the Macedonian chiefs condemned Eumenes to death, and charged Antipater and Antigonus with the execution of their order. Eumenes was at first successful, but being defeated through the treachery of one of his officers, he fled to Nora, a strong fortress on the confines of Cappadocia and Lycaonia. Here he made a successful resistance, and was afterwards appointed by Olympias to command the army against Antigonus, whose intentions could no longer be misunderstood. He gained a battle against his adversary, but was unlucky enough to lose the baggage and wives belonging to his Macedonian phalanx. Antigonus offered to restore them on condition that the soldiers would surrender Eumenes into his hands, which they were base enough to agree to; and Antigonus immediately murdered his opponent, in the fortieth year of his age. (Plutarch, *Life of Eumenes*; Nepos; Diodor. Sic. xviii. 30.

Eumenes I. a king of Pergamus, succeeded his uncle Philotærus 263 B. C., and having engaged in hostilities with Antiochus, king of Syria, defeated him near Sardes. But he fell a victim to his habits of drunkenness 241 B. C. and was succeeded by his cousin Attalus. (Strabo, xiii. 624; Athenæus, x. p. 445.)

Eumenes II. eldest son of Attalus I. succeeded to the government of Pergamus on his father's death, 197 B. C., and continued to maintain the intimate alliance which it had been his father's policy to form with the Romans. Antiochus the Great, king of Syria, who at that time secretly meditated contesting the supremacy of the Romans, tried to seduce him by offering one of his daughters in marriage; but Eumenes suspecting the interested intentions of Antiochus, prudently refused the honour of this alliance. In the war which soon afterwards broke out he proved himself the firm friend of the Romans, and assisted Livius Salinator in his victory over the fleet of Antiochus (191 B. C.), on which occasion he was greatly distinguished for his bravery. Again, in the decisive battle which was fought at the foot of Mount Sipylus, in which Antiochus was completely defeated (188 B. C.), the troops of Eumenes greatly distinguished themselves; and on the conclusion of peace this prince received a great addition to his territories at the expense of Antiochus. He was afterwards attacked by Prusias, king of Bithynia, whose forces were under the command of the celebrated Hannibal, and by Pharnaces, king of Pontus; but the powerful mediation of the Romans compelled all parties to lay down their arms. Having become acquainted with the designs of Perseus against the Romans, Eumenes set out for Rome (172 B. C.), to warn the senate of the preparations for war which were making against them. On his return he wished to offer sacrifices to Apollo at Delphi, when he was attacked by a party of assassins stationed by Perseus, and narrowly escaped with his life. He was then carried by his friends to the island of Ægina, where he remained in concealment for some time. A report of his death having reached his brother, the latter assumed the reins of government, and married Stratonice the wife of Eumenes. When he reappeared, this proceeding does not seem to have changed his conduct towards his brother; and they lived in the same amity as before. His close intimacy with the Romans seems to have been broken off towards the end of his reign, and that people endeavoured to embroil him with the neighbouring princes. In this embarrassing state of affairs he died 157 B. C. leaving his throne to his brother Attalus II. (See Sevin, *Recherches sur les Rois de Pergame*, in the *Mémoires de l'Acad. des Inscr.* xii. p. 260.)

Eumenes, a celebrated orator of Athens about the beginning of the fourth century, some of whose harangues and orations are still extant. Also an historical writer in Alexander's army.

EUMENIDES, a name given to the Furies by the ancients. They are fabled to have sprung from the blood of the wound which Cœlus received from his son Saturn; but according to others they were daughters of Earth, and conceived from the blood of Saturn; whilst others again make them daughters of Acheron and Night, or of Pluto and Proserpine. They were three in number, Tisiphone, Megara, and Alecto, to whom some add Nemesis. Plutarch mentions only one called Adrasta, the daughter of Jupiter and Necessity. Supposed to be the ministers of the vengeance of the gods, they were stern and inexorable, and were always employed in punishing the guilty upon earth, as well as in the infernal regions. Upon earth they inflicted the divine vengeance by means of wars, pestilence, and dissensions, and by the secret stings of conscience; in hell they punished the guilty by continual flagellation and torments. They were also called *Furiæ* and *Erinnys.* Their worship was almost universal, and people dared not to mention their names or to look upon their temples. They were honoured with sacrifices and libations; and in Achaia they had a temple, which, when entered by any one guilty of a crime, suddenly deprived him of the use of his reason, and rendered him furious. In sacrifices their votaries used branches of cedar and of alder, hawthorn, saffron, and juniper; and the victims were generally turtle doves and sheep, together with libations of wine and honey. They were usually represented as of grim and frightful aspect, with black and bloody garments, and serpents wreathed round their heads instead of hair. They held a burning torch in one hand, and a whip of scorpions in the other; and were always attended by Terror, Rage, Paleness, and Death. In hell they were seated around Pluto's throne, as the appropriate ministers of his vengeance.

EUMENIDIA, festivals in honour of the Eumenides, called by the Athenians σεμναι θεαι, or venerable goddesses, which were celebrated once every year, with sacrifices of pregnant ewes, offerings of cakes made by the most eminent youths, and libations of honey and wine. At Athens none were admitted but freeborn citizens who had led a life the most virtuous and unsullied.

EUMOLPIDES, the priests of Ceres at the celebration of her festivals at Eleusis. They were descended from Eumolpus, a king of Thrace, who was appointed priest of Ceres by Erechtheus, king of Athens. After his appointment to the priesthood, however, Eumolpus became so powerful that he maintained a war against Erechtheus. The contest proved fatal to both; Erechtheus and Eumolpus were killed; and peace was re-established amongst their descendants, on condition that the priesthood should for ever remain in the house of Eumolpus, and the regal power in that of Erechtheus. The priesthood remained in the family of Eumolpus for twelve hundred years; and this is the more remarkable, because he who was once appointed to the holy office was obliged to observe perpetual celibacy.

EUNAPIUS, a native of Sardis, in Lydia, a celebrated sophist, physician, and historian, who flourished in the fourth century, under the emperors Valentinian, Valens, and Gratian. He wrote the lives of the philosophers and sophists, in which he frequently shows himself a bitter enemy to the Christians; and also a history of the Cæsars, which he brought down from the reign of Claudius, where Herodian ended, to that of Arcadius and Honorius. The history is lost; but its substance has been preserved in Zosimus, who is supposed to have done little more than copy it.

EUNOMIANS, in *Ecclesiastical History*, Christian heretics in the fourth century. They were a branch of the Arians, and took their name from Eunomius, bishop of Cyzicus, who died at a very advanced age, about the year 374, after experiencing a variety of sufferings. The greater part of his works are lost. Besides two or three small pieces, however, there remains a confession of his faith, which Cave has inserted in his *Historia Literaria*, from a manuscript in Archbishop Tennison's library.

EUNUCH, a castrated or emasculated person. Though the practice of castration is detestable in every point of view, yet there appears no real foundation for the injurious opinion generally entertained of eunuchs, that they are all cowards, and devoid of genius for literature or any solid study. It is certain, indeed, that the ancients never supposed eunuchs to be men of inferior intellects, or that they possessed less vigour of mind than other men. It appears from Herodotus that in Persia eunuchs were far from being objects of contempt, and were even frequently promoted to the highest honours. We learn from Agathias, one of the Byzantine historians, that a general in the Roman army named Narses was an eunuch. Aristotle paid such high respect to Hermias, who was an eunuch, and governor of Atarnea, in Mysia, that he even offered sacrifices in honour of him, as Lucian informs us in the dialogue entitled *Eunuchus.*

Eunuchs, in *Ecclesiastical History*, a sect of heretics in the third century, who were mad enough to castrate not only those of their own persuasion, but all others whom they could lay hold of.

EUPATRIDÆ, in *Antiquity*, a name given by Theseus to the nobility of Athens, as distinguished from the Geomori and Demiurgi. By the establishment of Theseus, the Eupatridæ had the right of choosing magistrates, teaching and dispensing the laws, and interpreting religious mysteries. In all other matters the whole city was reduced to an equality. The Geomori were husbandmen, and inferior to the Eupatridæ in point of fortune; the Demiurgi were artificers, and fell short of the Eupatridæ in number.

Eupen
||
Euphrates.

EUPEN, a city of the Prussian province of the Lower Rhine, the capital of a circle of the same name. It is a large scattered place, containing 1500 houses, and between 10,000 and 11,000 inhabitants, who carry on the manufacture of fine woollen cloths and cassimeres to an extent which is unknown in any other part of the same kingdom.

EUPHONY, in *Grammar*, an easiness, smoothness, and elegance of pronunciation. The word is formed from ευ, *bene*, well; and φωνη, *vox*, voice. Quintilian calls *euphonia, vocalitas;* Scaliger, *facilis pronunciatio.*

Euphonia is properly a kind of figure by which we suppress a letter that is too harsh, or convert it into a smoother, contrary to the ordinary rules. Of these there are numerous examples in all languages.

EUPHORBUS, a famous Trojan, son of Panthöus. He was the first who wounded Patroclus, whom Hector killed; but he perished by the hand of Menelaus, who hung his shield in the temple of Juno at Argos. Pythagoras, the founder of the doctrine of the metempsychosis, or transmigration of souls, affirmed that he had once been Euphorbus, and that his soul recollected many exploits which had been done whilst it animated the body of that redoubted Trojan. As a further proof of his assertion, he showed at first sight the shield of Euphorbus in the temple of Juno.

EUPHORION, a son of Polymnestus of Chalcis, a town of Eubœa, born 274 B. C. at the time when the Romans conquered Pyrrhus. He studied under the philosophers Lacydes and Prytanis, and composed many works both in prose and verse. He was appointed by Antiochus the Great, king of Syria, to superintend the library he was collecting at Antioch, which he was anxious should rival that at Alexandria; and here Euphorion resided till his death. Only a few fragments of his works have been preserved; but from the opinions expressed by ancient writers we find that the erudite character of his allusions rendered him so obscure that he was difficult to be understood, and that he was constantly in search of rare and obsolete expressions. Yet he was much admired in the time of Cicero; and in the reign of Augustus his works still continued to be favourites. Cornelius Gallus translated some of his poems; but it was the Emperor Tiberius who carried his admiration beyond all bounds. He imitated his style, as well as that of Rhiarius and Parthenius, and placed their books and busts in all the public libraries. See an account of his life and character by Meinecke, prefixed to an edition of his fragments; *De Euphorionis Chalcidensis Vita et Scriptis*, &c. Gedani, 1823; also Clinton's *Fasti Hellenici*, vol. ii. p. 511; Heyne, *De Euphorione, et Excurs.* iii. *ad Virg. Eclog.* vi. 64, and *Excurs.* v. *ad Æn.* ii. See also *Ephemer. Liter.* Halens. 1824.

EUPHRATES, a large river of Asia, taking its origin from several sources in the great range of Mount Taurus. There are two branches in particular which dispute the honour of being the principal. One to the east, called Mured, rising not far from the town of Bayazid, traverses the southern part of Armenia Proper; the other, to the west, called by the inhabitants Frat, is formed under the walls of Erzeroum by the junction of two small rivers. The Frat and Mured unite their waters a little below the town of Arabkir, when the river descends rapidly towards the defile called the Pass of Nashar. It then winds along an elevated plain, and about twenty-two miles above Samosat, the ancient Samosata, forms a double cataract. Having now cleared all the obstacles that opposed its progress, it rolls majestically along through a wide and verdant valley. At Korna, about a hundred and thirty miles from its mouth, it is joined by the Tigris, and forms with it the Shet-al-Arab, or river of Arabia, one of the noblest rivers in the east. At this point the land sinks, and is occupied with meadows and morasses; but even in the driest season it is navigable for boats of considerable burden as far as Skukashu, a village about a day's sail farther up. Above this point the tides of the Persian Gulf reach twenty or twenty-five miles, and the river is navigated during six months of the year by flat-bottomed boats as far as Hibah. The Euphrates has three principal mouths; but bars of sand formed by the river, and which change in their form and situation, render the approach very dangerous. It is said that the tide, meeting with violence the downward course of the stream, divides its waters in the form of frothy billows. The course of the Euphrates before joining the Tigris is about 1400 miles; and adding a hundred and thirty miles for the distance from its junction with the Tigris to the sea, its whole course will be upwards of 1500 miles. Its greatest increase is in January, when it rises twelve perpendicular feet, in consequence principally of the melting of the snows on the Taurian range. Taking advantage of this circumstance, the ancient inhabitants of Asia Minor formed numerous artificial canals and lakes, for the double purpose of protecting the contiguous plains from inundation, and of preserving the superfluous waters for irrigation. The canal of Pallacopus, which was dug by the Babylonian kings, is one of these; and the Sea of Nejiff was also a gigantic work. In general, however, the country languishes under the wretched policy of the Turks; and these great works of art for protecting it against the overflowing streams, and at the same time for preserving the water for fertilising the soil, have fallen into neglect and disrepair. In the time of Alexander, the Tigris and Euphrates entered the sea by separate mouths. (Mannert, *Geographie von Indien*, vol. ii. p. 143; D'Anville, *Euphrates;* Niebuhr, *Voyage*, vol. ii. p. 228, 253, 261. See also Malte Brun, and an able memoir on the Euphrates in the *Journal of the Royal Geographical Society*, vol. iii. Lond. 1834.)

E lis
re.

EUPOLIS, a poet of Athens, born about 446 B.C., was one of the writers of the old comedy. He began to exhibit his plays at the early age of seventeen, and contended with Aristophanes for the prize 425 B. C. It is said that seven of his pieces were crowned with victory. In those days when the law of libel had not yet been invented, the great and powerful took very summary vengeance on those who had spoken disrespectfully of their characters. Thus Alcibiades is reported to have inflicted a punishment on Eupolis, which was utterly unworthy of his high name. It appears that Eupolis was a private soldier in the army commanded by Alcibiades; and in the voyage to Sicily that general ordered him to be lashed to a rope and plunged several times into the sea, in order to teach him, as he said, to speak with less freedom of his superiors (*Cic. Att.* vi. 1.). Eupolis perished in a battle against the Lacedæmonians, and it was in consequence of this disastrous defeat that the decree was passed by the Athenians to exclude poets from military service. The fragments of his works have been collected. (*Eupolidis Fragmenta, Gr. Lat. et cum Notis edid.* Rob. Walpole, 1805; *collegit Mart. Runkel*, 1829. See Meinecke, *De Eupolidi, veteris Comœdiæ Poeta*, Berlin, 1826; also Lucas, *Cratinus et Eupolis*, Bonn, 1826.)

EURE, a department of the north-east of France, formed out of the ancient Norman Bexin, the district of Saint André, Neuburg, a part of Perche, and of Ouche, Auge, Lienvin, and Roumois, all parts of the former country of Normandy. It is bounded on the north by the department of the Lower Seine, on the east by those of Oise and Seine-Oise, on the south by Eure-Loire and Orne, and on the west by Calvados. The extent is 2420 square miles, or, according to the *Almanach Royal*, 623,283 hectares, of which 371,136 are arable land, 108,000 woods, 11,931 vineyards, 18,537 meadows, 2726 gardens, 47,581 uncultivated land, and the remainder roads, rivers, and the sites of towns. It is divided into five arrondissements, thirty-six cantons, and 843 communes, inhabited by 421,480 persons. It is generally a level country, but a few hills are to be seen on the borders of the Seine, the Rille, and the Eure, though none of them are more than three hundred feet above the level of the sea. The soil generally consists of vegetable matter, mingled with clay and sometimes marl, resting on a bed of chalk or stone. The cultivation is tolerably conducted; so that, with the natural fertility of the soil, the department, though rather densely peopled, produces more corn than the population requires. The chief kind of corn is wheat, the growth of which occupies a larger space than rye, oats, and barley together. Flax is largely cultivated, and, from its length, fineness, and colour, is highly esteemed. The seed of this plant is drawn either from Flanders or from Riga. Some hemp is also produced. The horses of the department, of the pure Norman breed, have always been celebrated, and, though they had nearly lost their high character, have of late been more carefully bred and much improved. The breed of cows is remarkably good; and the calves are much in request in the neighbouring departments. Sheep have been neglected, but have recently increased; and those on the coast, known as *Moutons du Pré Salé*, are highly valued for their excellent meat. Of late years attempts have been made to improve the wool by a mixture of merinos. Fruit is very abundant, especially apples, from which much cider is made. The wine is but of moderate quality, and will rarely bear to be kept longer than three years. There are no mines but of iron, which yield annually 400 tons.

This department is a manufacturing part of France; and cotton, linen, and woollen cloths of every kind, are fabricated. There are large establishments for making copper ware of all kinds, the various descriptions of paper, nails, pins, and needles, glass for windows, and glass bottles, and jewellery and trinkets. These employments occupy the larger portion of the inhabitants. Such goods form the trade; in addition to which, fire-wood, timber, cattle, honey, wax, and corn, are furnished to the districts surrounding the department.

EURE AND LOIRE, a department of the north-west of France, formed out of parts of the ancient Orleannois, and a portion of the duchy of Maine. It is bounded on the north by the department of the Eure, on the east by that of Seine-Oise, on the south by those of Loiret and Loire-Cher, and on the west by those of Sarthe and Orne. Its extent is 2420 square miles, or, according to the *Almanach Royal*, 602,752 hectares. The civil divisions are four arrondissements, twenty-four cantons, and 460 communes, containing 265,943 inhabitants. The face of the country is level in general, with a few hills, none rising to a greater height than 500 feet. The soil in the middle and west of the department is the best. It consists, for the most part, of thick layers of grey, yellow, or black clay, intermixed with sand, or of calcareous earth, and is on the whole fertile, but in the south-west, especially in the arrondissement of Nogent, it is sandy and dry, and many tracts of land are so poor as to be uncultivated. None of the rivers of this department, even those from which it is named, are navigable till they have left it. The agriculture is better conducted than in most of the departments of France; and the production of the various kinds of corn so far exceeds the consumption, that nearly 200,000 quarters are annually exported to the other parts of the kingdom. The wheat is remarkably fine, and is prized on account of its being easily preserved for a long time, and best adapted for sea voyages. The cows are small, but yield good butter for the supply of Paris, and fat oxen and calves for the markets of Poissy and Sceaux. The sheep are numerous, but not remarkable, except some flocks whose wool has been improved by crosses with the merino races. Wine is not extensively produced, nor of the best quality; but in some parts there is an abundant supply of apples, from which cedar is made as the common drink of the inhabitants. There are no mines but of iron, and these yield about 1200 tons annually, which is not more than one third of the demand. The manufactures are not extensive; but leather, paper, cotton goods of various kinds, serges, flannels, and other coarse woollens, hosiery, hats, caps, household linen, such as sheetings and table linen, and some earthenware, are furnished. The department draws its supply of fuel from its own woods, which cover about one twelfth part of the whole surface.

EURIPIDES, the son of Mnesarchus, a celebrated tragic poet, was born 480 B. C. in the island of Salamis, to which place his parents had been obliged to fly from Athens at the time it was threatened by the invasion of Xerxes. His birth took place on the very day that the battle was fought near the strait Euripus, the prelude to the more decisive engagement in the vicinity of Salamis. To commemorate this event, the embryo poet was called Euripides. As of every illustrious man, there are some stories told which predicted his future destiny, and, amongst these, an oracle declared that he should be crowned at the Olympic games. His father, misunderstanding its true meaning, trained him for athletic exercises, and it appears that he was victorious at the games celebrated in honour of Theseus and Ceres. But fate had destined him for a higher and a more ennobling occupation; he began to devote himself to the study of eloquence under Prodicus of Chios, and to take lessons from the philosopher Anaxagoras. It is said by some that he was a disciple of Socrates, but we can scarcely credit this statement, as the philosopher was thirteen years younger than the poet. The persecutions which Anaxagoras underwent from the bigotry of the Athenians clearly demonstrated to Euripides the dangerous path which he was pursuing, and induced him to renounce the study of philosophy, and direct his attention to the stage. This took place, it is said, in his eighteenth year, and in 455 B. C. he succeeded in gaining the third prize. Of all the plays which he wrote, only five, according to Varro, were reckoned worthy of being crowned; but this fact may be explained by the violent spirit of rivalry and jealousy which seems to have prevailed at Athens at this time. In his domestic affairs he was by no means fortunate; both his wives disgraced him by the irregularity of their lives; and from this circumstance probably arose his violent hatred of the sex, the weakness of which he took every opportunity of ridiculing and exposing. His private grief became the butt of the comic writers of the day, and Aristophanes more particularly held him up to the ridicule of the public. It was no doubt in consequence of these incessant attacks that Euripides determined to retire to the court of Archelaus, king of Macedonia, who reigned from 413 to 339 B. C., and was then the beneficent patron of literature and science. By him he was received with all that respect to which his distinguished talents entitled him, and some say that he was appointed one of his principal ministers. Here he resided till his death (406 B. C.), which was as full of tragic circumstances as any story ever exhibited upon the stage. As he was strolling through a wood, a pack of the royal hounds attacked the poet, and tore him in pieces. His remains were removed to Pella by the king, and every honour was shown to his memory. The Athenians were now anxious to procure his ashes, but Archelaus refused to gratify those who had neglected the poet in his lifetime.

It is difficult to convey an exact idea of the character of Euripides as a dramatist to those who have not read the original. His language is raised but little above that of common conversation, yet he possesses the rare art of choosing his words so well, that the most common are ennobled by their happy combination. He has none of the dithryambic boldness of Æschylus, none of the pompous magnificence of Sophocles, yet he touches the hidden springs of human passion with a masterly hand. Still he is full of faults, which the good taste of all ages must condemn. He is too fond of learned digressions, "of wise saws" and philosophical maxims; and the plots of his plays are not always so clear and unembarrassed as they ought to be. Of eighty-four tragedies, of which Barnes has given a list, only nineteen have been preserved. They are, *Hecuba, Orestes, Phœnissæ, Medea, Hippolytus, Alcestes, Andromache, Supplices, Iphigenia in Aulis, Iphigenia in Tauris, Rhesus, Troades, Bacchæ, Cyclopæ, Heraclidæ, Helena, Ion, Hercules Furens, Electra.*

There are numerous editions of his works. But we believe that of Barnes, Cambridge, 1694, fol. and that of Matthiæ, Leipsic, 1813–1829, vol. ix. to be the best.

EUROCLYDON, (from Ευρος, *the east wind*, and κλυδων, *a wave*), is a species of wind, of which we have an account only in the Acts of the Apostles (xxvii. 14), and concerning the nature of which critics have been much divided. Bochart, Grotius, Bentley, and others, substitute another reading, supported by the Alexandrian Manuscript, and the Vulgate, namely, Ευρακυλων or *Euro-aquilo;* but Mr Bryant defends the common reading, and considers the *Euroclydon* as an east wind which causes a deep sea or vast inundation. He maintains, in opposition to the reasoning of Bentley, who supposes that the mariners in the ship, the voyage of which is recited in this passage, were Romans, that they were Greeks of Alexandria, and that the ship was an Alexandrian ship employed in carrying corn to Italy; and, therefore, that the mariners had a name in their own language for the particular typhonic or stormy wind here mentioned. He also shows from the passage itself, that the tempestuous wind called *Euroclydon* beat upon the island of Crete; and hence, as this is a relative expression, referring to the situation of the person using it, who was at that time to the windward or south of it, the wind blew upon shore, and must have come from the south or south-east, which, he adds, is fully warranted by the point where the ship was, and the direction it ran in afterwards, which was towards the north and north-west.

EUROPA, in fabulous history, a daughter of Agenor, king of Phœnicia and Telephassa. She was so beautiful that Jupiter became enamoured of her; and, in order to seduce her, he assumed the shape of a bull, and mingled with the herds of Agenor, whilst Europa, with her female attendants, were gathering flowers in the meadows. Europa caressed the beautiful animal, and at last had the courage to sit upon his back. The god took advantage of her situation, and with precipitate steps retired towards the shore, crossed the sea with Europa on his back, and arrived safe in the island of Crete. Here he assumed his original shape, and declared his love. The nymph consented, though she had once made vows of perpetual celibacy, and became mother of Minos, Sarpedon, and Rhadamanthus. After this amour with the king of the gods, Europa married Asterius, king of Crete. This monarch, seeing himself without children by Europa, adopted the fruit of her loves with Jupiter, and always esteemed Minos, Sarpedon, and Rhadamanthus, as his own children. Some suppose that Europa lived about 1552 years before the Christian era.

EUROPE,

Comparative advantages and disadvantages of this division of the globe.

ONE of the great divisions of the globe. On a first view Europe appears to be less favoured by nature than the other quarters of the globe over which it has obtained so great an ascendancy. It is much smaller in extent; its rocky and mountainous surface does not admit of those noble rivers, like inland seas, which lay open the remotest regions of Asia and of America to the commerce of the world. Its vegetable productions are neither so various nor so exuberant; and it is poorly supplied with the precious metals, and with many of those commodities on which mankind set the greatest value. On the other hand, the climate of Europe, if it nourishes a less luxuriant vegetation, is of an equal and temperate kind, well adapted to preserve the human frame in that state of health and vigour which fits it for labour, and promotes the developement of the intellectual and moral powers. The mountains that intersect its surface are barriers which enabled infant communities to protect themselves from violence, and to lay the foundation of arts, knowledge, and civilization. If it has few large navigable rivers, its inland seas and bays are, from their position and extent, the finest in the world, and have been the means of creating and nourishing that commercial spirit which has been one great source of its improvement. Though comparatively deficient in gold and silver, it is abundantly supplied with those useful metals and minerals which minister still more essentially to the wants of civilized life. Its apparent defects have become the source of real benefits, and the foundation of its grandeur. The disadvantages of its soil and climate have excited the industry of its inhabitants, given them clearer ideas of property, kindled a resolute spirit to defend their rights, and called into existence that skill and enterprise, and those innumerable arts and inventions, which have enabled the inhabitants of this apparently barren and rocky promontory to command the riches and luxuries of all the most favoured regions of the globe. It is only in Europe that knowledge and the arts seem to be indigenous. Though they have appeared at times among some of the nations of Asia, they have either stopt short after advancing a few steps, or they have speedily retrograded and perished, like something foreign to the genius of the people. In Europe, on the contrary, they have sprung up at distant periods, and in a variety of situations; they have risen spontaneously and rapidly, and declined slowly; and when they disappeared, it was evident they were but crushed for the time by external violence, to rise again when the pressure had subsided. It is only in Europe, and among colonies of Europeans, that the powers of the human mind, breaking through the slavish attachment to ancient usages and institutions, have developed that principle of progressive improvement, of which it is impossible to calculate the final results. The rudest tribe in Europe, in which this principle has taken root, has a certain source of superiority over the most improved nations of Asia and Africa, where society remains perfectly stationary. If these nations are ever destined to advance in civilization, they must borrow from Europe those arts which she has invented, and which belong to civilized life in every climate. But the tenacious adherence of rude nations to the customs and superstitions of their ancestors, will not allow us to hope that the benefits of civilization will be rapidly diffused in this way. It is more probable that colonies from the older states of Europe will multiply, as the population becomes more and more redundant; and that these colonies will carry the arts and knowledge, the language and manners of Europe with them, to the other quarters of the world. From prejudices on both sides, it is found that two races, in very different stages of civilization, do not readily amalgamate; and it is therefore probable, that the feebler inhabitants of these countries, like the American Indians, will be gradually displaced by the continual encroachments of the more energetic race of Europe. Such a change, however, must take place slowly, and there is nothing in it to alarm humanity. The vast number of tribes that people Asia and Africa seem born only to be the victims of savage superstition and ferocious tyranny. No treatment they are likely to experience from European colonies can render their condition worse; and were the whole swarm of these nations to die out in the course of nature without being renewed, no great deduction would be made from the sum of human enjoyment. Should the state of things we have been contemplating, and which seems to arise naturally out of the circumstances of Europe and the other quarters of the globe, be realized, it will be curious to reflect on the circle of changes which will then be completed. The ancient inhabitants of Europe, as well as the modern, were originally colonies sent off from the surplus population of Asia. Here they have thrown off their barbarism, invented and improved arts and sciences, and carried their social institutions to a high degree of perfection; and now, in the maturity of their strength, they are throwing back their surplus numbers upon Asia, to conquer and supplant the remains of those tribes from which they originally sprung.

Bounda- ies and xtent.

Europe is bounded on the north and west by the Arctic and Atlantic Oceans; on the south by the Mediterranean, the Black Sea, and Mount Caucasus; on the east by the Caspian Sea, the river Ural, and the Uralian Mountains. These are the limits proposed by Malte Brun, and adopted by Balbi and other recent geographers, as corresponding better with the natural divisions of the earth's surface than the old boundary, which on the east side passed from the Sea of Asoph to the Uralian Mountains, by the courses of the Don, the Wolga, and the Kama. The greatest length of the continent of Europe is from Cape St Vincent to the Sea of Kara, in the direction of north-east and south-west, and is 3490 English miles. Its greatest extent from north to south is from Cape Matapan to Cape North, 2420 miles. The superficies of Europe, including the Azores, Iceland, Nova Zembla, and all the other islands belonging to it, is 3,700,000 English, or 2,800,000 geographical square miles.

limate.

The climate of Europe is distinguished by two peculiarities. It enjoys a higher mean temperature than any of the other great divisions of the world in the corresponding latitudes; and it is not subject to such violent extremes of heat and cold. These advantages it owes chiefly to its numerous seas, inland bays, and lakes, which render its temperature similar to that of islands; and partly also, according to Humboldt, to its situation at the western extremity of the greatest range of dry land on the surface of the globe; the western sides of all continents being warmer than the eastern. Europe lies almost entirely within the temperate zone, not more than one fourteenth part of its surface being within the arctic circle. Only a very small part of it is uninhabitable from cold, and it nowhere suffers much from excessive heat. The mean temperature at its southern extremity, in the latitude of 36°, is about 66° of Fahrenheit; and at Cape North, in the latitude of 71°, where the mean temperature is 32°, the cold is not greater than in the latitudes of 55° or 56° on the east coasts of Asia and America. Hence Europe is habitable at a higher latitude by 12° or 14° than either of these continents. The following table, taken from Humboldt's *Memoir on the Distribution of Heat* (abridged in Dr Thomson's *Annals of Philosophy*, xi. 188), shows the difference in temperature between Europe and the eastern shores of Asia and America at the parallel of 40°; the difference is much greater at the parallel of 60°.

	Lat.	Mean Temperature		
		of the Year.	of Three Winter Months.	of Three Summer Months.

Pekin..........	39·54	55·2	26·8	82·6
New York......	40·40	53·8	29·8	79·2

There is a difference of the same kind between the temperature of the sea-coasts of Europe and the interior. In islands, and on the sea-coast, the mean temperature of the year is higher, and the heat is more equally distributed through the different seasons. As we advance from the coast eastward the mean annual temperature diminishes, but the heat of summer and the cold of winter increase. Thus London has the same mean annual temperature as Vienna, but it has the summer of Petersburg, and the winter is warmer than at Milan. The Mediterranean, the Baltic, and inland lakes, produce the same effect as the ocean, in an inferior degree. The two following tables are taken from Humboldt (*Annals of Phil.* xi. 188): the first shows the temperature of the year, and the various seasons in places having the same latitude; the second shows the different distribution of heat through the various seasons in places having the same mean annual temperature.

Mountains.

The mountains of Europe are more numerous in proportion to its extent than those of the other great continents, but they are of less elevation than the mountains of America and Asia. The highest and the most extensive chains in Europe run generally in the direction of east and west, and are placed near its southern shores. The central mass of the Alps, with which all the other mountains in the south of Europe are connected, forms the summit of the continent, and determines the position of the surface and the course of most of the rivers. From this central point the surface of the land descends to the sea by a series of valleys, skirted by subordinate chains. The three countries to the southward of the Alps and their branches, Greece, Italy, and Spain, consist of mountainous peninsulas projecting into the Mediterranean. The countries to the west, north, and east of the Alps, which present more extensive plains and gentle declivities, are the seats of the three principal monarchies in the south of Europe. Austria, seated on the eastern declivity, rules over the countries watered by the Danube; France occupies the western declivity, and the countries watered by the principal streams that flow to the west; and Prussia the countries watered by the streams that flow to the north. If we descend from the Alps to the sea in a western direction, the first valley we meet with is the level part of Switzerland, between the Alps and Mount Jura, elevated from 1600 to 1800 feet above the sea: the second, between Jura and the Cevennes, some hundred feet lower; and the third, and lowest, extends from the Cevennes to the Atlantic. In a north and north-east direction, the first valley is Bavaria, the second Bohemia, both of which are completely inclosed by mountains; the third, consisting of Silesia, Brandenburg, and Poland, terminates in the Baltic. In an eastern direction the first valley is Austria, the second Hungary, both encircled with mountains; the third, Bulgaria, extends to the Black Sea. South from the Alps we have first the valley of Lombardy, and then the narrow coast of Genoa. The vast plain occupied by Russia and the eastern part of the Swedish peninsula may be considered as a prolongation of the valley of Prussia and Poland, extending to the Dofrines on the west, the Uralians on the east, and Mount Caucasus on the south. Thus, in a general point of view, the elevation and declivity of the large plains of southern Europe bear a certain relation to the position and distance of the central mass of the Alps.

---

[1] Copenhagen is about 620 miles east from Edinburgh: Moscow about 1000 miles farther.

Alps.

The principal mass of the Alps extends in a semicircle from Nice, on the shores of the Mediterranean, to Trieste, on the Adriatic, a distance of 550 miles. Southward of Mont Blanc, the Alps consist of a single chain, with many lateral branches, which lie chiefly on the west side; but immediately to the eastward of Mont Blanc, the principal chain divides into two, which inclose the sources of the Rhone. These meet, again, at St Gothard, and, on the east side of it, part into three chains, one of which loses itself in Bavaria, another in Austria near Vienna, and the third terminates near Trieste. A lateral chain, of no great elevation, passes eastward, and connects the Alps with the mountains of European Turkey. Smaller branches connect the Alps with the Bohemian and Carpathian Mountains on the north, with the Vosges and Cevennes on the west, and, through the latter, with the Pyrenees. The Appennines are but a prolongation of the Alps on the south. Mont Blanc, the loftiest of the Alps, and the highest mountain in Europe, has an elevation of 15,680 English feet; and Mount Rosa, the Jungfrau, the Schreikhorn, and several other summits, approach to this height. The elevation of the chain diminishes towards both extremities. In general, the escarpments, or steepest sides, are turned towards Italy, and the lateral and subordinate branches are most numerous, and extend farthest, on the opposite side. The central chain of the Alps consists chiefly of granite, gneiss, sienite, and other primitive rocks. Among the lateral ridges, to the westward of St Gothard, calcareous rocks, with clay-slate and mica-slate, abound on the side of France; on the side of Italy the ridges are narrower, magnesian rocks abound, and the clay-slate is wanting. On both sides are found great deposits of gravel, and large detached blocks or boulders, often at a vast distance from their original situations. Eastward from St Gothard, the central chain is accompanied on each side by a calcareous chain of great elevation. Though the summits of the Alps are steep and rocky, and the higher valleys are filled with glaciers, there is much good soil below. The vine grows to the height of 1600 feet above the sea, the oak to the height of 3390, corn to 4200 feet, and the larch to 6720 feet. At 6400 feet above the sea, we have the climate of Lapland in latitude 68°, so that a degree of latitude in the northern half of the temperate zone in Europe corresponds to an elevation of about 290 feet. The inferior limit of perpetual snow, according to Humboldt, is at the height of 8760 feet, in the latitude of 46°. (Humboldt *De Distributione Geographica Plantarum*, Paris, 1817, p. 122–165).

The chain of the Pyrenees, which is next to the Alps in elevation, runs in the direction of east and west. Its length is about 240 miles; but, if we include the Cantabrian Mountains, which continue in the same line without interruption, the whole length will be about 500 miles. The central chain of the proper Pyrenees is of granite, but the most elevated summits are of secondary limestone, and lie on the south side of the granite. Mont Perdu, esteemed the loftiest of the whole range, consists of fetid limestone, and rises to the height of 11,270 feet. The south side of the Pyrenees is rugged and precipitous; but on the north there is a gradual descent to the plains of France by a series of parallel ridges diminishing in height. The Cantabrian Mountains are lower than the Pyrenees, and present their steepest sides to the north. There are four other chains of mountains in Spain, all running in a direction approaching to east and west, and all connected with one another and with the Pyrenees. The most elevated of these is the Sierra Nevada, the southmost, one of whose summits rises to the height of 11,660 feet. (*Laborde*, i. 173). The inferior limit of perpetual snow on the Pyrenees is at the height of 8960 feet. The red pine rises to the height of 7480 feet, which is about 700 feet higher than any species of trees on the Alps.

The Appennines form an uninterrupted chain 750 miles in length, extending from the south-west termination of the Alps near Nice to the Straits of Messina. The north-west division, which skirts the basin of Lombardy, consists chiefly of greywacké; from Tuscany to near the southern extremity, the prevailing rock is secondary limestone. Granite and other primitive rocks are found at the two extremities in Liguria and Calabria, but are wholly wanting in the intermediate space. The most considerable elevations are about the middle of the chain, where Il Gransasso rises to the height of 9570 feet.

The Carpathian and Sudetic Mountains, with the Erzgebirge and Boehmerwald, may be considered as forming one continued chain, the length of which, from the point where it strikes the Danube in Hungary, to the point where it strikes the same river in Bavaria, is about 1200 miles, exclusive of the transverse branches which separate Moravia from Bohemia and Hungary. The declivities of this long range of mountains are steepest on the south side. The elevations are lowest on the west, and generally increase as we advance eastward, till we come to the sources of the Thiess in the north of Hungary, after which they again decline. The Fichtelberg, at the westmost point of the chain, is 4030 feet high: Schnekoppe, the highest of the Sudetic Mountains, is 5280 feet, and Lomnitz in Hungary, the loftiest of the whole range, is 8460 feet. None of these mountains rise to the region of perpetual snow, the inferior limit of which, according to Wahlenberg, is about sixty feet above the summit of Lomnitz. The most elevated parts of these mountains consist of primitive rocks; corn and fruit trees are said to grow at a greater height upon the Carpathian's than upon the Alps, though the latter are two degrees farther south.

D nes.

The chain of the Dofrines, or great Scandinavian Alps, is about 1000 miles in length, and has a general elevation of from 6000 to 6500 feet. The altitude of Skagstlos Find, the highest mountain of the chain, is 8400 feet. These mountains consist almost entirely of primitive rocks, and present their steepest sides to the west. On Sulitelma, the highest mountain of this chain in Lapland, in latitude 67·10, the inferior limit of perpetual snow is at the height of 3500 feet.

U s.

The Uralian Mountains, which form the boundary of Europe on the north-east, are but imperfectly known. Some of their summits are covered with perpetual snow, but their height is believed not to exceed that of the Scandinavian Alps. They consist chiefly of primitive rocks. The whole length of the chain, which runs nearly north and south, is about 1400 miles.

M tains
of rkey.

Of the mountains of European Turkey we know as little as of the Uralian chain. From a central point, nearly equidistant from the Danube, the Adriatic, and the Ægean Sea, three chains proceed in different directions; one, the ancient Hemus, runs eastward to the Black Sea; a second, north-westward, till it joins the Carnic Alps; and a third, southward, through the peninsula of Greece. These principal chains send out many branches, but neither their height nor their geological structure is known with any degree of accuracy.

Ce nes.

The Cevennes in the south of France extend about 300 miles in length from north to south, and their two most elevated summits, Mont d'Or and Cantal, rise to the height of 6400 and 6170 feet. Mount Jura, between France and Switzerland, has nearly the same elevation. The Vosges, a small chain in the north-east of France, rise nowhere more than 4600 feet above the sea.

M tains
of tain.

The mountains of Britain extend, with some interruptions, over a space of 630 miles, along the west side of the island. They are not placed in chains, but rather in irregular groups, and consist chiefly of primitive and transition rocks. Snowden in Caernarvonshire, the highest mountain in Wales, has an elevation of 3570 feet. Bennevis in Inverness-shire, which rises 4336 feet above the sea, is the highest land in the island.

Vo noes.

There are thirteen volcanoes in Europe, all situated in the vicinity of the sea, and of which the following are the most remarkable: Mount Ætna, in Sicily, is 10,940 feet in height. Its eruptions happen very irregularly; sometimes fifty or a hundred years have intervened between one eruption and another; at other times less than one year. Mount Vesuvius, near Naples, which lies about two hundred miles north from Ætna, is 3820 feet high. Its eruptions are less frequent than those of Ætna. Stromboli, which occupies an island in the Mediterranean, about eighty miles north from Ætna, is the only volcano in Europe that throws out smoke or flames constantly. Heckla, near the south coast of Iceland, is 4980 feet high. Its eruptions are not frequent. The last was in 1783.

Riv

Europe is well watered with rivers, but they are but brooks compared with the mighty streams of Asia and America, and, from the unevenness of the surface, afford in general no great extent of inland navigation. The Danube, the largest river that is entirely in Europe, is about 1500 miles in length, and waters a superficies of 370,000 square miles. But the Amazons, though only twice the length of the Danube, waters a surface seven times as large, and equal to four fifths of the continent of Europe; and, as the quantity of rain that falls in tropical countries is much greater than in northern latitudes, it is probable, notwithstanding the increased evaporation there, that the Amazons conveys more water than all the rivers of Europe put together. If we divide the length of the Danube into a hundred parts, the length of the principal rivers of Europe, expressed in these parts, will be as follows:

Danube	100
Wolga	130
Dnieper	72
Don	69

A much smaller proportion of the waters of the European continent flows into the Mediterranean than the extent of its coasts would lead us to expect. The high mountains that range along the south of Europe, parallel to its shores, from Gibraltar to Constantinople, turn the course of the large streams in an opposite direction. Though the length of the line of coast between the points last mentioned, without computing minute sinuosities, is 4000 miles, or one fourth of the circumference of Europe, not more than one tenth of the waters of this quarter of the globe fall into the Mediterranean. The Black Sea, on the other hand, which presents only 850 miles of coast on the side of Europe, receives one fourth of its waters. It will be seen from the subjoined table that one tenth part of the waters of Europe flows into the Caspian by the Wolga; that the Black Sea and the Baltic alone receive one half, whilst only about one sixth falls into the Atlantic. If the whole of the river waters of Europe be divided into a hundred parts, their distribution will be nearly as follows:

	Length of Coast in Miles.	Water conveyed by Rivers in parts.
Whole length of the bounding line of Europe, and whole quantity of water	16,000	100
Mediterranean, from Gibraltar to Constantinople	4000	10
Black Sea and Sea of Asoph	950	26
The Baltic to the Naze of Norway	3340	25
The Atlantic, from Gibraltar to Cape North	3640	17
The Arctic Ocean, from Cape North to the Sea of Kara	2200	12
The Caspian Sea (in Asia)	......	10

We are not acquainted with the height of the sources of many of the European rivers above the sea. Those of the Danube, according to Malte Brun, are from 2100 to 2200 English feet, which gives a fall of one foot and a half per mile, but near the sea the inclination is less; for at Buda, 900 miles from the mouth of the river, its height, according to Wahlenberg, is 229 feet, which gives a fall of three inches per mile for the lower part of its course. It begins to be navigable at Ulm. In general the rivers

Europe.

of Russia, Poland, and the north of Germany, flow over a more level surface, and are more navigable, than those of the south of Europe. Professor Robison states, on the authority of the Abbé Chappe, that the sources of the Wolga are but 480 feet above the ocean (*Encyc. Brit.* article RIVER); but as the Caspian Sea, in which this river terminates, is found to be 324 feet below the Black Sea, this increases the space through which the waters of the Wolga descend to 804 feet, in a course of 2000 miles. The average fall may therefore be about two inches and a half per mile.

Islands.

The islands of Europe, including Nova Zembla and Iceland, occupy a space equal to 280,000 square miles, or one eleventh part of the surface of the continent; and of this space the area of the British isles amounts to rather less than one half. The Black Sea is the only large sea connected with Europe in which there are no islands worthy of notice.

Inland seas. Mediterranean.

The Mediterranean, the noblest inland sea in the world, forms the southern boundary of Europe, separating it from Africa, and partly also from Asia. It may be considered as the bottom of a vast basin formed by the Pyrenees, Alps, Mount Hemus, Taurus, Libanus, and Atlas. These mountains are everywhere near its shores, which are consequently narrow and much inclined. Hence there are no such extensive plains as Hungary or Poland near the coast of this sea, and hence also no very large rivers fall into it except the Nile; and altogether it receives a smaller quantity of water from rivers than the Black Sea or the Baltic, though six times larger than either. Its length is about 2350 miles, its breadth is extremely various, and its surface (exclusive of the Black Sea) is nearly equal to 1,000,000 of square English miles, or something less than a third part of the continent of Europe. It is generally of great depth, and its numerous islands, which have uniformly a rocky surface, appear to be the summits of marine mountains.

Baltic.

The Baltic, the greatest inland sea that is entirely in Europe, is about 1200 miles long, of very unequal breadth, and presents a surface of 175,000 square miles, exclusive of islands. It occupies the bottom of another large basin, 850 miles in breadth, and 1400 in length, extending from the Norwegian mountains on the north and west, to the Carpathians on the south, and to the high lands in which the Dnieper, Don, and Wolga rise, on the east. This basin, equal to one third of the surface of Europe, has a very different character from that of the Mediterranean. The mountains are not very elevated, and are so placed as to leave a large tract of land very little inclined between them and the Baltic, over which, especially on the south side, many considerable rivers flow with a gentle current. Hence the country round the Baltic is much more level than round the Mediterranean; lakes are numerous in the low grounds, from the want of declivity; the sea itself is comparatively shallow, and, receiving a much greater quantity of river water, it is much inferior in saltness. The commerce of the Baltic is annually interrupted by the ice, which endures four months in the Gulfs of Bothnia and Finland. The whole of this inland sea has sometimes been frozen over for a short time, but this is of rare occurrence.

Black Sea.

The Black Sea, which belongs only partly to Europe, is 690 miles long and 360 miles broad, and, including the Sea of Asoph, presents a surface of 170,000 square miles, being almost of the same magnitude as the Baltic. It derives four fifths of its water from Europe, and is curiously distinguished from the other seas of this quarter of the globe, by its being almost totally destitute of islands.

The White Sea is 450 miles in length, of a very irregular figure, and occupies a space equal to 35,000 square miles. It receives some considerable rivers, but is frozen during six months of the year.

The lakes of Europe are numerous, and are of two kinds; those which lie in cavities at the foot of high mountains, and which are generally deep, such as the lakes in the Alps, on the east side of the Norwegian mountains, and among the mountains of England and Scotland; and those which are formed in level countries from the want of a sufficient declivity to carry off the water, such as the lakes in Finland, Poland, and Brandenburg. Four fifths of the lakes of Europe are in the country round the Baltic.

The soil of Europe has neither the extremes of luxuriance nor sterility which belong to the soil of the other great continents. If it does not yield the rich fruits of tropical climates, it is not deformed by the burning sands of Africa, or the pestilent swamps of America. It does not pour forth its riches spontaneously, but, soliciting the care and the labour of man, it requites his industry with what is necessary to supply his wants; and, by exercising and sharpening his powers of mind, has given birth to those arts which place the productions of the most favoured climates at his disposal. Many of the plants which have been domesticated in Europe are natives of distant countries. The vine, the olive, and the mulberry, are said to have been brought from Syria by the Greeks; the Arabians introduced cotton; maize was received from the Indian tribes of America; the walnut and peach come from Persia; the apricot from Armenia; and the sugar-cane from China. There are not very many plants belonging to the tropical regions that absolutely refuse to grow in Europe, but an enlightened economy finds other productions more profitable. Besides sugar and cotton, the banana, the orange, citron, fig, pomegranate, and date, grow in the south of Europe. But the more delicate fruits are confined to southern latitudes, and disappear one by one as we advance northward. And it is worthy of remark, that the zones in which they grow generally follow the lines of equal summer heat, and run obliquely across the continent in the direction of south-west and north-east. If a line be drawn on the map from Brest to Konigsberg, skirting the southern shores of the English Channel and the Baltic, the zones that limit the growth of different plants will run nearly parallel with this line. (Young's *Travels in France*, i. 306.) This holds generally in the south and middle of Europe; but in the extreme northern parts, and especially with regard to plants that require a moderate heat continued for a considerable time, the lines that limit the growth of certain vegetables seem to follow a different course, and decline towards the south as we advance eastward, in consequence of the increasing severity and length of the winter. It is scarcely necessary to say, that the zones, traced as proper for different plants, only mark the limits within which their cultivation is found advantageous. Most of them will grow beyond these limits; but they either require some peculiar advantages of soil or situation, or they are less profitable than other kinds of produce.

The sugar cane, one of the most desirable tropical plants, grows in Sicily and the south of Spain, in the latitude of 37° and 38°. The culture of it, which was once extensive in the latter country, has not yet been entirely abandoned, even since sugar was procured from the West Indies. Cotton is cultivated in the south of Spain on a small scale, to a greater extent in Sicily, the south-east angle of Italy, and in Greece and its isles, as high as the latitude of 41½°; we find it again at Astracan, in the latitude of 46°. The

---

[1] Laborde's *View of Spain*, ii. 122-125; Storch, *Tableau de la Russie*, ii. 250; Humboldt, *De Distrib. Geog. Plant.*

orange and lemon come to perfection in the west of Europe, only in the countries to the south of the Pyrenees and Apennines, within the latitude of 43° in Spain, and 44° in Italy. The olive does not succeed on the west coast of France in the latitude of 43°, but grows as far north as 44° or 45° on the east of France, and in Italy. Attempts to raise it at Astracan, in latitude 46°, have not succeeded, on account of the rigour of the winter. The fig and the pomegranate, which accompany the olive in the west of Europe, are found in the Taurida in the east, at the latitude of 46°, where the olive will not grow, a proof that these trees bear the winter cold better. (Young's *Trav.* i. 311; Storch, ii. 309.) The climate proper for maize is found to terminate on the west coast of France at 45½°; on the Rhine at 49°; on the Elbe at 50° or 51°. Rice has nearly the same geographical range, but requires a peculiar soil and situation.[1] The culture of the vine extends as far north as the latitude of 47½° on the Atlantic coast; on the Rhine to 50½°; and on the Oder to 52°. In Russia it grows as far north nearly as 52°, but is not cultivated beyond 50°. (Young, i. 306; Storch, ii. 310, 323.) The mulberry generally accompanies the vine. The limits of the culture of the common cerealia are not so well defined, as the necessities of man oblige him to raise corn under the most unfavourable circumstances. In a general point of view, however, the parallel of 57° or 58° may be regarded as the northern limit of the cultivation of wheat in Europe. It is raised as far north as 60° or 61° in Finland, but only in some favoured spots. In Russia, generally, it is chiefly confined to the provinces under the latitude of 57°. (Thomson's *Trav. in Sweden*, 409; Storch, ii. 229, 240.) The hardier cerealia, rye, oats, and barley, are cultivated in some sheltered situations on the coast of Norway, as high as the latitude of 69° 55′. But on the east side of the Norwegian mountains these grains scarcely ripen in the latitude of 67° or 68°; and farther east, in Russia, it has been found impossible to carry cultivation of any kind beyond the latitude of 60° or 62°. Barley, which accommodates itself better than any other grain to these high latitudes, by shortening the period of its growth, is sown and reaped within the space of seven or eight weeks. But the introduction of potatoes promises to be of vast advantage in these cold regions, as this plant thrives and yields a produce of thirty or fifty fold in places where grain often will not ripen.[2] Peaches and apricots succeed with much care as far north only as the latitude of 50° in Russia; melons as far as 52°. The plum and the cherry grow wild as far north as 55°, but are carried farther by cultivation. (Storch, ii. 302, 304, 308.) Fruit trees and the oak terminate in Sweden, at Geffle, in the latitude of 61°; but the pine and the birch advance within the arctic circle; and the former grows to the height of sixty feet in the latitude of 70°. The black-berry and the whortle-berry grow in Lapland, and the gooseberry even in Greenland. Tobacco is extensively cultivated over the greater part of the continent of Europe, from Sicily to Sweden. Flax and hemp have as extensive a range as corn, but they are raised in the greatest perfection between the latitudes of 45° and 60°.

We have stated that the superficial extent of Europe is about 3,700,000 square miles. If we draw an incurvated line from a point in the Uralian Mountains, about the latitude of 60° or 61°, to the west coast of Norway, in the latitude of 69°, passing through the Lake Onega, and a little to the northward of the Gulf of Bothnia, this line will mark the extreme limits of cultivation, and will cut off a space equal to 550,000 square miles, or nearly one seventh of Europe. The space cut off, however, is not entirely useless, as a part of it produces pasturage and wood. The cultivation of rye, oats, and barley, is confined to the region south of this line, and includes more than five sixths of Europe; but in the northern parts of this zone only a very small proportion of the land will bear corn. The region adapted to the cultivation of wheat comprehends about four sevenths of Europe, and includes all the densely peopled parts. The region of the vine extends over three sevenths of Europe.

Metals.

Europe, in proportion to its extent, is probably richer in mineral wealth than the other quarters of the globe. It contains all the metals except platina; and though it affords gold and silver only in limited quantities, iron, copper, lead, with coal and salt, commodities of greater value to society, are abundant and widely distributed. The mountains, consisting of primitive and transition rocks, are the great depositaries of these mineral treasures.

Iron.

Iron is found in all the chains of mountains in Europe. The richest mines are in the Dofrines, or Scandinavian Alps. But rich mines are also found in the Alps of Stiria, Carinthia, and Bavaria; in the Pyrenees, the Vosges, the Cevennes, the coal district of Britain, the Urals, the Carpathians, the Hartz, and many other places.

Copper.

Copper is also widely distributed, though less abundant than iron. The richest mines are in Hungary, in the Carpathian Mountains. It abounds also in the Saxon and Bohemian mountains, in the Dofrines, the Urals, the north of England, and the Alps; and it is found in the Vosges, the Pyrenees, and other mountains of Spain, in the north of Germany, and in Tuscany.

Lead.

Lead exists in the Alps, Carpathians, Pyrenees, Cevennes, Vosges, the British mountains, and the Uralian chain.

Tin.

Tin is found only in a few places in Europe. The richest mines are in Cornwall; next to these are the mines in the Erzgebirge. It is also found in Hungary and Spanish Gallicia.

Mercury.

Mercury, like tin, is confined to a few places. The mines of Idria, in Austria, which yield 8000 to 10,000 quintals per annum, are the most productive in Europe. There are also considerable mines at Deux Ponts, in the Palatinate; in the Spanish province of La Mancha; and in Transylvania.

Gold.

Gold is widely diffused through Europe, but generally in such quantities as not to repay the expense of working. It is wrought, however, in the Carpathians, the Urals, the Dofrines, and the Alps. Anciently there were rich mines of gold in Spain and Greece.

Silver.

Silver is more abundant than gold, though less widely distributed. There are productive mines of this metal in the Erzgebirge, the Carpathians, the Urals, the Norwegian Dofrines, and in Sardinia. It is found also in the Alps, the Vosges, and the Sierra Morena.

Coal.

Of coal, the richest mines are found in the north and west of England. It abounds also on both sides of the south of Scotland; in Ireland; in the Netherlands; in one fourth part of the French territory; and occurs more sparingly in Saxony, Hanover, Denmark, Sweden, Russia, Hungary, Bohemia, Moravia, Silesia, Bavaria, Austria, Franconia, Westphalia, Swabia, Catalonia, and some other parts of Spain, in Portugal, and in Sardinia. After Britain, France is the country in Europe best supplied with this mineral. The produce of the French coal mines has increased fourfold within the last forty years.

Salt.

Salt is procured from the waters of the ocean, and, in the interior of Europe, from numerous salt mines and salt springs. The most productive salt mines in Europe are those in Poland, on the north side of the Carpathians, and those in Salzburg, on the north side of the Alps, both of which belong to Austria. There are also extensive depositaries of mineral salt in Transylvania and Hungary; in Valentia, Navarre, and Catalonia, in Spain; in Cheshire in England; and in Bavaria and Switzerland. Salt springs are numerous along the sides of primitive mountains in most countries of Europe. The most extensive salt mines of Russia are in Asia.

Antimony, cobalt, zinc, manganese, sulphur, alum, and a great variety of other mineral productions, are found in Europe; but it is unnecessary to specify their localities.

It is observed that the Alps, Pyrenees, Carpathians, and other mountain chains which run east and west, are richest in metals on the south side; while the Dofrines, Urals, and others which run north and south, are richest on the east side. Of the mountain chains of Europe, the Appennines are the poorest in metals, the Carpathians probably the richest.

Different races of inhabitants.

The present population of Europe is sprung from a variety of tribes; but authors differ much as to the number and peculiar characters of the original races. It would serve little purpose to enumerate the contradictory hypotheses which have been advanced on this subject. We shall therefore confine ourselves to an account of those more obvious general characters, founded on language, manners, or physical constitution, which distinguish the different portions of the population of Europe at present.

The nations in the south-west of Europe, the French, Italians, and Spaniards, speak languages in which the Latin idiom predominates. They have generally black hair and black eyes, and are rather inferior in stature to the Gothic nations, but gifted with more imagination and a higher degree of organic sensibility; they are more temperate, more inventive, but less persevering.

The Gothic race includes the English, Swedes, Norwegians, Danes, Netherlanders, and the various German nations inhabiting the country between the Rhine and the Oder, with the Swiss, Bavarians, and a part of the inhabitants of Bohemia, Moravia, and Austria. These nations are distinguished by fair hair, blue or grey eyes, large stature, and a clear complexion. They have less imagination than the southern nations, are more addicted to pursuits that exercise the understanding, are more thoughtful and serious, and less temperate in drinking.

The Sclavonic nations occupy the east of Europe generally, including Russia, Moldavia, Poland, ancient Prussia, with the greater part of Silesia, Hungary, Moravia, Bohemia, Croatia, and Sclavonia. They are rather lower in stature than the Gothic race, the countenance is shorter but more animated, and the hair black. The prevailing religion is the Greek Christian, and in the western parts the Roman Catholic. They all speak dialects of the Sclavonic language, of which the Russian is one.

The remains of the Celtic tribes are found in the Highlands of Scotland, in Wales, Ireland, Bretagne, and Biscay in Spain. They are rather low in stature, have lively eyes, prominent cheek-bones, red or yellow hair in the north, but sometimes black hair in the south.

The Finns, with the Esthonians, Karelians, and other tribes in the north of Europe, have a language of their own, and the characters of a peculiar race. They have light brown eyes, a pale complexion, cheeks hollow, are of middling stature, but heavy and muscular.

The Samoieds, Laplanders, and other tribes who live within the polar circle, are distinguished by their very low stature, the smallness of the legs and feet, and largeness of the head, prominent cheek-bones, small round black eyes, black and bristly hair, and a swarthy skin. The Laplanders, from intermixture with the Finns, Russians, and Norwegians, have lost in some degree the characteristic traits of the original race.

The modern Greeks and Albanians are supposed to be descended chiefly from the ancient inhabitants of the country, whose language they have preserved. They have a greater resemblance to the Latin nations than to those of the Gothic race. The Turks are an Asiatic tribe.[1]

Prog s
of ci za-
tion

Europe has been gradually advancing from poverty and barbarism to wealth and refinement since the tenth century; but the progress of the different nations has been very unequal. No single cause has contributed so much to their improvement as commerce; and hence the first advances have always been made by maritime states; and the progress of the different communities has been nearly in proportion to their vicinity to the sea, or the facility of their communication with it. The small republics of Italy and the Hanse Towns were the seats of industry, wealth, knowledge, and freedom; while slavery, ignorance, and rapine, reigned in the countries around them. The tendency of commerce to enrich a country seems to depend on its power to create disposable capital. Though a certain species of opulence exists among the great landholders of agricultural countries, those masses of disposable capital which give vigour to industry, and supply the means of great improvements, are only found in commercial states. Commerce also favours the growth of manufactures, and these two species of industry raise up a middle class, closely allied with the great body of the people. It is among this class that ideas of civil and religious liberty take their rise, and find their firmest supporters; whereas in countries entirely agricultural, liberty means only the domination of the aristocracy. The spirit of liberty once introduced, laws are improved, prejudices hostile to industry extinguished, and new vigour infused into every branch of society. It is thus that freedom and wealth have generally followed in the train of commerce; and that the commercial states have led the way in those improvements which have so much ameliorated the condition of Europe. When the Italian republics flourished, however, Europe was not in a state to be much benefited by the lights their experience afforded. The Dutch republic, which flourished at a later period, gave a more striking demonstration of the advantages of industry, freedom, toleration, and good government, at a time when neither liberty nor toleration were understood even in England, and when industry was in a very low state all over Europe. The example of the Dutch furnished statesmen with new ideas, and had a sensible influence on the policy of England, France, and other countries. The genius of Peter the Great derived from this small republic the seeds of those improvements by which civilization was spread over the vast empire of Russia. The superiority which the Dutch possessed has since been transferred to Britain, and she has acquired with it the privilege of instructing other nations in the sources of public wealth and the science of government.

---

[1] Adrien Balbi thus classifies the population of Europe into families: 1. The Iberian or Basque family, in Northern Spain and Southern France; 2. The Celtic family, embracing the Scotch Highlanders, the Welsh, and the Bas-Bretons; 3. The Thraco-Pelasgique, or Greco-Latin family, embracing the Albanians, Greeks, Italians, Wallachians, part of the inhabitants of France and Spain; 4. The Germanic family, comprehending the Germans, Netherlanders, Danes, Swedes, English and Lowland Scots; 5. The Sclavonic family, comprehending the Russians, Poles, Wends, Bohemians, Illyrians, Lithuanians; 6. The Uralian family, including the Finns, Tchoudes, Laplanders, and Magyars of Hungary; 7. The Samoieds. (*Abrégé de la Géographie*, p. 103. Paris, 1833.

The Reformation had a material effect in accelerating the progress of society. It put an end to a multitude of abuses and prejudices adverse to improvement, and inspired the human mind with a new activity. Those countries in which it took no root seemed to have had their progress arrested; while others, less favoured by nature, derived new life and vigour from its influence. Italy and Spain, now so far behind Britain, France, and Germany, were the first countries in Europe for knowledge, wealth, and industry, at the period of the Reformation. The establishment of the Protestant religion has produced a more liberal spirit among the Catholics in those countries where the two churches exist together; but in those countries where Protestantism has never obtained a footing, the dread of its introduction has thrown the government more and more into the hands of the clergy; the clergy, armed with power, have become more jealous and intolerant, and have nearly put an end to all freedom of thought. The literary glory of Spain expired some time after the Reformation; and Italy has been checked in her career. The older writers of these countries breathe a spirit which would not be tolerated at the present day, nor does society there afford the elements out of which such characters could be formed. And thus it happened that the very same event which called forth the powers of the human mind in the north of Europe, extinguished the intellectual activity of the south.

The improved means of internal communication in countries in modern times have had a considerable effect upon the state of society. In ancient times free states were necessarily small, because when neither the press nor the post existed, that union of sentiment necessary to control the conduct of men in power could not be effected among a large population scattered over a wide space. A number of free states sprung up in Greece, because that country, perforated by mountains and arms of the sea, afforded natural means of defence to such small societies as could then exercise the functions necessary to the preservation of freedom. It is a mistake to suppose that, in these states, a greater extent of territory could have been united under one government by adopting the representative system. The resolutions of a body of representatives would command no more respect from a government than those of as many private individuals, if they were not constantly supported by the opinions of the mass of society; and this requires such a rapid and general circulation of intelligence as could not then exist. The small size of the Grecian states was a necessary condition of their freedom; but it was a serious disadvantage, not only because it lessened the commercial intercourse between the different parts of the country, but because such small communities had not strength enough to resist a great force from without; and hence these states fell a prey to the superior power of the Macedonian monarchy. The whole of the south-west of Europe exhibits the physical features of Greece upon a larger scale. Its surface is broken into numerous sections by gulfs and mountains, and abounds in natural barriers. Favoured by these circumstances, the different communities in this quarter of the world in modern times enjoyed a certain degree of independence and security, which hastened their progress in civilization. Russia, which occupies the only large plain in Europe, has been the last reclaimed from barbarism. So long, however, as the means of communication remained very imperfect in modern Europe, free governments were confined to small states, and the larger states were abandoned to feudal tyranny or military despotism; but the science of government has gradually improved, as knowledge, commerce, and the arts have advanced; and at present the admirable inventions of the post and the press give such an electric rapidity to the circulation of public sentiment, that twenty millions of men could be as easily united in defence of their rights as the small population of Attica in the time of Xerxes.

The progress of improvement tends to level all distinctions between states, but those founded on the extent of their natural resources. Capital, skill, intelligence, and all acquired advantages, tend to an equilibrium. When Europe was overrun with barbarism, the city of Venice, by its commercial wealth, was a counterpoise to two or three of the great monarchies of the continent. The discovery of America, and of a passage by sea to the East Indies, gave a new direction to commerce, and undermined the greatness of that city. The Dutch republic rose by its freedom and industry, and was able, in the time of Charles II. to dispute the empire of the sea with the combined powers of England and France. But England increased her commerce, and improved her constitution; and having a larger and more fertile territory, as well as a greater population, she at length obtained an ascendancy over Holland, deprived her of the empire of the sea, and stript her of most of her colonies. At the beginning of the seventeenth century, Spain and Turkey were the first powers in the west and east of Europe, and inspired their neighbours with the dread of conquest. Sweden ruled with undisputed sway in the north; and Russia, now so formidable, was scarcely known. Spain, under a better government, might recover a part of her influence; but the Turkish empire seems near its dissolution; and the importance of Sweden and Holland is gone irretrievably, in consequence of the growing strength of the neighbouring powers. The extent of territory and immense natural resources of Russia must, in the end, raise her to a decided superiority over all the other powers of Europe, if the empire does not fall to pieces from its own weight, or get into disorder from the vices of its government. Its progress hitherto has been greatly aided by the personal characters of its sovereigns. If we were to judge merely from the advantages which different states possess for raising and supporting population, we might predict that, in the course of a century and a half, Russia would rule with uncontrolled sway over the old continent, and the United States over the new; and that the other states, which now figure in the first rank in either hemisphere, would then owe their existence, like the small principalities of Europe at the present day, to the forbearance or the mutual jealousy of their powerful neighbours. But in the course of events, many changes may occur to give a different destiny to both continents.

Number of inhabitants.

The number of the inhabitants of Europe has been progressively increasing, slowly in the earlier part of the century, but more rapidly as we approach the present times. Apparently it has been least considerable in Spain, Italy, Sweden, France, and Germany; greater in Russia, Austria, and the British isles; and greatest in Prussia. In 1787, Zimmermann estimated the population of Europe at 144,000,000; and in 1833, according to Balbi, it was 227,000,000. The increase of 83,000,000 in forty-six years implies an annual augmentation of 994 upon 100,000, or very nearly one per cent.; and if this ratio were constant, the population of Europe would double itself in seventy years and a half. In 1827 Baron Dupin estimated the increase in the principal states of Europe to be as follows.[1]

	Annual Increase on one Million.	Period of doubling.
Prussia	27,027	26
Britain	16,667	42
Netherlands	12,372	56½
Two Sicilies	11,111	63
Russia	10,527	66
Austria	10,114	69
France	6,536	105

A comparison of the census for 1821 and 1831, the only two which include Ireland, shows that Dupin's estimate for Britain is too high. The annual increment for the three kingdoms scarcely exceeds one seventy-fifth part, or 13,400 upon a million. The increase in Prussia has been so very rapid, we presume, only since the peace in 1815. The most obvious cause of this increase of population is the increase of production, from the improvement of agriculture and the arts; but part of the effect may be ascribed to the general introduction of potatoes in many countries, by which the same portion of ground is made to support three or four times as many persons as it would under corn. In France, where Mr Young, in 1789, found the cultivation of potatoes extremely limited, it was so much extended in 1819, that, according to Chaptal, the annual produce was nearly 20,000,000 hectolitres, or 55,000,000 bushels; a quantity fully as great in proportion to the population as Mr Colquhoun assigns to Britain and Ireland. This augmentation of numbers does not appear to have been accompanied with any deterioration in the habits of the people. On the contrary, the diminution in the rate of mortality which has taken place in Britain, France, and Sweden, is a decisive proof of an improvement in the condition of these countries; and, by analogy, we may extend the same conclusion to the other parts of Europe. It may be remarked, that the general extension of commerce, and the accumulation of capital, render a season of scarcity, in a particular country, much less destructive now than formerly. In Britain, whose commerce and capital enable her to draw supplies from all parts of the world, the additional mortality, in the most severe scarcity, does not exceed one tenth; but in Sweden, a poor country, it sometimes amounts to one third. (Milne's *Annuities*, p. 400.) In ancient times, when each country depended entirely on its own produce, the effects of a scarcity were dreadful.

Number of states, and their comparative importance.

The states of Europe at present are 62 in number, and, considered with respect to political importance, may be divided into four classes. Britain, France, Russia, Austria, and Prussia, belong to the first; Spain, Sweden, Turkey, to the second; Holland, Belgium, Portugal, Naples, Bavaria, Sardinia, Denmark, Saxony, Wirtemberg, Hanover, and Switzerland, to the third; Baden, Tuscany, and the States of the Church, with the other small states of Germany and Italy, belong to the fourth class. Objections may be made to this classification, but we have not been able to find a better; and a few remarks will explain the principle on which it is founded. The first five powers are the only powers that exercise a decided influence over their neighbours; and it is by their joint counsels that differences among the smaller powers are adjusted, and all questions that concern the general state of Europe decided. The three states of the second class visibly occupy a lower place in the scale of power than those of the first. They have very little exterior influence, but they are not directly controlled by any of the stronger powers; and it is only among them and the states of the first class that wars are now likely to originate. The third class includes those states which are too feeble, and too much under the influence of the great powers, to become principals in war, but are of importance enough to be valued as auxiliaries by states of the first and second classes. The fourth class consists of states which have too little force to maintain any degree of independence, and owe their existence to the justice, the forbearance, or the mutual jealousies of the stronger powers. It is only in Europe that small states exist among large ones; and their existence is the consequence of that equality of power among the great states, which compels each to respect the rights of the others, and to pay a certain degree of deference to public opinion.

A detailed account of the principal European states is given under the proper heads, in their alphabetical order. Our object here is only to bring together such general facts as will afford a comparative view of the internal condition, power, and resources of those larger societies which comprise the greatest part of the population of Europe. With respect to the smaller states, we cannot make room for any further details than what are contained in the table which forms the conclusion of this article.

BRITAIN.

Though much smaller in extent than any of the other states of the first rank, Britain is the most wealthy and powerful of the whole. She has a moderately good climate, a soil less fertile in grain than that of France, but affording better pasturage; an extensive line of sea-coast, with numerous harbours; a natural and well-defined frontier, a good commercial position, and the largest fields of coal in Europe. But all these advantages have contributed less to her aggrandisement than the excellence of her laws and constitution. The progress of Britain in commerce, manufactures, and agriculture, within the last century, and especially within the last forty years, has been wonderfully great.

The British isles contain about 76,000,000 of acres, of which about 49,000,000 are in cultivation, and 27,000,000, or more than one third, waste or uncultivated. About one half of the waste land is in Scotland, where the cultivated soil forms only twenty-six parts in the 100 of the whole surface of the country; in England it forms eighty-two parts in the 100, and in Ireland sixty-nine.[2] The agriculture of Britain, compared with that of the continent, is distinguished by the farms being generally larger, the plan of cultivation more systematic and skilful, the produce on equal soils greater, the pasture land bearing a higher proportion to the land in tillage, and the breed of animals being superior. In Scotland the pasture land forms about one half of the land in cultivation; in England, four sevenths. The whole annual produce of grain in Britain and Ireland was estimated by Dr Colquhoun in 1812 at 35,000,000 of quarters, excluding seed; of which wheat is supposed to form twenty-six parts in the 100 in quantity, barley seventeen parts, oats forty-nine, rye two, peas and beans five. The value of the annual produce of grain was computed by the same author at L.73,700,000;

[2] Colquhoun's *Treatise on the Wealth, Power, and Resources of the British Empire*, 1815, p. 56, 57; Sir J. Sinclair, *General Report of the Agricultural State of Scotland*, vol. iii. addenda.

that of the pasture land at L.89,200,000; and the whole gross produce of all the branches of agriculture, including gardens and cattle, at L.216,000,000. But as this estimate was made in 1812, when prices were uncommonly high, a third or a fourth should be deducted for the present value. The valued rack-rent of England and Wales, as returned to parliament by the commissioners of taxes in 1810, was L.29,503,073, which gives 15s. 6d. as the average of rent of all kinds of land per acre. The rental of Scotland in 1813, according to Sir John Sinclair, was L.5,041,779, including mines and fisheries; and deducting L.341,000 for these, the rent of land would be L.4,700,000, or 4s. 11d. per acre on an average.

The progress of Britain in manufactures has been still more rapid, within a recent period, than in agriculture; and her natural advantages for this species of industry are perhaps more exclusive. She has a good supply within herself of the raw material for all her staple manufactures except cotton; and her means of procuring this article are at least equal to those of her neighbours. The growth of this manufacture in Britain has been unprecedentedly rapid. In 1767, the value of all the cotton goods manufactured did not exceed L.200,000, and in 1832 it was estimated at L.36,000,000. The produce of the woollen manufactures, in the same year, including the raw material, was estimated at L.22,000,000; that of leather at L.10,000,000; of linen at L.12,500,000. (M'Culloch's *Commercial Dictionary*, 1832.)

The commerce of Britain seems to have increased pretty regularly during the first sixty years of the last century; but from 1760 to 1786 it remained almost stationary. From this period to the present time the increase has been rapid beyond example. The exports of England, about 1700, were L.6,045,000; in 1760, L.14,694,000; in 1786, L.15,385,000. (Chalmers' *Hist. View.* p. 315.) In 1832, the official value of the exports was L.76,071,000, of the imports L.44,586,000. The mercantile tonnage in 1832 was 2,618,000 tons, and the number of seamen 161,600. (*Parliamentary Papers.*) The annual produce of foreign commerce, or the sums derived from it by all classes concerned in it, were estimated, in 1812, at L.46,373,478; the gains from inland trade at L.31,500,000; and the whole annual produce of industry, from all sources, at L. 430,000,000 (Colquhoun, p. 96–100); an estimate which is certainly exaggerated.

The growing wealth of Britain has had to sustain an increasing weight of public burdens. The public revenue of England, at the Union in 1709, was L.5,691,803; of Scotland, L.160,000. In 1763 (a year of peace) the net revenue was L.9,100,000; in 1790 L.15,986,068; and in 1812 it was L.64,979,960, of which England furnished L.55,995,123, Scotland L.4,155,599, and Ireland L.4,882,264. (Colquhoun, p. 262.) In the year 1832, the net produce of the revenue was L.51,474,000, which was collected at an expense of L.6. 13s. 11d. per cent. The nominal amount of the public debt at 5th January 1833 was L.754,000,000, the interest L.27,703,000. The unfunded debt was L.35,373,000. The army in 1832 consisted of 95,800 men, exclusive of 17,200 in India. The number of men voted for the navy was 27,000. (*Parliamentary Papers.*)

The population of England appears to have doubled in the hundred years ending 1811; that of Scotland appears to have increased one half in the same period; that of Ireland has also increased very rapidly. In the period between 1801 and 1831, the rate of increase in England and Scotland was such as would have doubled the population in forty-six years. This rapid increase of numbers appears not to have been accompanied with any deterioration of condition. In the five years ending 1784, the annual mortality in England and Wales was one in thirty-seven; in the five years ending 1810, it was one in 47·86. Of the population of Britain and Ireland, about thirty-five families in the hundred are employed in agriculture, forty-five in trades, manufactures, and handicrafts, and twenty in other occupations. The total population of Britain and Ireland in 1831 was 24,304,000. To these must be added about 98,000,000 in the colonies, making a total of 122,000,000.

FRANCE.

This country enjoys, upon the whole, greater natural advantages than any other in Europe. Her territory is above one half larger than Great Britain and Ireland, and is superior in soil and climate. She has a greater proportion of arable land than any of her neighbours; the natural means of communication between her provinces are abundant and easy; she is well provided with all the useful metals except tin; and is better supplied with coal than any other country in Europe except Britain. When we add to these advantages the intelligence and activity of her population, and consider that corvees, tithes, feudal services, and most of those abuses which shackled her industry, are now removed; that she is likely to enjoy the benefits of good laws and a free constitution, and is not encumbered with a great national debt; we cannot doubt that, if peace continue for any considerable length of time, she will yet rise to a much higher degree of wealth and prosperity than she ever before possessed. Even during the distractions of the Revolution, though her commerce was annihilated, her agriculture and manufactures extended and improved, her population increased, and its condition was ameliorated. The greatest bar to her progress will probably be the extreme division of property; and, for some time also, the want of capital.

The surface of France contains within its present limits 52,000,000 hectares, or 128,000,000 acres. From partial surveys, for fiscal purposes, made in each department, it is estimated that the waste land, including roads and rivers, amounts to one eighth of this, or twelve parts in the hundred; the arable land to forty-four parts in the hundred; the woodland to fourteen parts; the pasturage land and meadows to fourteen; the vineyards to four; wild land seven; quarries, buildings, orchards, gardens, olive and other plantations, make up the remaining five parts. (Chaptal, *De l'Industrie Française*, i. 205. Paris, 1819.) In addition to the vegetable productions that grow in England, the climate of France enables her to raise maize, vines, olives, mulberries, and chestnuts; and by some of these a produce is extracted from soil which in England would yield nothing. The whole produce of grain in France is estimated by Chaptal at 143,000,000 hectolitres, equal to 50,000,000 quarters, or 40,000,000 deducting one fifth for seed, which is only 5,000,000 above the produce of Britain and Ireland, as estimated by Colquhoun. Of this produce of grain, wheat forms thirty-six parts in the hundred, rye twenty-one parts, maize four and a half, buckwheat six, barley nine, oats twenty-two, legumes one. The quantity of potatoes (19,800,741 hectolitres) is equal to two thirds of the rye. The produce of 4,000,000 of acres planted with vines, in 1808, was 37,600,000 hectolitres of wine. (i. 173,177.) The *annual gross produce* of the land, which was estimated by Arthur Young at L.230,000,000 sterling, is estimated by Chaptal at 4,678,000,000 francs, or L.187,000,000 sterling,[1] of which the principal items are,

---

Corn and legumes (secs),	L.77,172,000
Vines	28,757,000
Forage	27,322,000
Wool	3,253,000
Raw silk	617,000
Hemp	1,237,000
Flax	760,000
Woods and forests	5,657,000
Cattle, sheep, and swine	17,880,000
Poultry	2,588,000
Fruits	2,584,000
Pulse and other esculent vegetables (legumes frais)	7,872,000

(Chaptal, i. 226–238; Young, i. 468).

Revenue imposable.

The mean revenue derived from a hectare of land is estimated by Dupin at thirty and a half francs, or 25s. 5d. equal to about 10s. 3d. per acre; and the revenue of the whole departments, calculated on this basis, is L.65,000,000. The last sum includes houses, and may be considered as corresponding nearly to the rack-rent of lands and buildings in France. This is certainly too low. The average rent of all kinds of land in France was estimated by Young at 15s. 10d. per acre. (*Trav.* i. 476.) The most peculiar feature in French agriculture is the vast number of small proprietors, who cultivate their patches of land by their own labour. Arthur Young supposed that, before the Revolution, one third of the property of the kingdom was held by such persons; and Chaptal says the number of proprietors is doubled within the last thirty years. The latter computes the whole number of farms in France at 3,000,000; so that, on an average, each cannot exceed forty-three acres, including wastes. In the cultivation of good soils, the agriculture of France is nearly equal to that of England; but it is greatly inferior in the management of poor soils, in the system of cropping, and in the breed of animals. It has been much improved, however, during the Revolution, by the extensive cultivation of artificial grasses, by augmenting the live stock, by the general exclusion of fallows, and by increasing the cultivation of potatoes.[1]

The manufactures of France, amidst all the troubles of the Revolution, have been generally advancing, though some branches have retrograded. The number of workmen employed in Lyons, the principal seat of the silk manufacture, was one fourth greater in 1812 than in 1789. France produces within herself about eleven millions of pounds of raw silk, and imports nearly as much; and the total value of the manufactured articles produced is estimated at L.4,300,000. Of wool, France produces about ninety-three millions of pounds, valued at L.3,253,000, and imports seventeen millions of pounds, which, converted into various fabrics, is estimated to be worth L.9,500,000 sterling. The value of the manufactures of flax and hemp is estimated at L.9,612,000. The spinning of cotton by machinery, which was scarcely introduced before the Revolution, employed one million of spindles in 1812; in that year there were 23,000,000 pounds of cotton spun; in 1825 there were 62,000,000. The value of the cotton goods manufactured is estimated at L.7,600,000. The manufactures of iron in France are estimated at L.8,300,000; those of leather at L.5,700,000. The whole gross produce of manufacturing industry, including manufacturers' profits, is estimated at 1,802,000,000 of francs, or L.72,800,000, of which the value of the raw material forms thirty-two parts in the hundred, wages forty-seven, manufacturers' profits ten, and expenses eleven. (Chaptal, ii. 116, 203; Dupin, tom. i.)

The exports of France in the year 1827 amounted in value to 602,000,000 francs (L.24,000,000); the imports to 565,000,000 (L.22,600,000). The leading articles of exportation were silk goods, raw silk, cottons, linens, wines, and woollens; the leading imports were raw silk, cotton, linen, and coffee.

The population of France, notwithstanding the interruption to industry, and the drains occasioned by the long wars, has increased since the commencement of the Revolution. According to calculations made by the National Assembly in 1791, France contained 26,363,074 inhabitants, and in 1831 it contained 32,560,000 within the same limits. (*Annuaire pour l'An* 1834). The annual increase is about 200,000 individuals. The condition of the labouring classes appears to be improved. Wages, which Arthur Young estimated at 19 sous, or 10d. English per day, throughout the kingdom, for all kinds of work, were estimated at 1s. 2d. by Dupin, in 1827. The annual mortality, which was estimated at one in thirty by Neckar before the Revolution, we find stated recently to be one in forty. (*Annuaire pour* 1834.)

According to returns made in 1815, there were then in France 22,300 primary schools, with 737,379 pupils. There were, besides, 368 secondary schools, thirty-six lycees, and twenty-six universities. In 1833 there were 44,500 primary schools, which were attended by 1,907,000 pupils of both sexes.

The ordinary revenue of France, in the year 1831, was 973,000,000 francs, or L.39,000,000. The debt was 5,400,000,000, or L.216,000,000, and the annual interest 283,000,000, or L.11,300,000. There are about 40,000 parish priests in France, whose pay, with that of the bishops, amounts to L.1,200,000.

From the commencement of the Revolution to 1810, France received great accessions of territory. The peace of Luneville left her in possession, in whole or in part, of the Austrian and Dutch Netherlands, the bishoprics of Liege, Cologne, Trèves, Mentz, duchy of Juliers, the Palatinate, Mœurs, Guelders, the department of Mont Blanc, Leman, Maritime Alps, with the Venaissain, Montbeliard, and other *enclavés*. These various districts comprehended a surface of 27,400 square miles, and a population of 5,025,000.

Between 1801 and 1810 she acquired Piedmont, Genoa, Tuscany, Parma, the Roman States, the Valais, the Illyrian provinces, with Venetian Dalmatia; Holland, Bremen, Hamburg, Lubec, Munster, Osnaburg, and part of Hanover. These districts comprehended a surface of 110,000 square miles, and a population of 16,057,000. With these additions the French empire, in 1812, included an area of 310,000 square miles, and a population of 44,500,000.

If to these we add the states dependent upon France; namely, the Cisalpine Republic, 31,000 square miles, with 6,350,000 inhabitants; the Confederation of the Rhine, 113,000 square miles, with 14,000,000 inhabitants; and Naples, 30,500 square miles, with 4,960,000 inhabitants; we have an aggregate of 486,000 square miles, and a population of nearly 70,000,000. The kings, princes, or chiefs of these dependent states, were in reality nothing more than Napoleon's viceroys; and it may be said with truth, that in 1812 the resources of the vast population of seventy millions now enumerated were at his disposal.

By the peace of Paris in 1815, France was stript of all her conquests, and reduced within her ancient limits, as they stood in 1789, with some inconsiderable variations, not sensibly affecting her whole extent of territory, or amount of population.

---

AUSTRIA.

The Austrian empire is one fourth larger than France, and twice as large as Britain and Ireland. Its population consists of a mixed mass of nations, differing in origin, language, religion, and manners, having few common ties, and little intercourse with one another. Austria has but a small extent of sea-coast, and is almost entirely an inland power. The climate is similar to that of France, but subject to greater extremes of heat and cold, the soil not much inferior, the grain and fruits nearly the same. She is richer in mineral wealth than any other state in Europe, and possesses coal, though not in great abundance. Her natural resources are capable of vast improvement; and in the hands of a wise and liberal government, would soon raise her far above the rank she now enjoys. Of the six sections into which her territories are divided, Lombardy is the most populous in proportion to its extent; Bohemia and Moravia are next in population, and are the seats of the chief manufacturers; Austria Proper and Hungary are remarkably rich in mines; and Galicia, though in a low state of cultivation, is fertile in grain, and contains the most productive mines of salt in Europe. Austria has but a slender title to be regarded as a German power; less than one fifth of her population are Germans. The Sclavonic race, who form nearly one half of the population, give a character of ignorance and backwardness to the government. In Bohemia, Hungary, and other provinces where this race predominates, vassalage exists in some of its forms, and cramps the progress of society. The Austrian empire, in truth, consists properly of six separate governments, feebly united under one head. Each of these governments, except that of Lombardy, has a diet or states, composed of the deputies from the nobility, clergy, and towns; but these bodies exercise no real influence over the government, except in Hungary, where the old feudal institutions remain in vigour, and the aristocracy have always maintained a great degree of independence.

The surface of the Austrian monarchy is estimated at 258,000 square English miles. Of this surface, the waste lands, including morasses, mountains, rivers, and ground covered with buildings, are estimated at five parts in twenty-four, the useful soil at nineteen parts in twenty-four; and of the useful soil about forty-three parts in the hundred are in tillage, nine parts meadow land, nine parts commons, which support cattle, two parts vineyards, two parts gardens and orchards, and thirty-five parts forest land. The total produce of grain is estimated at 165,500,000 metzen, or about 35,670,000 quarters, consisting of wheat fourteen parts, barley eleven, rye thirty-one, and oats forty-four. In 1804 the net produce of a joch (equal to one acre and a half) of corn land, for the whole Austrian states, was valued by Lichtenstern at five florins (10s.), and of pasture land at two florins (4s.) (Hassel's *Stat. abris des Oest.* p. 90.) The annual produce of wine in the Austrian dominions is estimated at from 36,000,000 to 40,000,000 of eimers (each equal to fourteen English gallons), of which Hungary furnishes nearly two thirds. This is rather more than one half of the produce of the French vineyards. Galicia is the only province in which there are no vines. Hungary and Sclavonia supply 180,000 centners of excellent tobacco. The Ex-Venetian states furnish yearly 1,200,000 pounds of silk; Milan and the Tyrol nearly as much; and altogether this species of culture employs 400,000 persons. Flax, hemp, hops, and fruits, are also extensively cultivated; and the forests, which cover more than one fourth of the empire, furnish an ample supply of wood. The total produce of the vegetable kingdom is valued at 68,500,000 sterling, a small amount, considering the extent of the country; but agriculture, though there are numerous societies for its improvement, remains in a low state, from the prejudices of the higher classes, and the oppressions to which the peasantry are exposed. The horses in the empire are estimated at 1,800,000, the sheep at 12,000,000, and the horned cattle at 10,000,000. The live stock has greatly diminished within the last twenty-five years. The annual produce of the mines is 3846 marks of gold (the mark is about three fourths of a pound Troy); 486 centners (hundredweights) of silver, 56,000 centners of copper, 30,000 centners of lead, 4890 centners of tin, 1,200,000 centners of iron, and 5300 centners of mercury. About 5,500,000 centners of salt are prepared, the greatest part from salt mines and springs. The annual produce of these minerals in 1802, when it was probably one third less than the above, was valued at L.4,700,000.[1]

The leading manufactures are linen, cotton, woollen, silk, leather, and works in metal and wood. The linen manufacture existing in all the provinces, but to the greatest extent in Bohemia and Moravia, is supposed to employ 1,200,000 persons; the woollen manufacture 300,000 persons; the cotton 100,000: about 18,000 or 20,000 centners of cotton were spun by machinery in 1817, which is three times the quantity spun in 1803. The silk manufacture, which is carried on chiefly in Lombardy, employs 110,000 persons. The most considerable manufactures in metal are in Styria, Carinthia, and Lower Austria. The estimate of the annual products of the Austrian manufactures, given by Crome, is too extravagant to deserve any credit. But those of Bohemia, in 1811, were valued at 158,000,000 of florins; and if we add twice as much for all the other states, the whole produce of the Austrian manufactures may, on this ground, be computed at L.47,000,000 sterling. Even this is probably above the truth. (Lichtenstern, p. 44; Crome, 173–176.)

The commerce of Austria is extremely trifling. She possesses but a small extent of sea-coast, which is remote from the centre of her territories, is destitute of navigable rivers, and rendered difficult of access by mountains. The numerous rivers that water her dominions afford few advantages to her trade, as, excepting in Italy, she does not command the outlet of any one of them. The whole exports of this large empire are only L.3,000,000, and the imports L.3,200,000. (Lichtenstern, p. 48.)

The population of the Austrian empire, in 1817, was 28,207,886, of which the Sclavonic race amounted to 13,182,000, the Germans to 5,342,000, the Italians to 4,226,000, the Magyars or Hungarians to 4,225,000, the Wallachians to 1,246,000, and the Jews to 487,000. (Lichtenstern, p. 1858.) In 1832 Balbi estimated the population at 32,000,000. There are, besides, considerable numbers of Greeks, Turks, Albanians, and Armenians; so that, except Russia, no state in Europe has such a heterogeneous population. Throughout the Austrian dominions, the nobility and clergy are numerous, and many of them very rich. In Hungary, Galicia, and indeed in the greater part of the empire, these classes are exempt from taxes, and enjoy other pernicious privileges. The Austrian clergy, exclusive of their families, are estimated at 64,000, of whom 56,000 belong to the Catholic church; the nobles of both sexes at 475,000; the civil servants of the government, with their families, at 280,000; the military, men, women, children, and servants, at 800,000; the burghers and tradesmen, with their families, at 2,333,000; the persons engaged in agriculture at 4,005,000 families, or about 20,025,000 individuals. (Lichtenstern, p. 133.) In all the provinces, especially in Bohemia, Moravia, and Hungary, there has been a rapid increase in the numbers of the inhabitants. Though the people are poor and ignorant, the government has been at much pains to provide them with the means of instruction; and the numerous schools and academies established must essentially contribute to the improvement of the country. The Catholic religion, though it predominates, nowhere enjoys that exclusive ascendancy which produces such pernicious consequences in Spain and Italy. The other sects, Greeks, Calvinists, Lutherans, form nearly one third of the inhabitants in the provinces beyond the Alps; and this circumstance, by generating a certain freedom of thought and discussion, must prove favourable to the progress of society.

Prussia.

Prussia is the smallest in extent, and enjoys the fewest natural advantages, of all the European states of the first class. Her territory is not much more than two fifths of that of Austria; it is but indifferently fertile; has few valuable mines, few resources for manufactures; she has, however, pretty large extent of sea-coast, and a considerable commerce. Her possessions are straggling and disjointed; they present an extensive frontier, with little depth, and no natural barriers; and are inhabited by people who speak different languages, and have few common ties or interests. Prussia has sustained her rank chiefly in consequence of the superiority of her internal organization. Her government, unlike those of the other monarchies of Europe, being of very recent origin, is not encumbered by those ancient establishments which the change of circumstances has converted into abuses. The frame of her public institutions was much improved by the Great Frederick, who availed himself of all the lights and philosophy which the age furnished. He established a complete toleration in matters of religion; curtailed the oppressive privileges of the nobles; simplified the administration of justice; and introduced order and economy into every department of the government. He left the kingdom to his successor with a large and well-disciplined army, and a high reputation for policy and prowess. After the misfortunes in which Prussia was involved by the battle of Jena, the present king, aided by his enlightened minister Hardenberg, began a series of most extensive reforms, which have raised the oppressed peasantry to the rank of free farmers, or independent proprietors, reduced still farther the privileges of the nobles, released trade from the weight of incorporations, and created the most ample means of instruction for the whole population. The population of Prussia, of whom two thirds are Protestants, is more intelligent than that of Austria; includes a greater proportion of Germans; and altogether she is more of a German power. The large rivers that water her territories have generally a very level course; and being joined by canals, they afford a great extent of inland navigation. Of all the old provinces, Silesia is the most industrious and flourishing. It doubled its population in the seventy-three years between 1742 and 1815. The Westphalian and Rhenish provinces are the most populous; ancient Prussia and the Polish provinces the least. (Russell's *Travels in Germany*, 1824, vol. ii. p. 110.)

Agriculture has been greatly extended in Prussia, and somewhat improved in recent times. Besides the common species of grain, tobacco, mulberries, vines, flax, and hemp, are cultivated. Great quantities of potatoes are also raised. Horned cattle and sheep are pretty numerous in most of the provinces. M. Krug estimated the mean rent of an arpent of corn land, for the whole Prussian states, at $2\frac{1}{12}$ rix-dollars (about 7s.), and the *net produce* of an arpent of corn land at two fifths of the gross produce; but of pasture land at one fourth or one fifth only, including poultry and bees. According to returns made from the different provinces to the government, the whole annual produce of grain in Prussia about 1802, when the population was 8,754,000, was 4,500,000 wispel (equal to 9,600,000 quarters); of which wheat formed nine parts in the hundred, rye forty, barley twenty-four, and oats twenty-seven; of this quantity one tenth was exported. The Prussian silver mines yield annually about 20,000 mark of silver; the county of Manifield alone furnishes 14,588 centners of copper; and Silesia affords 7600 centners of lead, and 405,900 centners of iron. The principal manufactures of Prussia are linen, woollen, cotton, silk, leather, iron, and porcelain, all of which are making progress.

In proportion as the other great states of Europe improve their natural resources, the importance of Prussia must decline. The time is past when the good order of her finances, and the discipline of her armies, could raise her to an equality with France, and Austria, and Russia; and she can only now support her rank by cultivating still farther those moral advantages which are the real source of her strength.

In 1791 Prussia acquired the principalities of Anspach and Bayreuth; in 1793 a part of Poland containing 1,136,000 inhabitants; and in 1795 an additional part, containing 860,000. At the peace of Luneville in 1801, she gave up some possessions on the left of the Rhine, and received indemnities in Germany, leaving a balance in her favour. These various acquisitions added 46,000 square miles to her territory, and 2,836,000 to her population, raising the former to 116,000 square miles, and the latter to 9,100,000 souls. Such was Prussia in 1803. The ruinous campaign of 1806 suddenly deprived her of all her possessions between the Elbe and the Rhine, with four fifths of her share of Poland, reducing her territory and population about one half, the latter being estimated at 4,560,000 in 1808. On the overthrow of Napoleon in 1814, she was restored to more than her ancient splendour. She recovered the greater part of her Polish dominions, gained some districts in Saxony and Lusatia, Swedish Pomerania, and an extensive, rich, and populous country in Westphalia and on the Rhine, including the greater part of the secularised ecclesiastical states, abbey lands, &c. The Prussian monarchy at present embraces an area of 94,000 square English miles, and a population of 12,464,000.

Russia.

Russia occupies very nearly one half of the surface of Europe; and yet her territories in this division of the globe are scarcely more than one fifth of her whole dominions. Three fourths of her Asiatic territories, however, consist of sandy deserts or frozen plains, which yield very little for human subsistence; and her possessions in Europe are at present, and perhaps will always be, the most valuable part of the empire. European Russia consists chiefly of an elevated plain, over which numerous rivers flow with a small declivity, so as to afford a greater extent of inland navigation, probably, than exists in all the rest of Europe. Its superficial extent, including Poland, is about 1,990,000 square English miles, which is about ten times the area of France, or sixteen times that of the British isles. But of this surface, more than one fourth part, lying beyond the parallel of 60°, is incapable of cultivation, from the rigour of the climate, or the marshy nature of the soil. In the south, also, there are vast sandy plains, the soil of which, destitute of wood and water, and impregnated with salt, is altogether useless for agriculture. The fertile part of Russia consists chiefly of the country lying between the parallels of 50° and 57°, which contains a great proportion of excellent soil, well watered with navigable streams, and comparatively populous and cultivated. The cultivation of wheat is chiefly confined to this region; and here abundant crops are procured with little labour, and by a very rude species of culture. But farther north slender crops are obtained with so much exertion, that a single peasant cannot cultivate more than from seven to ten acres; and these crops are so precarious, that the rye sometimes will not ripen in the neighbourhood of Petersburg. The lands, however, where corn will not grow yield pasture and wood. Trees are found as far as the sixty-seventh degree, beyond which there are only shrubs.[1]

It has been computed that the soil incapable of cultivation in European Russia amounts to forty parts in the hundred of the whole surface. The crown forests are estimated at 44,500,000 of desiatines, equal to 240,000 square miles. Rye is the grain most extensively cultivated all over Russia; but barley, wheat, and oats, are also raised. In the southern provinces, maize, rice, vines, and even cotton, succeed; and both in the southern and central parts, vast ranges of pasture ground support numerous herds of cattle, the skins and tallow of which, with the peltries of wild animals, are leading articles of exportation. These pastures are generally commons: the quantity of uncultivated lands, says Storch, is so great, that it would be useless to divide them. The number of sheep in Russia has been estimated at 60,000,000. Flax and hemp, however, are the productions in which the soil of Russia has the greatest superiority, and of these she exports great quantities. Some of the less civilized nations are almost supported by bees, and wax and honey are also among the principal articles of exportation. Russia has rich mines of gold, silver, copper, iron, lead, and salt, the best of which are in the Uralian Mountains, and chiefly on the Asiatic side. They employ about half a million of persons.

The manufactures of Russia are inconsiderable, though the government has made great exertions to encourage this species of industry. The principal are those of coarse woollens, flax, iron, leather, silk, glass, and brandies. The manufacturing establishments in 1815 amounted to 3262, of which 181 were for cloth, 150 silk, 1348 leather, 247 soap, tallow, and wax, 184 linen, 295 cotton, 138 glass, 200 metal. (Crome, p. 70.)

If confidence might be put in the lists transmitted to government, the annual mortality in Russia is only one in fifty-eight, the births one in twenty-six, and the annual addition to the population one in forty-nine, so that the period of doubling should be thirty-five years. (Storch, i. 282.) But these extraordinary results are irreconcilable with facts. There are in Russia above eighty nations, who speak more than forty different languages; but the Sclavonic race forms seven eighths of the whole European population. According to the official returns in 1783, the peasants belonging to the crown and to the nobles amounted to eighty-three persons in the hundred of the whole population. (Storch, i. 249.) Of all the powers of Europe, Russia is the only one that, during the numerous changes of the last thirty years, has never lost any part of her territories, but has been continually adding to them. Her acquisitions since 1770 are as follows:

	Square Miles.	Population.
1772, First partition of Poland....	33,000	1,226,000
1793, Second do. do........	90,000	3,745,000
1795, Third do. do........	42,000	1,407,000
1774 to 1791, from the Porte....	60,000	204,000
1807, District of Bialystock from Prussia........................	4,200	183,000
1809, District of Tarnopol, ceded by Austria, containing 400,000 inhabitants, but restored in 1815.		
1809, Finland and Lapmark from Sweden....................	120,000	895,000
1811, Part of Moldavia and Bessarabia from the Porte...........	13,000	230,000
1814, Duchy of Warsaw, now the kingdom of Poland..............	47,400	2,793,000
Total acquisitions of Russia since 1770 in Europe.................	409,600	10,683,000

The success of the Parisian insurrection in July 1830 roused the Poles to make a new effort for independence, which began in November 1830, and was finally crushed in the following year, after a heroic resistance. The consequence was, that Poland was deprived of its separate constitution, and incorporated with Russia as an integral part of the empire in February 1832.

SWEDEN.

Sweden has sunk in her relative importance in consequence of the rise of Russia; but she still holds a higher place in the scale of power than any other European state with an equal population. Now that Norway is united to her dominions, she has the best military and commercial position of all the northern continental powers. But the soil is poor and rocky; so that, though her territories form one tenth of the surface of Europe, her population amounts to less than one fiftieth. Her principal wealth consists in her rich mines of iron and copper, and in the produce of her forests and her fisheries.

The agricultural produce of Sweden, which does not suffice for her own consumption, consists chiefly of rye, oats, barley, and potatoes; the soil and climate not admitting of wheat, except in the southern parts. Gothland, the most fertile province, contains one half of the population upon less than one fifth of the surface of the kingdom. The soil actually under corn cultivation in 1810 amounted only to 1,091,000 tunnas, or 1,363,838 acres; but the soil capable of cultivation was estimated at 1,818,450 acres, or one sixty-second part of the surface of the country. This is the average of the whole; but in the province of Nordland only one acre in 915 is arable. The lakes cover one eighteenth part. The pasture ground and gardens occupy about twice the quantity of land under corn. The average size of a farm is only about twenty-seven acres. The whole annual produce of grain is estimated at 5,702,835 spans, equal to about 1,482,500 quarters, besides 350,000 quarters of potatoes. The general produce of the crops is about five for one. In Norway, the land in cultivation amounts to less than one acre in a hundred, and one fourth of the grain used is imported. Potatoes are extensively cultivated. In times of scarcity bread is made of the bark of trees, and of the Iceland moss, on which the rein-deer feed.

---

[1] Storch, *Tableau*, i. 4; ii. 209, 229, 231; Crome, *Ubersicht*, 55.

The manufactures of Sweden are of little importance. Sixty or seventy ships are built annually, and sold to foreigners. The distillation of brandy consumes 700,000 spans of corn a year. The manufactures of paper and glass, and works in metal, supply the internal consumption; those of cotton, wool, and silk, are of small extent. The whole produce of manufactures in Sweden (exclusive of Norway), in 1814, was valued, in an official statement, at 5,622,129 dollars banco, or about L.800,000. (Crome, 123.)

The exports of Sweden, in 1816, were estimated at seven millions of dollars (exclusive of Norway), and the imports at no less than twenty millions. The supposed national loss arising from this disproportion led to a prohibition of the importation of wine, rum, cotton stuffs, and other articles considered as luxuries. In 1816, Sweden had 1107 merchant ships, whose aggregate burden was 64,000 lasts, or 120,000 tons. (Crome, 122, 125.)

The population of Sweden was estimated at 2,615,800 in 1818; that of Norway, in 1803, was 910,000; and from the probable rate of increase there, must now amount to fully one million. In Sweden about one ninth, and in Norway about one twelfth of the people live in towns. This increase in numbers has been attended with an improvement in the condition of the inhabitants. The annual mortality in Sweden, which Malthus, in 1796, estimated at one in thirty-seven, was, in 1811, according to Akrell, one in forty for the southern parts, one in forty-seven for the northern, and one in forty-three for the whole kingdom. In Norway the mortality has always been smaller than in any other European country. In 1815 the nobles amounted to 1641 families, or 9523 persons; the clergy, including their families, to 15,202; the burghers to 64,755; and the peasants to 1,763,397. Besides these classes, who are represented in the diet, there are about 500,000 persons not represented, consisting of civil and military officers, miners, mechanics, servants, &c. About one fourth of the peasants who are householders, farm their own lands. The established religion is Lutheran, and the number of parochial clergymen in Sweden is 1094, besides 170 prebends, eleven bishops, and one archbishop; and the tithes amount to 283,232 spans, or about 72,500 quarters of corn. Norway has 467 clergymen, including five bishops. (Crome, 96, 116; Thomson's *Travels*, 418.)

Subsequent to the revolution in 1809, some improvements have been made in the constitution, by enlarging the powers of the diet. The four estates of nobles, clergy, burghers, and peasants, who sit in separate houses, meet necessarily at the end of five years, or oftener if convoked by the king. The consent of three of these houses, with that of the king, gives a proposition the force of law. No taxes can be raised without the authority of the diet, and the persons of the members are inviolable during the session. The conscription, which was introduced in 1809, subjects all males between twenty and twenty-five to military service; and the nobles have been deprived of the exemption they formerly enjoyed from this service and from taxes. The press is declared by the constitution to be free, but is in fact under the control of the police.

In 1809, Sweden lost Finland, Lapmark, and Pomerania, containing 1,015,000 inhabitants, upon a surface of 121,000 square miles. In 1813, she gained Norway from Denmark, with 950,000 inhabitants. This acquisition gave her a better frontier and a more compact territory, and was more than a compensation for her previous losses.

SPAIN.

The vast natural resources of this country present a striking contrast with its political imbecility. It is nearly as large as France, but contains little more than a third of the population, though its fertile soil and delicious climate yield in abundance the productions both of the temperate and warm regions of the globe. With its great extent of sea-coast, numerous rivers, and excellent position for trade, and its rich and extensive colonies, nothing but extreme misgovernment could have prevented it from becoming the first commercial state in the world.

In addition to silk, tobacco, vines, olives, and all the agricultural productions of France and Germany, Spain produces the orange, citron, sugar-cane, cork-tree, dates, figs, and cotton. Wheat is the grain most extensively cultivated. Barley and rye are next in quantity. Very few oats or potatoes are raised, but considerable quantities of maize and rice. Hemp to the value of a million of piastres is raised yearly, and flax is cultivated on a smaller scale. The vineyards, besides supplying the internal consumption, furnish 10,000,000 or 11,000,000 gallons of wine for exportation, and half as much brandy. Olive oil is exported to the value of L.600,000 a year. The annual produce of raw silk is valued at L.300,000. But wool is the produce for which Spain is most celebrated. The number of merinos or migratory sheep, which furnish the finest wool, is estimated at 5,000,000; those that are stationary, at 8,000,000; and these 13,000,000 of sheep are supposed to afford yearly 45,000,000 pounds of wool. The right of pasture which the migratory flocks have over whole provinces is one great obstacle to agricultural improvement. From this and other causes, one third or one half of the kingdom is left entirely waste, and the part in cultivation is wretchedly managed. Nearly the whole land in the kingdom is locked up by entails in the hands of the nobles and the clergy, and the small portions brought into the market sell so high as not to afford more than one and a half per cent. upon their price. Agriculture is entirely in the hands of the peasantry, who are poor and ignorant; men of capital never engage in it; and the grandees, who should support and encourage improvements, all reside in the large towns. In the whole of Spain there is scarcely to be seen a villa or gentleman's seat, except a few that are in ruins. The mines of Spain, like her agriculture, are neglected; but she still derives from her own soil a considerable supply of iron, copper, lead, and mercury. About 5,000,000 centners of salt are annually obtained from mines, springs, or the sea.

The greatest number of the Spanish manufactures are in Catalonia, but a few are scattered through the other provinces. The most considerable are the woollen, silk, linen, cotton, hemp, leather, paper, and metal; but none of them are sufficient for the internal consumption of the country, and all of them are fettered by vexatious taxes, absurd regulations, and the difficulty of intercourse between the provinces. The manufacture of tobacco is a royal monopoly.

It is now pretty well ascertained, that the apparent decline of Spain has been the consequence of the rapid progress of her neighbours; and that, down to the end of the eighteenth century, she was advancing both in industry and population. From a combination of circumstances, the causes which check the progress of society have operated more powerfully there than in any other country of Europe except Turkey. Among the greatest evils in the state of the country may be reckoned the excessive number of the nobility and clergy, with their oppressive privileges, and their pernicious influence upon the other classes. In 1788, when the population amounted to

10,500,000, the number of the secular and regular clergy was 147,722, of the nobles 478,716, of peasants and labourers 1,847,010, of manufacturers and handicrafts 302,000, servants 276,090, merchants 34,030.

GERMANY.

In the early part of the eighteenth century, Germany consisted of about three hundred sovereign states, great and small, which were united into one empire by a very complicated constitution. From time to time some of the smaller principalities have been suppressed, and incorporated with the larger states: but the first radical change in the composition of the Germanic body was made by the treaty of Luneville, 9th February 1801, when a vast number of bishoprics, abbeys, and free towns, were deprived of their rights of sovereignty, and given as indemnities to princes who had lost their possessions in Belgium and Italy by the French conquests. In 1806 the emperor Francis formally renounced the dignity of head of the empire; the ancient constitution of the empire was dissolved, and a new league formed, with France at its head (see CONFEDERATION OF THE RHINE), comprehending the most considerable states in the south, to which those in the north were afterwards added. This confederation fell to pieces on the overthrow of the French power in 1813, but it has served as the foundation of the new constitution of the Germanic body. The number of states is now reduced to thirty-nine, including Austria, Prussia, Denmark, and the Netherlands; but these four powers rank as members only for a part of their dominions. The ecclesiastical principalities are entirely abolished; and the free towns, of which there were forty-seven or more in 1800, are now reduced to four. The princes who have lost their sovereignty have been reduced to the rank of nobles, and, no longer holding immediately of the empire, are said to be *mediatised*. The titles of royalty conferred by Bonaparte upon Bavaria, Wirtemberg, and Saxony, have been confirmed, and Hanover has since been raised to the same rank. The common concerns of this confederacy are managed by a diet, consisting of deputies from thirty-eight states (Hesse Homberg having no vote), who meet at Frankfort. The pecuniary contributions, fixed in proportion to the population of each state, are voted for a period of five years. The military contingents, which are regulated on the same principle, amount to 120,000 men in time of peace, and 301,000 in time of war, the latter being at the rate of one in the hundred of the population. The German states, including two sevenths of Austria, four sevenths of Prussia, besides Holstein and Luxemburg, embrace an area of about 237,000 English square miles, with 32,000,000 inhabitants; of whom about one half are Catholics; two fifths Lutherans; the rest Reformed, Moravians, Greeks, and Jews. The new Germanic constitution, though less complicated than the old, can scarcely be expected to produce any of the effects of a solid union in such a heterogeneous mass. The states are too unequal in strength to have a proper reciprocal influence; and there is not weight enough in the minor members to control the rival interests and jealousies of Austria and Prussia. The confederation may be considered as recognising, and in some degree regulating, the influence which the greatest states must necessarily exercise indirectly over the smaller.

The following table exhibits the result of the various changes since the commencement of the French Revolution, upon the principal members of the confederation; but to enter into particulars would carry us beyond the proper limits of this article. Most of them, except Saxony, have been enriched by the breaking up of the ecclesiastical principalities.

	Before the Revolution.		In 1816.	
	Square Miles.	Population.	Square Miles.	Population.
Bavaria	22,000	2,183,000	30,000	3,560,000
Saxony	14,800	2,104,000	7,200	1,200,000
Hanover	10,900	787,000	14,400	1,305,000
Wirtemberg	3,200	608,000	8,200	1,395,463
Baden	1,370	177,000	5,800	1,001,700
Hesse Cassel	3,340	443,500	4,300	540,000
Hesse Darmstadt	2,180	249,700	4,100	619,500
Oldenburg	960	95,000	2,500	217,000

(Hoeck, *Aperçu ;* Hassel, *Europ. Staats*, 1816).

The political arrangement of the states of Europe established by the peace of 1815, has since undergone three material alterations. The Greeks rose in arms against the Porte in 1821, and after a struggle of nine years, the independence of their country was acknowledged by the sultan in February 1830. The new state comprises the Morea, Livadia, Negropont, the Cyclades, with one or two other islands, and contains a population, according to Balbi, of only 600,000 souls. Otho, second son of the king of Bavaria, was appointed king of Greece in 1832.

The mutual antipathy which had long existed between the Dutch and Belgians broke out on the part of the latter into a revolutionary movement, which commenced in Brussels in August 1830, and in a few months spread over all Belgium. The independence of the latter country has since been acknowledged by nearly all the great powers; and Prince Leopold of Saxe Cobourg was chosen king in 1831 by an assembly of the representatives of the people.

The third change has been already noticed, the incorporation of Poland with Russia in February 1832.

The following statistical table of Europe is part of a larger one published at Paris by Adrien Balbi in 1828, under the title of *Balance Politique du Globe.* He has reprinted it in his *Abrégé de la Geographie*, published in 1833, with very few alterations except the insertion of the new states since recognised, namely, Greece and Belgium. It refers to the years 1826–27, his object being not to give the most recent accounts for each state, which must have varied according to the varying dates of our information, but to exhibit the contemporaneous condition of all the states at one common era, for the purpose of comparison. It presents the most correct view of the statistics of Europe within our reach; and what we have mentioned as to the author's mode of compiling it, and his object, will explain the discrepancies between it and some of our previous statements.

States and Titles.	Surface in Square Miles.	Population.	Classification of the Inhabitants according to their Religion.	Revenue in Pounds Sterling.	Debts in Pounds Sterling.	Army.
French Monarchy	205,000	32,000,000	Catholics, Calvinists, Lutherans, Jews	40,784,000	190,680,000	279,900
Empire of Austria	258,000	32,000,000	Catholics, Greeks, Calvinists, Lutherans, Jews, Unitarians, Arminians, &c.	18,600,000	68,206,000	271,400
Prussian Monarchy	107,000	12,464,000	Evangelists (Lutherans, Calvinists), Catholics, Jews, Mennonites, &c.	8,866,000	29,966,000	162,600
Swiss Confederation	14,900	1,980,000	Calvinists, Catholics, Jews	412,000	......	33,759
K. of Bavaria	29,500	4,070,000	Catholics, Evangelists, Jews	3,262,000	9,823,000	35,800
K. of Wirtemberg	7,600	1,520,000	Lutherans, Catholics, Jews, Calvinists	980,000	2,330,000	13,955
K. of Hanover	14,800	1,550,000	Lutherans, Catholics, Calvinists, Jews	1,072,000	2,640,000	13,054
K. of Saxony	5,780	1,400,000	Lutherans, Catholics, Hernhutters, Jews	1,155,000	2,887,000	12,000
Gr. D. of Baden	5,970	1,130,000	Catholics, Lutherans, Calvinists, Jews	839,000	1,609,000	10,000
Gr. Duke of Hessen	3,760	700,000	Luther. Cath. Calv. Jews, Mennonites	648,000	1,114,000	6,195
Electoral Hessen	4,450	592,000	Evangelists, Catholics, Jews	639,000	272,000	5,679
Gr. D. of Saxe-Weimar	1,420	222,000	Lutherans, Catholics, Calvinists, Jews	203,000	672,000	2,100
Gr. D. of Mecklenb. Schwerin	4,770	431,000	Lutherans, Jews, Catholics, Calvinists	247,000	1,010,000	3,580
Gr. D. of Mecklenb. Strelitz	770	77,000	Lutherans, Jews	54,000	124,000	717
Gr. D. of Holstein-Oldenburg	2,500	241,000	Lutherans, Catholics, Calvinists, Jews	160,000	......	1,650
D. of Nassau	1,925	337,000	Evangelists, Catholics, Jews, &c	247,000	446,000	3,028

EURYALE, in *Mythology*, one of the Gorgons, daughters of Phorcys, and a sister of Medusa, who was subject neither to old age nor to death.

EURYDICE, in fabulous history, the wife of Orpheus, who flying from the attempted ravishment of Aristæus, was slain by a serpent. Her husband went down to the shades, and by the force of his music persuaded Pluto and Proserpine to allow him to carry back his wife to earth, a favour which they granted, provided he did not look on her till he reached the light; but in a moment of affection and forgetfulness he broke the condition, and Eurydice vanished from his sight.

EURYMEDON, in *Ancient Geography*, a noble river running through the middle of Pamphylia, and celebrated for a sea and land fight which took place on the same day, and in which the Athenians, under Cimon the son of Miltiades, defeated the Persians.

EURYSTHEUS, a king of Argos and Mycenæ, son of Sthenelus, and Nicippe the daughter of Pelops. Juno hastened his birth by two months, that he might come into the world before Hercules the son of Alcmena, as the younger of the two was doomed by order of Jupiter to be subservient to the will of the other. This natural right was cruelly exercised by Eurystheus, who was jealous of the fame of Hercules; and who, in order to destroy so powerful a relation, imposed upon him the most dangerous and uncommon enterprises, well known by the name of the labours of Hercules. The success of Hercules in achieving these perilous labours having greatly alarmed Eurystheus, he furnished himself with a brazen vessel, in which he might secure himself a safe retreat in case of danger. After the death of Hercules, Eurystheus renewed his cruelties against the children of the hero, and made war against Ceyx, king of Trachinia, because he had given them support, and treated them with hospitality. But he was killed in the prosecution of this war by Hyllus, the son of Hercules, and his head was sent to Alcmena, the mother of Hercules, who, mindful of the cruelties which her son had suffered, insulted it, and tore out the eyes with inveterate fury. Eurystheus was succeeded on the throne of Argos by Atreus his nephew. The death of Eurystheus happened about thirty years before the Trojan war.

EUSEBIANS, a denomination given to the sect of Arians, on account of the favour and countenance which Eusebius, bishop of Cæsarea, showed for them at their first rise.

EUSEBIUS, surnamed PAMPHILUS, a celebrated bishop of Cæsarea, in Palestine, and one of the most illustrious men of the Christian church, was born in Palestine, towards the close of the reign of Gallienus, about the year 267 of our era. He was the intimate friend of Pamphilus, who suffered martyrdom under Diocletian in 309, and, after his death, took his name in honour of his memory. He was ordained bishop of Cæsarea in 313. He had a considerable share in the contest relating to Arius, whose cause he, as well as several other bishops of Palestine, defended, being persuaded that Arius had been unjustly persecuted by Alexander, bishop of Alexandria. He assisted at the council of Nice in 325, when he made a speech to the emperor Constantine on his coming to the council, and was placed next to him on his right hand. In 330 he was present at the council of Antioch, in which Eustathius, bishop of that city, was unjustly deposed; but though he was chosen by the bishop and people of Antioch to succeed that prelate, he absolutely refused. In 334 he assisted at the councils of Cæsarea and of Tyre, by which Athanasius was condemned; and he was present at the assembly of bishops at Jerusalem during the dedication of the church in that city. By these bishops he was sent to the emperor Constantine to defend what they had done against Athanasius; when he pronounced the panegyric composed on that emperor during the public rejoicings in the beginning of the thirtieth year of his reign. Eusebius survived the emperor but a short time, and died in 338. Ecclesiastical writers, ancient and modern, are much divided in opinion respecting Eusebius. Several have defended him with warmth, in which number are Sozomenes, Socrates, Victorius, and some others. St Jerome, on the other hand, calls him the prince of Arians, Photius accuses him, the seventh council condemns him, and this opinion is generally followed by the moderns. The successor of Eusebius was Acacius, surnamed the One-eyed, a man not less learned or less eloquent, and more enterprising, than his master. Eusebius composed in Greek a multitude of works filled with eloquence and erudition; and those which have reached us, whilst they justify the high reputation of the author, cannot fail to occasion regret that so many have perished. He wrote, 1. the *Apology* or Defence *of Origen*, in six books; 2. a *Treatise against Hierocles;* 3. Fifteen books of *Preparationes Evangelicæ*, and twenty *De Demonstratione Evangelica;* 4. A *Chronicle* from the beginning of the world till the twentieth year of Constantine; 5. An *Ecclesiastical History*, of which Valetius published a good edition in Greek and Latin; 6. A *Paschal Cycle;* 7. A work against Marcellus of Ancyra, who was condemned at the council of Constantinople in 335 and 336; 8. Four books of the *Life of Constantine;* 9. Five books on the *Incarnation;* 10. Ten books of Commentaries on Isaiah; 11. Thirty books against Porphyry; 12. a book of *Topics;* 13. A *Nomenclature of Peoples and Nations*, according to the books of the Hebrews; 14. A *Topography of Judæa and the Temple;* 15. Three books of the *Life of Pamphilus;* 16. *Opuscula* on the Martyrs; 17. *Commentaries on the Psalms*; 18. A *Letter to Caspianus*, and a *Concordance of the Four Evangelists.* It appears also that he wrote a *Commentary on the first Epistle to the Corinthians*, and a *Treatise on the Accomplishment of the Predictions of Jesus Christ.* The greater number of his works, however, is only known by the testimony of St Jerome, who makes frequent mention of them, cites fragments of them, and appears to have used them very freely in the composition of his own works. Of those which have come down to us, the most considerable is the *Ecclesiastical History*, which has been translated into Latin by Rufinus, by Musculus, and by Christopherson. The version of the last-mentioned translator, printed opposite the Greek text, appeared in 1612. This work of Eusebius is of the greatest utility in reference to the history of the Christian church during the first three centuries, and it has earned for its author the honourable title of Father of Ecclesiastical History. In his *Chronicle*, which contains the principal actions of great men, and the history of discovery in the arts, Eusebius is supposed to have availed himself of the Chronology composed a century before by Julius Africanus. St Jerome translated the Chronicle into Latin, and continued it till the sixth consulate of Valens and Valentinian. The four books of the Life of Constantine have been printed with the Ecclesiastical History, and translated into French by Cousin. The ten books which remain of the *Preparatio Evangelica* and the *Demonstratio* were published at Paris in 1627, with the versions of Donatus and Vigerus, to which was subjoined the Treatise against Hierocles. It is in the *Demonstratio* that the invaluable fragment on Sanctification is contained. The Topography of the Holy Land, which St Jerome translated into Latin, was published in Greek by Bonfrère in 1631: it is also found in several editions of the works of St Jerome. The Commentary on the Psalms was published by Montfaucon; the *Opuscula* in Latin by Sirmond; the Letter to Caspianus and the Canons for a Concordance of the Gospels in the edition of the Greek New Testament, by Robert Estienne, 1550; the Notes on the Canticles by Meursius; and the fragments on the Lives of the Prophets by Curlerius, in his *Commentaries of Procopius on Isaiah.*

EUSTATHIANS, a name given to the Catholics of Antioch in the fourth century, on occasion of their refusal to acknowledge any other bishop except Eustathius, who had been deposed by the Arians. This denomination was given them during the episcopate of Paulinus, whom the Arians substituted instead of Eustathius, about the year 330, when they began to hold their assemblies apart. About the year 350, Leontius of Phrygia, surnamed the Eunuch, who was an Arian, and was put in the see of Antioch, desired the Eustathians to perform their service in his church; which offer they accepted, and the church of Antioch served indifferently both Arians and Catholics. This, we are told, gave occasion to two institutions, which have ever since subsisted in the church; the first, psalmody in two choirs; and the second, the doxology.

This conduct, which seemed to imply a kind of communion with the Arians, gave great offence to many of the Catholics, who began to hold separate meetings; and hence arose the schism of Antioch. Upon this, the rest, who continued to meet in the church, ceased to be called Eustathians, and that appellation was restricted to the dissenting party. Flavianus, bishop of Antioch, in 381, and one of his successors, Alexander, in 481, brought about a coalition or reunion between the Eustathians and the body of the church of Antioch, which is described with much solemnity by Theodoret (*Eccl.* lib. iii. c. 2.)

EUSTATHIANS were also a sect of heretics in the fourth century, who derived their name from their founder Eustathius, a monk, who was so foolishly fond of his own profession, that he condemned all other conditions of life. But whether this Eustathius was the same with the bishop of Sebastia and the chief of the Semi-Arians, is not easy to determine.

Eustathius excluded married people from salvation, prohibited his followers from praying in their houses, and obliged them to quit all they had, as incompatible with the hopes of heaven. He drew them out of the other assemblies of Christians, to hold secret meetings with him, and made them wear a particular habit; he ordained them to fast on Sundays; and he taught them, that the ordinary fasts of the church were needless, after they had attained to a certain degree of purity which he pretended to. He evinced great horror of chapels built in honour of martyrs, and of the assemblies held therein. Several women, seduced by his reasoning, forsook their husbands, and abundance of slaves deserted their masters' houses. He was condemned at the council of Gangra in Paphlagonia, which was held between the years 326 and 341.

EUSTATHIUS, archbishop of Thessalonica, and commentator on Homer, flourished at Constantinople in the twelfth century. Before his promotion to the see of Thessalonica, he was master of requests and master of orators, two ecclesiastical offices, the latter of which (namely, that of the orators or *rhetores*) had for its object to expound the sacred writings to the people. It was during this first part of his public career that he wrote his commentaries on Homer and on Dionysius Periegetes. His remarks on Dionysius have been frequently printed along with the text of that author, and Politi has given a Latin translation of them, Geneva, 1741, in 8vo. But these, however useful and deserving of commendation, are in no degree comparable to the *Commentaries* on the Iliad and Odyssey, which embody an immense treasure of literary and grammatical erudition, chiefly extracted and compiled from preceding scholiasts and commentators, as Apion, Herodorus, Demosthenes of Thrace, Porphyry, and some others, the additions made to their observations by Eustathius himself being neither very considerable nor very important. To these *Commentaries*, as well as to his *Annotations* on Dionysius, the learned commentator has given the modest title of *Parecbolæ* or Extracts; desirous, no doubt, that those who might neglect to read his preface should learn from the title alone the nature of his work, and thus be prevented from attributing a disproportionate share of merit to the compiler. The commentaries of Eustathius on the Iliad were printed for the first time at Rome, 1542–1550, in four vols. folio, including the beautiful table of Devaris. But as this edition is exceedingly scarce and high-priced, that of Bâle, printed by Froben, 1559–1560, in three vols. folio, which is the next in point of authority, may be advantageously consulted by scholars, in default of the former. It must not be confounded, however, with an *Abridgment* of Eustathius, of which Hadrian de Jonghes was editor, and which appeared at Bâle, from the press of the same Froben, 1558, in one volume. Claude Capperonier, who had promised a new Greek and Latin edition of the *Commentaries* of Eustathius, died without having published any part of it; but Politi, whom we have already named, undertook this great work, of which he published at Florence, 1730–1735, three vols. folio, containing the first five books of the Iliad. It is to be regretted, however, that Politi took the trouble to translate into Latin a work which is only suitable to those who are deeply versed in the Greek language, and for whom the aid of a translation is superfluous; and it was probably this useless addition which caused the interruption of the enterprize. With reference to the extracts from the Commentaries of Eustathius which Müller and Clarke have given in their respective editions of the Iliad, it is only necessary to mention here, that these have, in each case, been made upon a principle of selection adapted to the peculiar nature and object of the undertaking. It is of more importance to observe, that at the period when Eustathius lived original literature had almost disappeared, and that consequently this vast and important compilation secured to him an immense reputation. Intended at first for the bishopric of Myra in Lycia, he was soon afterwards appointed archbishop of Thessalonica, and in the exercise of his high functions displayed a dignified and respectable character. The year of his death is unknown; but he was alive in 1194, and it may be conjectured that he died after 1198, at a very advanced age. Eustathius appears, from his Notes on the *Canons* of Joannes Damascenus, to have composed several works besides those which we have already mentioned; particularly a Commentary on Pindar, which is almost entirely lost; Homilies, Discourses, Remarks on the Canons of St John of Damascus, and Letters which are preserved in different libraries. Manutius has also inserted in the *Gardens of Adonis* a little treatise of Eustathius on the dialects of Homer, but this tract is merely an insignificant extract from the grammatical observations contained in that Life of Homer which some attribute to Plutarch, and others to Dionysius of Halicarnassus.

EUSTATIA, ST, one of the Leeward Islands, in the West Indies. It is a high rock, rising from the waves in the form of a pyramid, gradually tapering to the top. It is twenty-nine miles in circumference at the base, and, notwithstanding the singular conformation of the island, the climate is healthy, and the soil, which is cultivated to the very summit, most prolific. It is, however, like other islands in this region of the globe, subject to the desolating visitation of thunder-storms and hurricanes. The latter are most to be dreaded during the months of August and September; and they have been frequently so severe as to lay waste the island and scatter the shipping. There is only one landing-place, and that, though difficult of access, is strongly fortified;

indeed the whole island has been rendered nearly impregnable when properly garrisoned. Sugar, cotton, and maize are here produced; but the vegetable production most cultivated is tobacco. Small as this island is, it is said to support nearly twenty thousand inhabitants, who, besides their agricultural avocations, rear hogs, kids, rabbits, and all kinds of poultry, with which they are enabled to serve their neighbours after having supplied themselves. This island was settled by the Dutch as early as the beginning of the seventeenth century; but in 1665 it was taken by the British, who in their turn were ejected by the French. In 1781 it yielded to Admiral Rodney; from the English it was again wrested by the French, and after repeatedly changing masters according to the varying fortunes of war, it was finally transferred to the Dutch government at the peace of 1814. St Eustatia lies fifteen miles south of Saba, and eight miles north-west of St Christophers. Long. 63. 5. W. Lat. 17. 31. N.

EUSTYLE, in *Architecture*, a sort of building in which the pillars are placed at the most convenient distance from one another, the intercolumniations being two diameters and a quarter of the column, excepting those in the middle of the face, before and behind, which are three diameters apart.

EUTERPE, one of the Muses, daughter of Jupiter and Mnemosyne, who presided over music, and was also regarded as the inventress of the flute. She is represented as crowned with flowers, and holding a flute in her hands. Some mythologists attribute to her the invention of tragedy, which is more commonly supposed to be the production of Melpomene.

EUTHYMIA, among the Greeks, signified such a disposition or state of the mind as could not be ruffled either by good or bad fortune, by health or sickness, pleasure or pain, good or evil.

EUTIN, a city in that part of the duchy of Oldenburg which lies on the Baltic Sea, called the duchy of Lubec. It is situated on a beautiful lake, and is surrounded by the Danish province of Holstein. It contains, besides the ducal palace, 260 houses and 2540 inhabitants. Long. 10. 51. E. Lat. 54. 8. N.

EUTROPIUS, FLAVIUS, a Latin historian, of whose life we know but little. Even the prænomen Flavius is uncertain, as well as the race from which he sprung. Some consider him as a native of Italy, others of Gaul, and others again of Constantinople, without our possessing any certain grounds to enable us to decide on the one more than the other. We know that he lived under Constantine Epistolaris, afterwards accompanied Julian against the Persians, and also lived under Valens. But it is uncertain whether the Eutropius named as proconsul of Asia, and another who was præfectus prætoris 381 A. D. be the same person as the historian. His death took place probably in the wars of Valens, and before the death of Sapor, 370 A. D. Eutropius left an epitome of Roman history (*Breviarium Historiæ Romanæ*) in ten books, from the building of Rome to the reign of Valens. At the conclusion he promises a work on the same subject in a more extended form, in consequence of a wish expressed by the emperor, to whom it is dedicated; but we are unable to state whether he put his intentions into execution. The epitome has been generally extracted from sources worthy of credit, from some indeed to which we have no longer access. It carefully omits, however, all that may appear prejudicial to Rome: it follows generally a chronological order. The style is unadorned and simple; and we need not be surprised if he exhibits traces of the corruption of the age in which he lived, and that some of his expressions are less refined than what are found in classical writers. There were two translations of it into Greek, of which the one by Capito Lycius, in the time of Justinian, has perished; but the other, by a certain Pœericus, is still preserved. See Voss. *De Hist. Lat.* ii. 8; Fabric. *Biblioth. Lat.* iii. 9; Moller, *Dissert. de Eutrop.* Altorf, 1685; Tzschucke, *Diss. de Vita*, &c. in his edition of the work, Lips. 1796; Bähr, *Geschichte der Romischen Literatur*, Carlsruhe, 1832.

EUTYCHIANS, ancient heretics, who denied the double nature in Christ, and were so denominated from Eutyches, the archimandrite, or abbot of a monastery at Constantinople, who began to propagate his opinion in the year 448. This man, however, did not seem quite steady and consistent in his sentiments, for he appeared to allow of two natures, even before the union; a consequence he apparently drew from the principles of the Platonic philosophy, which supposes a pre-existence of souls. Accordingly, he believed that the soul of Jesus Christ had been united to the divinity before the incarnation; but then he allowed no distinction of natures in Jesus Christ after his incarnation. This heresy was first condemned in a synod held at Constantinople by Flavian, in 448, the proceedings of which were approved by the council of Ephesus, called *conventus latronum*, in 449, and re-examined and condemned in the general council of Chalcedon in 451. The legates of Pope Leo, who assisted at the latter, maintained that it was not enough to define that there were two natures in Jesus Christ; but insisted strenuously, that, in order to remove all equivocations, they must add these terms, "without being changed, or confounded, or divided."

The heresy of the Eutychians, which made great progress throughout the East, at length became divided into several branches. Nicephorus makes mention of no fewer than twelve; some called *Schematici*, or *Apparentes*, as only attributing to Jesus Christ a phantom or appearance of flesh; others, *Theodosians*, from Theodosius, bishop of Alexandria; others, again, *Jacobites*, from one *Jacobus* of Syria, which last branch established itself principally in Armenia, where it still subsists. Others were named *Acephali*, headless, and *Severians*, from a monk called Severus, who seized on the see of Antioch in 513. These last were split into five subdivisions, namely, *Agnoetæ*, who attributed some ignorance to Jesus Christ; the followers of Paul; Μελαινοι, or the black *Angelites*, so called from the place where they were assembled; and lastly, *Adrites* and *Cononites*.

EUTYCHIANS was also the name of another sect, half Arian half Eunomian, which arose at Constantinople in the fourth century.

It being then a matter of great controversy amongst the Eunomians at Constantinople, whether or not the Son of God knew the last day and hour of the world, particularly with regard to a passage in the gospel of St Matthew (chap. xxiv. ver. 36), or rather to one in St Mark (xiii. 32), where it is expressed that the Son did not know it, but the Father only; Eutychius made no scruple to maintain, even in writing, that the Son did not know it: and this opinion having displeased the leaders of the Eunomian party, he separated from them, and made a journey to Eunomius, then in exile, who fully acquiesced in Eutychius's doctrine, and admitted the latter to his communion. But Eunomius having died soon afterwards, the chief of the Eunomians at Constantinople refused to admit Eutychius; who, upon this, formed a sect of such as adhered to him, who were called *Eutychians*.

This Eutychius, with one Theophronius, were the occasion of all the changes made by the Eunomians in the administration of baptism; which, according to Nicephorus, consisted in only using one immersion, performed not in name of the Trinity, but in memory of the death of Jesus Christ. Nicephorus calls the chief of that sect, not *Eutychius*, but *Eupsychius*, and his followers *Eunomiaupsychians*.

EUTYCHIUS, patriarch of Alexandria, lived about the ninth century; and wrote annals in the Arabic language, printed at Oxford in 1658, with a Latin version by Pococke. Selden had printed something of his before.

EUXINUS PONTUS, Black Sea, lying between Europe and Asia, into which several of the largest rivers in the world flow; on the west the Danube, Dniester, and Dnieper, on the east the Phasis, and on the south the Helys and Thermodon. A large peninsula stretches into the centre, and divides it into two great gulfs; the cape in the Crimea was called Criu-metopon (*Karadje-Bouroun*,), and that in Asia, Carambis (*Kerempi-Bouroun*), being distant from each other 170 miles. According to Strabo, its circumference was 25,000 stadia, equal to 715 leagues, which is very nearly correct. The ancients believed that at one time it had no communication with the Mediterranean, but that the rivers which flow into this sea having opened for themselves a passage, the waters rushed into the Mediterranean by the Hellespont, and caused that sea to burst a passage through the Straits of Gibraltar. (Strab. i. 49.) In the time of Diodorus the inhabitants of the island Samothrace preserved the recollection of an inundation which had elevated the waters of the Mediterranean to such a height that their ancestors were obliged to take refuge on the summits of their highest mountains; and so late as the first century of the Christian era they had the custom of sacrificing on altars placed on the spot to which they believed the waters to have risen. There seems every reason to believe that the Black Sea, Caspian, and Aral, were once united, and perhaps found a vent to the North Sea by the valley through which the river Oby flows from Tobolsk. This immense lake was bounded to the north by the lofty mountains of Asia Minor and Armenia; and when by their weight the waters burst the barrier opposed to them on the side of the Bosphorus, it may easily be conceived with what a fearful shock they must have poured into the Mediterranean. See *Storia Filosofica della Navigazione, del Commercio e delle Colonie degli antichi del Mare Nero*, by Formaleoni, Venet. 1788; also Notes on French Strabo, Paris, 1805.

EVAGRIUS SCHOLASTICUS, an historian, born at Epiphania about the year 536. He practised the profession of advocate, from which he was called *Scholasticus*, a name which was then given to the pleaders at the bar; and he was also tribune and keeper of the prefect's dispatches. He wrote an ecclesiastical history, which begins where those of Socrates and Theodoret ended; besides other works, for which he was rewarded by the emperors Tiberius and Mauricius. M. de Valois published at Paris a good edition of Evagrius's ecclesiastical history in folio; and it was republished at Cambridge in 1620, in folio, by William Reading, with additional notes of various authors.

EVANDER, a king of Arcadia, said to be son, sometimes of Mercury and sometimes of Echemus, king of Arcadia, had as his mother the nymph Nicostrate or Carmenta, according to the Latins. Various reasons are given to account for his emigration to Italy. According to Servius (Virg. *Æn.* viii. 51, 130), he had killed his father by accident; but Ovid says that he was compelled by civil broils to abandon his kingdom to his brother Ladocos. This event is supposed to have taken place about fifty years before the taking of Troy. Faunus, who then reigned in Italy, received Evander and his companions with great kindness, granting to him as much land as was necessary to build a city. Its foundations were laid on the Palatine hill; and it was called Pallatium or Pallanteum, either in honour of his son Pallas, or in remembrance of a village of the same name in Arcadia. Evander was greatly annoyed by the thefts of a giant named Cacus, who dwelt on the Aventine hill; but Hercules, whom he received with much hospitality, freed him from this formidable enemy. At a later period Virgil introduces him to us, as forming an alliance with Æneas, and furnishing him with a body of troops commanded by his son Pallas. (*Æn.* viii. 154). He gave laws to his people, taught the aborigines of Italy agriculture, invented music, and introduced into his new country the knowledge of letters. After his death he was by the gratitude of his subjects ranked among the gods.

EVANGELISTS, the inspired authors of the Gospels. The word is derived from the Greek ευαγγελιον, formed of ευ, *bene*, *well*, and αγγελος, *angel* or *messenger*.

The denomination of *evangelists* was likewise given in the ancient church to those who preached the gospel in different parts, without being attached to any particular church, being either commissioned by the apostles to instruct the nations, or having of their own accord abandoned every worldly attachment, and consecrated themselves to the sacred office of preaching the gospel. In this sense it is, according to some interpreters, that St Philip, who was one of the seven deacons, is called the *evangelist* in the twenty-first chapter of the Acts of the Apostles. Again, St Paul, writing to Timothy (Ep. ii. chap. iv. ver. 5), bids him do the work of an evangelist; whilst the same apostle (Eph. iv. 11) ranks the evangelists after the apostles and prophets.

EVANTES, in *Antiquity*, the priestesses of Bacchus, who were so called because in celebrating the orgia they ran about as if distracted, crying, *Evan, evan, ohe evan.*

EVAPORATION is that process by which liquids and solids gradually assume the gaseous form, or by which, in certain circumstances, an invisible vapour or gas is continually detached from the surface of water, and perhaps of every other liquid, as also from the surfaces of many, if not every solid. From this process being generally found to lower the temperature of the evaporating body, an effect which might have been expected from the doctrine of latent heat, it is probable that heat enters largely into the constitution of every vapour, and is therefore supposed to be the principal agent. At a given temperature, a cubic foot or other determinate space, incumbent over a liquid, cannot contain above a certain quantity of the same kind of vapour; and when it contains that maximum, it is said to be saturated. If, therefore, after this is the case, any additional vapour continue to be thrown off, it must either fall back immediately into the liquid, or, if slightly cooled, may apparently remain suspended in the visible form of a cloud, which, however, is not properly vapour, but minute drops, formed by the cooling of it, and which successively fall back into the liquid. For evaporation continues to go on under the pressure of air or other gas, however dense, but ceases in the presence of any gas, however rare, if already saturated with the same vapour, unless such gas be colder than the evaporating body; in which case, however, the vapour being partly condensed into drops, becomes cloudy, as was just mentioned; and sometimes liquids, while in the act of ebullition, which is rather an extreme case of evaporation, throw up small drops, which may be seen alternately rising and falling in the vapour. Such is a summary of a few of the leading facts, several of which we shall have occasion to touch on more fully, along with other particulars, whilst briefly noticing, as we shall now do, some steps in the history of this inquiry, before proceeding farther.

The spontaneous disappearance of water, and the drying of humid bodies, or the tendency which moisture has to escape from them and diffuse itself in the atmosphere, and afterwards to descend as rain, snow, dew, &c. must have been familiar to mankind in every age, condition, or climate; but any thing like an approach to a rational explanation of the facts seems to be of very modern date. Some of the ancients, particularly Aristotle, conjectured that fire was concerned in the process; but such of their notions as have come down to us are so little to the purpose, that they need not now be dwelt upon. Halley supposed that aqueous vapour consisted of small hollow spherules, filled with something so very light, that they readily ascended and floated in the air,—a theory not altogether such as might have been expected from the known sagacity of its author; for, though Descartes seems to have hinted at the same thing long before, it scarcely appears to have had the least shade of truth in it. But so completely was Kratzenstein's imagination filled with this doctrine, that he fancied he could see these vesicles with a microscope, and even discern them to be hollow, notwithstanding their being supposed to form a transparent vapour. If he really saw any thing, it was more probably minute drops of water descending in the air. Nay, almost up to the close of the last century, we find many eminent men, and among these the late able mathematician Mr George Atwood, maintaining and speculating on this vesicular theory, as it was called. Halley, it is true, hinted at another theory, which not a few embraced, and for which some have still a predilection, namely, that air holds moisture united to it by chemical solution or affinity; but the first idea of this seems to be due to Hooke. A different explanation was attempted by Desaguliers, who, after pointing out the defects of former theories, showed that water is capable of being converted into a transparent elastic fluid, which he supposed to be many times lighter than air, and that it could therefore ascend and float in the atmosphere; but he some time afterwards inclined to ascribe the ascent of vapour to an electrical attraction of the air. Desaguliers was no doubt greatly mistaken regarding the specific gravity of steam, which, under the same pressure and temperature, is now known only to fall short of that of air in the ratio of five to eight; but he was perhaps the first who thought of identifying pure steam with the attenuated aqueous vapour diffused in the atmosphere. It would seem that prior to Desaguliers advancing this notion, it was not known that steam is always generated in a transparent state, although minute drops of water may be passing or falling through it; and indeed some are scarcely aware of this at the present day. The fact is, that steam or aqueous vapour preserves its transparency so long as it has neither lost heat nor had its volume enlarged; but so soon as its temperature is lowered, whether from losing heat or from enlargement of volume, it is more or less condensed into minute drops of water, which of course render it opaque. For we can on no account admit the very generally received doctrine of M. Clement, that equal weights of steam, if in contact with water, contain equal quantities of heat, whatever be their volumes or temperatures. On the contrary, we cannot help believing that a given weight of steam requires more heat to maintain it in the transparent elastic form, when under a greater volume, than under a less; and in proof of this, we presume it is only necessary to adduce the following fact. If we open a stop-cock in the cover of a boiler when the pressure is only one atmosphere, the steam which issues preserves its transparency till it get to some distance from the orifice; but when the pressure within amounts to two or three atmospheres, the steam, if allowed to issue freely, is opaque from the very orifice. This clearly shows that the same quantity of heat (we do not mean temperature) which had been amply sufficient to maintain the steam in the transparent form under a smaller volume within the boiler, is quite inadequate to do so when the steam is allowed to enlarge its volume under a reduced pressure. A more palpable or satisfactory proof than this, which has been long before the public, is scarcely to be wished; yet we find Dr Lardner not long ago reading a paper to the Royal Society on the heat of steam, and which has for its foundation the untenable theory of Clement. Indeed M. Clement's mode of experimenting was so fallacious, that it would have given him the same results whether his theory had been true or not. For when the stream of steam is very small, and of course passes through the stop-cock with difficulty, as it must have done in his experiments, it has, while in the act of dilating from under a force of two or three to that of one atmosphere, the opportunity of absorbing heat from the metal of the scarcely open stop-cock, then much hotter than 212°, the temperature to which the dilating is supposed to reduce the steam. No wonder then that equal weights of steam, at first so different in density, should, when received in equal quantities of cold water, produce equal rises of temperature; as is pointed out more particularly in the *Philosophical Magazine* for July 1826, p. 38. It is likewise to be remembered, that though in the other experiment the steam must have been absorbing some little heat from the stop-cock, this did not enable it to preserve the transparent form. We have been the more particular in clearing up this point, because we shall shortly have occasion to refer to it.

Researches of Saussure.

From the time of Halley and Desaguliers to about 1770, a variety of essays on evaporation made their appearance, which, however, tended but little towards elucidating the subject, because they were either not founded on experiments at all, or on such as were not sufficiently elementary. Some of these sought to establish the vesicular system, while others advocated that of chemical solution and electrical attraction. At length, in 1783, came forth the well known *Essais sur l'Hygrométrie* of M. de Saussure, who, though he did not labour so much to establish new theories as to blend together or combine some of those already mentioned, certainly added considerably to the stock of facts. But he at the same time greatly indulged his fancy in supposing aqueous vapour to be capable of existing in four different forms. When it alone occupied a space, he called it *pure elastic vapour*; when diffused in a transparent state in the air, he named it *dissolved elastic vapour*, imagining it to be chemically dissolved by the air; but after the air was quite saturated with this sort, he thought some of it assumed the form of *vesicular vapour*, only differing from that of Halley in being visible. To these he added *concrete vapour*, which consisted of liquid drops, such as form clouds and fogs; a real form of moisture to be sure, but one which is not properly vapour at all. In these *Essais* we have an account of a variety of experiments, most of them having the advantage of being executed on a great scale; but, on the other hand, they were often deficient in that elementary simplicity which is so important in a research of this nature, if we would avoid sources of fallacy. By inclosing a known weight of caustic alkali in a very large glass balloon, previously filled with thoroughly damp air, Saussure endeavoured to find what quantity of moisture this air contained, from the increase of weight which it communicated to the alkali; and conversely, by weighing a bit of wet linen, and suspending it in the balloon filled with dry air, he estimated how much moisture had evaporated from the linen to render the air thoroughly damp. These two methods not only gave him nearly the same result, but did so whether he used air hydrogen or carbonic acid in the balloon, and even when he employed a mixture of these gases. During these experiments he also observed, by means of a gauge, what change of pressure took place within the balloon from the change of humidity.

By operating at different temperatures, he obtained results from which different conclusions might be drawn to suit different theories; for instance, that the quantity of vapour which could exist in the balloon varied in geometrical progression for equal intervals of temperature, and nearly as the square root of the air's density; and that air of the ordinary density could contain five times as much vapour as a vacuum did; all of which conclusions are now known to be incorrect. Prior to this, Lambert had, from his experiments, drawn a very different but still more erroneous conclusion, that the quantity of moisture varied as the *square* of the air's density.

Theory of Deluc and Dalton.

It was natural to think that the great discordance between the results of these celebrated philosophers should have raised doubts whether they might not both have deceived themselves by too complex a mode of operating, and, therefore, that neither of them was likely to be correct. Accordingly we find M. Deluc, in his *Idées sur la Metéorologie*, hinting at an incomparably more simple theory, which he afterwards developed more fully in the *Philosophical Transactions* for 1792, viz. that the quantity of vapour which can exist in a given space depends upon the temperature alone, and is independent of the presence or density of air, or of any other elastic fluid with which the vapour forms no chemical combination, being the same as if nothing but the vapour occupied that space. In this speculation he also maintained, as Desaguliers had done, that pure steam and the attenuated aqueous vapour diffused in the air are the same. Something similar to this theory was advanced by M. Pictet in his *Essai sur le Feu*, and still more so by Dr Dalton in his *Meteorological Essays*; and it is not improbable that each might have hit upon the same theory before knowing what the others had done. By inclosing his hygrometer along with a little water under a receiver, Deluc found that the indications of that instrument were the same whatever was the density of the included air, or however much he exhausted it; and the same thing held true with other gases. Volta, likewise, from a great variety of experiments, was led to acquiesce in the theory of Deluc.

Dr Dalton's researches.

The theory was farther investigated, in a much more elementary way, by Dr Dalton, as detailed in the *Manchester Memoirs*, vol. v.; but preparatory to noticing it, we shall subjoin his manner of expressing himself on the subject in his *Essays*, p. 201, where, from certain experiments and observations, he infers "that the vapour of water, and probably of most other liquids, exists at all temperatures in the atmosphere, and is capable of bearing any known degree of cold without a total condensation, and that the vapour so existing is one and the same thing as *steam* or vapour of 212° or upwards. The idea, therefore, that vapour cannot exist in the open atmosphere at a lower temperature than 212°, unless chemically combined therewith, I consider as erroneous; it has taken its rise from a supposition that *air* pressing upon vapour condenses the vapour equally with *vapour* pressing upon vapour; a supposition we have no right to assume, and which, I apprehend, will plainly appear to be contradictory to reason and unwarranted by facts; for when a particle of vapour exists between two particles of air, let their equal and opposite pressures upon it be what they may, they cannot bring it nearer to another particle of vapour, without which no condensation can take place, all other circumstances being the same; and it has never been proved that the vapour in a receiver from which the air has been exhausted is precipitated upon the admission of perfectly dry air. Hence, then, we conclude, till the contrary can be proved, that the condensation of vapour exposed to the common air does not in any manner depend upon the pressure of the air." The method which Dr Dalton took to clear up this question is distinguished by an elegant simplicity. In the *first* place, he determined by experiment the expansive force of dry air for each degree of temperature between 32° and 212°; and was the first who did so with any thing like accuracy. He at same time found that 1000 cubic inches of air at 32° expanded to 1376 on being heated to 212°, which comes surprisingly near 1375, the result published by M. Gay Lussac shortly after. But through some inadvertency Dr Lardner (on Heat, p. 57) makes Dr Dalton's result 1325, and then gravely adds, that "the latter (Gay Lussac's) determination has been proved by subsequent experiments to be the more correct." *Secondly*, Dr Dalton ascertained the force of pure steam in contact with water for each degree throughout the same range; and, *thirdly*, he found at what rate dry air expanded, when put in contact with water, and then heated through the various degrees of that range. The result was, that at any particular temperature, the expansive force of dry air in the first case, added to the force of vapour in the second, was exactly equal to their joint expansive force in the third. From this it is obvious that there is either no chemical combination between the air and vapour, or that such combination, if it exist, is quite inert, or goes for nothing so far as this research is concerned. Dr Dalton found, that when other gases were substituted for air, the vapour gave the same results; and similar results were obtained when other vapours were treated as steam. M. Desormes, likewise, by operating in a manner very different from that of Dr Dalton, found the quantity of vapour to be independent of the presence of air or other gases. The question was also examined experimentally by M. Gay Lussac, with his well-known accuracy and ability, and his results precisely agreed with those of Dr Dalton. Still more recently Professor Daniell has made a great variety of interesting experiments on mixtures of gases and vapours, in a manner similar to that employed by Deluc, but with the help of an incomparably better hygrometer; and his researches, too, corroborate the theory completely.

Several objections have been made to this theory; but all of them with which we are acquainted are so nugatory and irrelevant that we do not think they require any refutation. There is, however, a point which the foes as well as the friends of the theory have taken for granted, and which, though extremely probable, it would, for any thing we can see, be very difficult to prove in a direct and unexceptionable manner; viz. that the expenditure of heat in forming a given weight of vapour is the same, whether the process take place in air or other gas, or in a vacuum. Since in most combinations heat is given out, it is a wonder that those who contend for the solution of vapours in gases have not founded some objection on this; for we presume it is the only point on which a doubt could be palmed respecting the theory. It is generally taken for granted too, that the expenditure of heat in forming a given weight of vapour is the same at every temperature; but this assumption we cannot help regarding as very erroneous, because to us it appears quite clear that the expense of heat is greater when the vapour is rarer; and this we maintain for the following reason. The density of steam at 212°, for instance, is about 109 times greater than at 32° Fahrenheit; and we have already seen that steam loses in a considerable degree the elastic form by being dilated to two or three times its bulk; how much more then if dilated 109 times? Hence steam rarefied to such a degree would need a large addition of heat to enable it to maintain the gaseous form; in other words, much more heat must be expended or become latent in forming a given weight of vapour at 32° than at 212°. If steam, when kept separate from water, have its temperature raised by compression at the same rate as air has, it might be shown that the expense of heat in forming vapour at 32° would be to that at 212° as thirteen to eight nearly, that is, in the ratio of the logarithms of the number of times the steam is rarer than water. See *Philosophical Magazine* for April 1832, page 246.

Vapours and gases agree in so many of their properties, that there seems no doubt of their being but one and the same form of matter. Thus, so far as has been examined, every vapour, when kept separate from any sensibly evaporating liquid, expands by heat at the same rate as air and other gases do; and, like gases too, it observes the law of Boyle, by having the force at a given temperature proportional to the density. But since the density of a vapour in contact with its generating liquid increases with the temperature, its force, when so situated, increases much more rapidly than that of air or a mere gas does. However, the precise law which connects the temperature with the density or force seems to be as yet unknown. Dr Dalton having, as already mentioned, ascertained by experiment the force of aqueous vapour between the temperatures of 32° and 212°, deduced from the results what he considered to be the relation between the force and temperature, and for some time it was supposed that by means of it the force could be had for temperatures beyond both limits of that range. Accordingly on this principle he constructed a table which extended from —40°F. up to 325°; and indeed he was pretty fortunate in the extension below 32°, because the half of it has since been so nearly confirmed by the very accurate experiments of M. Gay Lussac, which were carried down almost to —20° *cent.* or —4°F.; but above 212° the supposed law was soon found to give the force too small, and the more so as the temperature is higher. Yet Dr Lardner, in his recent treatise on heat, gives this part of the table expressly as the result of Dalton's "accurate experiments," and not as it really was, a mere extension by means of a formula; nor does he warn us of its erring almost two atmospheres at the upper extremity. It is likewise curious that Dr Lardner, while he notices performances of far less merit, is totally silent respecting the labours of the Committee of the Royal Academy of Sciences at Paris in 1829; though they executed by far the most extensive and accurate experiments that ever were made on steam at high temperatures, as will be found detailed in the *Annales de Chimie* for January 1830. All the English abstracts from this which we have seen are very incorrect. Dr Dalton has more recently published another table of the force of vapour adapted to some of his theoretical views; but from its differing considerably from the results of others, especially those of Gay Lussac, we do not consider it so correct for low temperatures as his first one, part of which is given farther on in this article.

The method employed by M. Gay Lussac to determine experimentally the force of vapour at low temperatures is particularly commendable, and yet its merits seem to have been very much overlooked, even by those who were engaged in similar researches. It may therefore be useful to give a brief account of it here. Other philosophers had either not carried their experiments below 32° at all, or had mismanaged the matter by allowing water to freeze in the tube in such a manner as to obstruct the free motion of the mercury, and likewise to render its altitude ill defined and difficult to be seen. These inconveniences were dexterously avoided by Gay Lussac, who still employed a barometer tube, but one so much longer than ordinary that a considerable part of it next the sealed end was above the mercury, and a portion of this, being bent to about an angle of 60°, was immersed in a cold mixture along with a thermometer. The consequence of this arrangement was, that neither the mercury nor the small portion of water on its top necessarily required to be cooled down at all; because, however moderate their temperature might be, the force of every portion of the included vapour being in equilibrio with the force of that which touched the coldest part of the tube, was just the same as if the whole vapour had been at the temperature of the freezing mixture. A farther advantage was, that after the apparatus had been allowed to remain for a short time in the state now described, the water entirely disappeared from the top of the mercury, having been transferred by evaporation or distillation to the sealed end of the tube, where it was quickly frozen. By this means the mercury became almost as free from moisture as if none had been in the tube. It is, besides, evident that this method could be carried down, not only to and below the freezing point of mercury, but to any temperature, however low, to which the extremity of the tube could be cooled; and that it is applicable to every sort of vapour which does not act upon mercury. In fine, Gay Lussac having placed a barometer tube filled with dry mercury beside and in the same cistern with the one which contained both mercury and moisture, read off the difference in the heights of their mercurial columns with great precision, by means of a microscope which could be shifted up and down a graduated pillar, and the difference was obviously the force of the vapour. Although mercury evaporates at all temperatures, as appears from a bit of gold-leaf becoming white if long suspended over it in a phial, and from the noxious effects of breathing air which has been for some time in contact with a large surface of mercury, yet the force of its vapour is so very small compared with that of steam, that it could not sensibly affect these experiments. Indeed it seems to be a general law, that the forces of vapours from liquids which have high boiling points, are quite inappreciable at low temperatures.

Researches on the rate of evaporation.

The most important problem connected with the evaporation of water is to determine the rate at which, under certain circumstances, it escapes from a given surface at a particular temperature. Many cases of this problem are still very imperfectly solved. The experiments of Dr Halley, detailed in No. 189 of the *Philosophical Transactions*, seem to be among the earliest which were employed for this purpose. He found that water salted to the state of sea water, and exposed to a heat equal to that of a summer's day, did, from a circular surface of eight inches diameter, evaporate at the rate of six ounces in twenty-four hours. Hence he concludes, that a square degree of sixty-nine miles will evaporate 33,000,000 tuns in a day; and supposing the Mediterranean to contain 160 square degrees, it would evaporate 5,280,000,000 tuns daily. This quantity he considers sufficient to supply all the rains, springs, dews, rivers, &c. It would however be of little use to rehearse the whole of this speculation, because the data, as we shall afterwards see, were too loose, and the experiment was on too small a scale, for such a comparison. Dr Lardner, in touching on this subject in his treatise on heat, says, that in the Straits of Gibraltar, instead of an outward current, there is a rapid and never-ceasing inward flow of water, and that he is therefore compelled to conclude that the evaporation from the surface of this sea carries off the enormous quantity of water supplied from this and other sources. Such doctrine from so respectable a quarter rather surprises us; since it is quite well known that, besides the inward current, which is principally in the middle of the surface, there are generally outward currents, likewise at the surface, next the coasts, particularly the south one, and most probably also in the immense deep beneath. According to Professor Robison, the water sometimes flows outward, even in the middle of the surface. Had there been no outward current, the Mediterranean must long ago have become as salt as the brine of the Dead Sea; or rather perhaps have become a rock of salt, as Dr Thomas Young remarked; for, as we shall afterwards see, no common salt or other muriate rises from the sea by evaporation. In

Dr Halley's experiments.

Water carried in by the current at Gibraltar cannot be all spent by evaporation.

order that the same degree of saltness may continue, the outward currents must just bear away as much salt as the inward current and other sources supply, with the very slight exception of what the wind carries off in the form of spray, water spouts, &c. The waters of the Mediterranean being, as is well known, specifically heavier, especially at a great depth, than those of the Atlantic, will naturally incline to buoy them up, and flow out beneath them in the infathomable depth of the Straits.

Dr Dobson's experiments.

A series of experiments on the evaporation of water at natural temperatures was continued for four years, beginning with 1772, by Dr Dobson, at Liverpool, as detailed in the *Philosophical Transactions*, vol. lxvii. He took a cylindrical vessel twelve inches in diameter, and having nearly filled it with water, exposed it beside his rain-gauge of the same aperture; and by adding or withdrawing water, as occasion required, he kept the surface at nearly the same height. By comparing the total quantities thus added or taken away with the proceeds of the rain-gauge, the amount of evaporation was ascertained. The mean monthly evaporation for the four years was, in January, 1·5 inches; February, 1·77; March, 2·64; April, 3·3; May, 4·34; June, 4·41; July, 5·11; August, 5·01; September, 3·18; October, 2·51; November, 1·51; December, 1·49. In all, 36·78 inches. The mean rain for the same time was 37·48. For a great deal more in this way, and on the evaporation of ice and snow, see Howard's excellent treatise on *The Climate of London*. That ice and snow evaporate, appears from their losing weight, or even disappearing altogether, if long enough exposed to a brisk and dry wind during frost. But sometimes snow is rendered so much colder by radiation than the incumbent still air, that it condenses the vapour of that air into hoar-frost, and by that means augments its own weight or bulk.

But the experiments of Dr Dalton and Mr Hoyle, though rather of local application, were no doubt far more accurate for evaporation from the soil. Having got a cylindrical vessel three feet deep and ten inches in diameter, two pipes were joined to it, and turned downwards for the surplus rain-water to run off into bottles; the one pipe being near the bottom, the other an inch from the top. The vessel was filled up for a few inches with gravel and sand, and the remainder with good fresh soil. It was then put into a hole in the ground, and the space around filled up with earth, except on one side, for the convenience of afterwards joining bottles to the pipes, and registering their contents. The earth in the vessel was now saturated with moisture, by pouring in water till some of it escaped from the pipes; and, lastly, the bottles were put to. During the first year the soil was bare at top; but for the next two years it was covered with grass, like any green field. A regular register was kept of the rain-water which ran off through the upper pipe, and also of what sunk down through the earth to the lower pipe. A rain-gauge of the same diameter was kept close by, to register the quantity of rain for any corresponding time.

From these experiments it appears, 1*st*, That the mean annual quantity of water evaporated in the above circumstances is twenty-five inches of rain, to which if we add five for dew, will give thirty inches of water raised annually: 2*dly*, That the evaporation increases nearly, though not exactly, in the same ratio as the rain; thus 1797 gave most rain, and the greatest evaporation, &c.: 3*dly*, That there is little difference between the evaporation from bare earth of sufficient depth, and that from ground covered with grass. It is however to be observed, that the numbers in the last or right hand column belong to the years 1799, 1800, and 1801; and that on account of accidents with the frost, these numbers are partly conjectural for January, February, March, April, and December. The mean annual evaporation during the same three years from ground covered with grass, exclusive of dew, was 23·5 inches, which falls a little short of that for the other three, which was twenty-five.

But there is reason to suspect that a less depth of soil in the vessel would have allowed more water to escape into the bottles, and *vice versa*. It is therefore in some degree a matter of conjecture that this apparatus indicated the true evaporation from the adjacent fields. Lahire having filled a vessel eight feet deep with soil, and sunk it into the earth, left it there for fifteen years. It had an opening at the bottom for the escape of the water, but never a drop came through. The quantity of rain, to be sure, being less at Paris than at Manchester, will so far account for this.

In such an article as this it might be expected that, in conformity with custom, we should state the mean evaporation for all England, and a number of other principal countries. This however we are unable to do, because we are persuaded that to obtain even an approximate estimate would require experiments, such as those of Dr Dalton from the soil, to be made at least within every square mile of surface. The usual estimates being only derived from a vessel with water, as will be noticed more particularly afterwards, afford no measure of evaporation from the soil.

The following relation between the temperature and the rate of evaporation from water, was discovered by Dr Dalton. Having, as above mentioned, determined experimentally the force through a considerable range, he was naturally led to examine whether the quantity of water evaporated in a given time bore any proportion to the force of vapour of the same temperature, and was agreeably surprised to find that they corresponded in every part of the range examined. Thus the forces of vapour at 212°, 180°, 164°, 152°, 144°, and 138°, are equal to 30, 15, 10, 7·5, 6, and 5 inches of mercury respectively; and the grains of water evaporated per minute are in the same ratio. This Dr Dalton considers as quite in conformity with the laws of mechanics; for the atmosphere seems by its inertia to obstruct the diffusion of vapour, which would otherwise be almost instantaneous, as in vacuo; but this obstruction, which is greater as the air is more dense, is overcome in proportion to the force of the vapour. Did the obstruction arise from the weight of the atmosphere, it would prevent any vapour from rising at temperatures lower than 212°; but according to Dr Dalton it is caused by the inertiæ of the particles of air, and is similar to that which water meets with in descending among pebbles.

The theory of evaporation was thus far settled so much the more easily, because the force of vapour already in the open air being very small compared with what is produced from water at high temperatures, did not sensibly affect the results; but Dr Dalton found, that if the theory was to be verified by experiments for low temperatures, regard must be had to the force of vapour already in the atmosphere. For instance, if water of 59° were the subject, the force of vapour at that temperature being a sixtieth of the force at 212°, one might expect the quantity of evaporation to be a sixtieth also; but if it should happen, as it sometimes does in summer, that an aqueous atmosphere to that amount does already exist, the evaporation, in place of a sixtieth, would be nothing at all. On the other hand, if the previously existing vapour were the 120th, corresponding to 39° F., then the effective evaporating force would be the 120th of that from boiling water. In short, Dr Dalton found that the evaporating force must in every case be equal to that at the temperature of the water diminished by that already existing in the air. To find the force of the aqueous atmosphere, Dr Dalton revived the method which had been employed by Leroy long before. He used in summer to take a tall glass jar, and fill it with cold spring water, fresh from the well. If dew was immediately formed on the previously dry outside, he poured the water out, let it stand a little to rise in temperature, wiped dry the outside of the jar, and then poured the water in again. The like process is to be repeated till dew cease to be formed, and at that instant the temperature of the water is to be carefully noted, for the purpose of obtaining, from a table like that which shortly follows, the corresponding force of vapour. Such temperature is called the *dew point*, or the *point of deposition*; because the air, if cooled to it, would be in a state of saturation with moisture, and of course ready to deposit dew, especially on any thing in the least colder than itself. This operation should be performed in the open air, or at an open window, because the air within is generally more humid than without. Spring water in this country being generally within a degree or two of 50°, will mostly answer the purpose during the three hottest months; in other seasons an artificial cold mixture may be used. But Leslie's or Daniell's hygrometer would be still more convenient at all seasons.

To observe the evaporation at atmospheric temperatures, Dr Dalton had two light tin vessels; the one six inches diameter and half an inch deep, the other eight inches diameter and three fourths of an inch deep, and both made to be suspended from a balance. Water being put in one of these and weighed, it was placed in an open window or other exposed situation for ten or fifteen minutes, and again weighed to ascertain the loss from evaporation. The temperature of the water was at same time observed, the force of the aqueous atmosphere ascertained as above, and the velocity of the current of air noticed; for with the same evaporating force, a strong wind, by quickly changing the air in contact with the water, will double the effect produced in still air. From a great variety of experiments made during both winter and summer, and when the evaporating force was strong and weak, even in the case of ice, the results were found perfectly conformable with the theory. The same quantity is evaporated with the same evaporating force thus determined as near as can be judged, whatever be the temperature of the air. Thus, if the dew point be 40° while the air is at 60°, the evaporation is the same as if the dew point were at 60° and the air at 72°; for ·524 — ·263, which is the difference of the forces of vapour at 60° and 40°, is nearly equal to ·770 — ·524, the difference of the forces at 72° and 60°; but two such differences could be had exactly equal by using fractions of degrees of temperature, and interpolating between the other numbers.

The following table exhibits the ratios and quantity of water evaporated at different temperatures, derived from the preceding theory, and confirmed by experiments. The first column is the temperature; the second the force of vapour; the rest give the number of grains evaporated from a surface six inches in diameter, supposing the air to be previously dry. The third column is calculated on the supposition that at the temperature of 212° the evaporation per minute from the said surface is 120 grains; the fourth, that it is 154 grains; the fifth, 189, according to the strength of the wind; for if the air in contact with the water be continually changed, so that the recently moistened portion may be speedily removed and drier air substituted for it, the process will be proportionably expedited. These columns present the extremes and mean of evaporation likely to be noticed when the process goes on in air of the ordinary density. The effects of different densities will be considered afterwards.

As an example of the use of the table, let the dew-point be 52°, the temperature of the air 65°, with a moderate breeze, to find the evaporation per minute from a vessel six inches in diameter. The number in the fourth column opposite 52° in the first, is 2·06, and that opposite 65° is 3·16; the difference, 1·1 grain, is the evaporation required. Again, if the evaporation per minute, with a brisk wind, be 1·7 grain, while the air is at 62°; required the weight of the aqueous atmosphere, and the dew-point. In the fifth column the number opposite 62° is 3·52, being the whole evaporating force at that temperature in perfectly dry air, from which 1·7 being deducted, leaves 1·82, which, in the fifth column, is opposite to ·294 inch of mercury in the second, the weight of the column of vapour, and to 43° the temperature or dew-point. That is by using the nearest numbers in the table. Greater exactness may be had by interpolating between them. In this case, for instance, the weight should more correctly be ·290, and the dew-point 42°·6. Such estimates, however, are liable to uncertainty, where any doubt remains respecting the velocity of the wind.

Dr Dalton found that the same theory held with regard to the evaporation of other liquids, and was even more easily verified by experiment in their case than in that of water, on account of the air previously containing little or none of their vapours. In short, the evaporation in their case is similar to that of water in perfectly dry air.

Since vapours, so long as they maintain the gaseous form, expand and contract by change of temperature precisely at the same rate as air does in like circumstances, and since mixtures of air and vapour do the same, it follows, that if at any temperature above the dew-point the pressure of the unconfined air have to that of the vapour in it a certain ratio, it will have the same ratio to it at any other temperature not lower than the dew-point. Hence, because the entire pressure is constant, the force of vapour at the actual temperature of the air is exactly equal its force at the dew-point or temperature at which the air under the original pressure becomes saturated with moisture, and at which all the moisture in it just barely maintains the gaseous form.

Dr Anderson, in giving a table of the weight and force of aqueous vapour *in vacuo* (*Edin. Encyc.* xi. 578), says, it is adapted to a pressure of thirty inches, and that when the barometer differs from thirty, the numbers in the table (none of which denote atmospheres, but grains and inches) must be altered in the same ratio as the pressure. It is difficult to conceive how he could fall into such a palpable mistake. Vapour *in vacuo* being protected from atmospheric pressure, has obviously nothing to do with its changes or amount; and we have already seen that the maximum force and density of vapour in air, as well as *in vacuo*, depend solely on the temperature. Yet Dr Anderson (*ibid.* p. 581) makes the maximum weight of vapour which can exist in a cubic inch of air at a given temperature to be proportional to the barometric pressure, which is remarkable, considering his professed adherence to Dalton's theory. It is farther curious that the doctor, not perceiving that the actual force of vapour in the open air must be exactly equal to its force at the dew-point, gives (on same page) a formula for reducing the one force to the other; and he even takes it for granted that Dr Dalton is in the same error, though the very reverse appears from all his writings, and especially those already quoted.

The rate of evaporation is very different in air of different densities, being greater when the density is less, and *vice versa.* Some experiments on this subject are given by Professor Daniell, in the second and much improved edition of his valuable *Meteorological Essays*, published in 1827, page 493, from which we make the following brief abstract:—Upon the plate of an air pump was placed a flat dish 7·5 inches diameter, containing sulphuric acid, and covered by a receiver which but just passed over it, so that the base of the included air rested everywhere on the acid. In the middle of the dish was a stand supporting a vessel 2·7 inches diameter, and 1·3 deep, which was filled with water to the depth of an inch, and had a delicate thermometer resting on its bottom. The water, having been previously freed from air, was weighed with a very sensible balance, and then exposed to the action of the sulphuric acid. Its temperature was 45°, and the barometer at 30·4 inches. At the end of half an hour it was again weighed, and found to have lost 1·24 grain by evaporation. Having been replaced, and the air rarefied till the gauge stood at 15·2 inches, it was found to have lost in half an hour 2·72 grains, and to have had its temperature reduced to 43°. By repeating the process, continually diminishing the pressure one half, the successive losses from evaporation in intervals of half an hour each, were as follow:—

Pressure.	Temperature. Beginning.	Temperature. End.	Loss, Grains.
30·4	45°	45°	1·24
15·2	45	43	2·87
7·6	45	43	5·49
3·8	45	43	8·80
1·9	45	41	14·80
·95	45	37	24·16
·47	45	31	39·40

When the exhaustion was pushed to the utmost, which was ·07 inch, the evaporation in the half hour was 87·22 grains. During this last experiment the water was frozen in about 8 minutes, while the thermometer under the ice was at 37°. There must, however, be some inadvertency respecting the loss from evaporation in the second experiment; because in the table it is 2·87, and in the account before it only 2·72, which last, we presume, is the more correct of the two.

Before inferring from these experiments the rate of evaporation under different pressures, Mr Daniell applied to the results a correction for the variation of temperature. Taking the evaporation as proportional to the elasticity of the vapour, he estimated the latter from the mean of the temperatures at the beginning and end of each experiment, and calculated the amount for a fixed temperature. This might have been supposed to give a near approximation, were it not evident from the last experiment, that, owing to the bulb of the thermometer not being close at the evaporating surface, it indicated often too high a temperature; but the following table presents the results computed on that principle for the temperature of 45°; and here again we suspect the second number 2·97, being computed from 2·87, is too great.

Pressure.	Grains.
30·4	1·24
15·2	2·97
7·6	5·68
3·8	9·12
1·9	15·92
·95	29·33
·47	50·74
·07	112·32

Notwithstanding the slight irregularity of the series, Mr Daniell thinks we can run no risk in concluding that the amount of evaporation is, *cæteris paribus*, in exact inverse proportion to the elasticity of the incumbent air. But perhaps it would be more correct to say, that, *cæteris paribus*, the rate of evaporation is inversely as the *density* of the air; for that is Dr Dalton's view of the matter, and is equally conformable to these experiments. It may however be observed, that the rate of evaporation in the first case, which is in air of the ordinary density, is much smaller than that given by Dr Dalton; but the process going on in so small a volume of still and confined air, seems a sufficient reason for this.

Coolin influen of evap ration.

It was hinted above, that evaporation tends to lower the temperature of an evaporating surface, by abstracting heat from it for the formation of vapour. For, from the well known fact, that in the formation of aqueous vapour as much heat is absorbed as would raise the temperature of 1000 times its weight of water one degree, it follows, that were it not for the heat derived from surrounding bodies, the vaporization of the 1000th part of a mass of water would lower the temperature of the whole one degree; so that, by the time the 100th part had evaporated, the temperature of the whole would have fallen ten degrees. But surrounding bodies, particularly the air, by participating in the cooling effects, supply heat in such a manner to the water, that a limit is soon set to the fall of temperature. Although this cooling influence has been long known in a general way, it is remarkable how few experiments have been made, or, so far as we know, published, to show the extent of cold produced in different circumstances; and still more remarkable, that those few results of different experimenters should differ so widely, as we shall presently see they do. Dr Anderson, in the article *Hygrometry*, in the *Edinburgh Encyclopædia*, gives the following as the results of his experiments on the cold produced by the evaporation of water in air of different densities. For this purpose he placed Leslie's hygrometer, along with a cup of sulphuric acid, under a receiver of the air pump.

Dr Anderson's experiments.

29·6	48°·5	43°·64	4°·86	27°
23·6	48 ·5	42 ·38	6 ·12	34
17·6	48 ·5	40 ·58	7 ·92	44
11·6	48 ·5	37 ·34	11 ·16	62
5·6	48 ·5	32 ·12	16 ·38	91

The first column is the pressure in inches, the second the Fahrenheit temperature of the dry bulb, the third that of the moist, the fourth their difference or the depression, and the fifth the same depression in degrees of Leslie's hygrometer. The third and fourth columns, though not in the original, are obviously obtained from the others, and inserted in degrees of Fahrenheit, for the sake of comparison with those which follow.

In an article on hygrometers and evaporation, in the *Edinburgh Philosophical Journal* for October 1826, Mr Meikle gives the two following series of similar experiments, which were not made with Leslie's hygrometer, but with what was reckoned preferable for the purpose, two common thermometer tubes fitted upon one broad and doubly graduated scale; the one bulb being dry and the other covered with wet linen. The columns respectively denote the same things as the first four in Dr Anderson's.

Mr Meikle's experiments.

29·7	48°·2	36°·6	11°·6
19·4	47 ·3	33 ·2	14 ·1
17·2	47 ·2	32 ·5	14 ·7
13·3	47 ·0	31 ·2	15 ·8
8·8	46 ·4	27 ·2	19 ·2
29·9	60°·6	45°·5	15°·1
20·0	59 ·5	41 ·0	18 ·5
10·0	58 ·9	34 ·1	24 ·8
5·6	58 ·5	28 ·0	30 ·5

All sealed thermometers stand too low when the pressure of the atmosphere is removed from their bulbs. The two just mentioned were found to be each 1°·5 too low in an exhausted receiver. Hence most of the numbers in the second and third columns still require to be more or less corrected for this, according to the degree of exhaustion; but since both thermometers were equally affected, the depressions have nothing to do with it. However, the included air seems to have been really a little cooled from the influence of the cold wet bulb.

We have always been puzzled to account for the extreme smallness of Dr Anderson's depressions in the fourth column. Perhaps he had used very weak sulphuric acid, or too small a surface of it; or he might not be aware that the full effect in a single case is seldom attained in less than half an hour. The pressure and temperature in his first case are nearly the same as in Mr Meikle's; and yet the depression 4°·86 is not half of 11°·6. From many trials we know that the weather is by no means very droughty, if a wet thermometer do not fall more than 4°·86, when only exposed in the open air at 48°·5, without any sulphuric acid at all. To increase the cold in a wet thermometer, Dr Lardner recommends exposing it to the sun. But whoever takes the trouble of properly trying this, will find that the sun has quite the contrary effect; and therefore the doctor is just in the same delusion, only on a greater scale, when he directs his readers to wrap wine bottles in wet cloth, and expose them to the sun as a source of greater cold! The sun, like the fire, aids evaporation, by supplying heat, which will more or less counteract the cooling effect, and may even raise the temperature; but common sense revolts at the very idea of the heating rays of the sun being a source of cold.

In 1827, Professor Daniell published, in the second edition of his *Essays*, p. 499, a series of experiments on the cooling effects of evaporation, and which, like Mr Meikle's, were made by means of two common thermometers, the one dry and the other moist; but he seems only to have read off to the nearest half degree; and his depressions, though not so deficient as those of Dr Anderson, still lean considerably to the same side. The following are his results, arranged as the preceding:

Mr Daniell's experiments.

30·2	50°	41°	9°
15·1	49	37	12
7·5	49	34	15
3·7	49·5	31·5	18
1·8	49·5	28·5	21
.9	49	24·5	24·5
·4	49	23	26

From repeated experiments we have found that at the temperature of 50°, and under a pressure of about thirty inches, a wet thermometer, when inclosed in a receiver along with a sufficiently large surface of strong sulphuric acid, should fall 12°·1 or 12°·2, in place of 9°, as Mr Daniell has it. The rest of his depressions are still more deficient; but when we attend to the disposition of his apparatus, our surprise rather is that the depressions should be so great as they are. What we particularly object to is his not only inclosing a vessel with water under the receiver, but interposing it directly between the wet bulb and the sulphuric acid. This he did for the purpose of occasionally dipping that bulb in the water; a precaution which was not only unnecessary, but which, by rendering the air moist and obstructing the drying of the bulb, must obviously have rendered the whole of his depressions much smaller than they should have been in perfectly dry air. When Mr Meikle made his experiments, and they were published before those of Mr Daniell, he satisfied himself that if the thermometer was properly covered and moistened at first, no renewal of moisture was necessary. This he ascertained by repeating, in a retrograde order, the different cases when he had just completed a series of these experiments; for on finishing with the case in which the air was most rarefied, he readmitted as much air as just brought back the gauge to the next case, which being repeated, he readmitted more air for the next, and so on, till he had got back over the whole series. In every case, the wet thermometer was found to be as much depressed in the backward process as in the forward, a clear proof that there was no lack of moisture. Neither Dr Anderson nor Professor Daniell say whether they made any allowance for the effects of pressure on the bulbs of their thermometers.

Cold not yet observed in vaporizing turpentine.

Oil of turpentine is well known to evaporate very quickly, but we have as yet failed to detect any cold that it produces, though we do not therefore suppose it forms any exception to the general law. Some liquids, as alcohol, ether, sulphuret of carbon, &c. both evaporate more rapidly than water does, and produce a greater cold; but the expenditure of heat is greater in vaporizing a given weight of water than of any other liquid yet examined; a fact from which it had often been concluded that alcohol could be vaporized with so much less fuel than water, that its vapour would be an economical substitute for steam as a first mover; nay, this had become a standard doctrine in almost every scientific compilation. It however involved a fatal oversight, as was first pointed out by Mr Meikle in the *Philosophical Magazine* for July 1826, p. 41, and afterwards by Mr Ainger in Brande's *Journal of Science* for March 1830; for it is not with equal *weights*, but with equal *volumes* of these vapours, that the comparison falls to be made; and when this is done, the greater rarity of steam puts it on at least an equal footing with alcoholic vapour, so far as regards the economy of heat. In other respects, steam is decidedly preferable; for, independently of the enormous expense of alcohol, the density of its vapour, being about 2·5 times that of steam, would prevent it from moving with the same facility through the pipes, valves, &c.

Perhaps it may not be altogether foreign to our subject to mention, that Mr Hutton froze alcohol by condensing air on it in a strong vessel, which being very much cooled by freezing mixtures, was next suddenly opened, when the dilatation of the air, and the consequently rapid evaporation and re-expansion of the alcohol, absorbed so much heat as induced a cold sufficient to freeze it.

The bad effects of damp clothes, beds, &c. are usually ascribed to the cold attending the evaporation of the damp; but since considerable injury often follows where scarcely any cold is felt, we suspect the chief cause lies rather in the moisture suppressing the natural evaporation from the skin. The heavy smell which accompanies most dogs, and the fetid grease upon their hair, show that they perspire in some other shape besides what some suppose the only one from their tongues.

Various instruments have been employed to measure the rate at which moisture escapes into the atmosphere. We have already alluded to the method of exposing water in a vessel, and noting the loss. The vessel is generally circular, with a roof a little above it to keep off the rain, &c.; and, for greater accuracy, the contents may either be weighed from time to time, or measured in a graduated tube. When the vessel is brim full, the wind is apt to blow some of the water over; and when not full, the water is in some measure sheltered from the drying effects of the wind. The only use of such an instrument or gauge is to give us a very vague idea of the drying power of the air. It affords no measure whatever of the evaporation from the ground; for when the soil is exceedingly parched, and consequently has next to no moisture to give off, the gauge generally shows the greatest evaporation of all. Yet in stating the particulars of the climate of a place, it is usual to mention the amount of evaporation derived most probably from no better source. But it cannot even be a measure of the evaporation from a lake, because in that case the indications of the gauge depend very much on the direction of the wind; for it is obvious that if a previously dry wind traverse an extensive lake before reaching the gauge, it may by that time have become so humid as to show little or no drying power at all upon the gauge. When, on the other hand, the wind passes first over the gauge, its indications are to be suspected of erring in excess, because the farther a wind continues to traverse the surface of a lake, the more will its drying power be impaired, and therefore the average rate of evaporation will be less than at the side next the gauge. For this reason the evaporation from a smaller surface of water is, *cæteris paribus*, greater in proportion to the area than from a larger. Whether any general rule could readily apply to this, we are unable to say. Perhaps something like an approximation to the relation between the area and evaporation in such circumstances would be had by dividing the area by some root of its mean linear dimension taken in the direction of the wind, and multiplying by a constant. But this would not in the least rectify the indications of the gauge. Since similar objections must obviously attach to all gauges employed for this purpose, it would be of little use to give any farther account of them, or of the registers of evaporation with which many works otherwise valuable are so often encumbered.

No uria-
tic d in
sea r.

It had been long supposed that muriatic acid vapour existed in the atmosphere incumbent over the ocean or on the sea coasts; and various effects were ascribed to its presence. But from experiments detailed in the *Journal de Pharmacie* for November 1833, it appears that such effects are solely owing to minute drops of salt water or spray which have been swept into the atmosphere by the wind; and that, with the exception of the salt drops thus raised, though only when the sea is ruffled by the wind, sea-air contains neither muriates nor uncombined muriatic acid. At first sight we had some doubt whether this would account for the injurious effects of sea-air on vegetation; because the presence of common salt, if not in excess, is known to be beneficial. But perhaps the salt when united with the soil may operate as a cordial to the roots, while it may be noxious when in immediate contact with the stem or leaves, as is often the case with manure injudiciously applied close to the roots of plants.

diat .

In the method of forming ice in India by exposing water during the night to the aspect of a clear sky, the effect was for some time ascribed to evaporation; but Dr Wells ascertained that the water thus exposed gained in place of losing weight. Now it could only gain by being cooled below the dew point of the incumbent air; for it is only in that state that the air could yield a portion of its moisture to the water; and therefore the cold must be the effect of radiation, and not of evaporation. This was farther evident from the circumstance that wind which ought to have increased the evaporation prevented the freezing altogether. But independently of these considerations, water exposed in the open air could never be cooled to the freezing point by evaporation alone in a hot climate. Where such a thing occurs, the air must be unusually dry, even after its temperature scarcely amounts to 40°, or the atmospheric pressure must be very small; because the utmost evaporation that can be produced artificially under the ordinary pressure will little more than cool a wet thermometer from 40° to 32°; and the cooling effect on a vessel with water is not nearly so great, especially in the open air, if care be taken to avoid the influence of radiation under the aspect of a clear sky. It is true that, at Benares for instance, the surface of the ground, after becoming very cold by radiation, sometimes renders the incumbent still air also pretty cold; but this, by bringing the air to a state of saturation with moisture, totally unfits it for aiding the freezing by evaporation.

So great is the difference of opinion respecting the influence of electricity on evaporation, that we suspect it has not yet been sufficiently investigated. The use of evaporation in the arts and manufactures will be found under the respective articles. In addition to the various works noticed in this article, see Dr Thomas Young's *Natural Philosophy;* Wells *on Dew;* Pouillet's *Elemens de Physique et de Météorologie.* A variety of articles on this subject will be found in the different volumes of the *Philosophical Transactions*, and other scientific journals. (E. E. E.)

EVATES, a branch or division of the Druids, or ancient Celtic philosophers. Strabo divides the British and Gaelic philosophers into three sects; Bards, Evates, and Druids. He adds that the Bards were the poets and musicians, the Evates the priests and naturalists, and the Druids were moralists as well as naturalists. But Marcellus and Hornius mention only two sects, the Bards and Druids.

EVE, the mother of all mankind, who, being deluded by the serpent, occasioned the fall, with all its consequences.

EVELYN, John, a distinguished naturalist and writer on various subjects, was born at Wotton in Surrey, on the 31st of October 1620. In the fifth year of his age he was sent to Lewes in Sussex, where he was placed under the superintendence of his grandfather. The latter, however, having died in 1627, Evelyn in the following year was sent to learn his "Latin rudiments, and to write." In 1637, he entered as a student in Baliol College, Oxford; and in 1640 he removed to the Middle Temple, London. But his studies were interrupted by the civil commotions of this period; and about a year after his arrival in the Temple, he left England for the Continent. He returned in 1642; but the rupture between the king and the parliament had now assumed a serious aspect; loyalty could no longer be professed with safety; and in the year following, having asked and obtained the king's leave of absence, he became an exile, and spent several years in travelling through France and Italy. His powers of observation appear to have been great; and the curious and useful information which he thereby acquired constitutes the charm of many of his works, particularly of his diary. In 1647 he married the only daughter of Sir Richard Browne, the king's minister at Paris, in whose right he acquired the mansion of Sayes Court, near Deptford. This matrimonial alliance was a happy one. In his wife he possessed a woman of an enlightened mind, and of dispositions congenial with his own. That Evelyn must have conducted himself with more than ordinary prudence and discretion, appears evident; for whilst he thus allied himself with Sir Richard Browne, the ambassador of King Charles II. at Paris, he possessed several personal friends at the court of Cromwell, and in fact returned to England a few months after his marriage. Here he remained till 1649, when he again departed for the Continent; but returned to England in 1651. His manners, we may presume, were very agreeable, for his company was sought by the most eminent foreigners; and during his travels he made acquaintance not only with individuals distinguished for their learning, but with ingenious men belonging to every art and profession.

After his final settlement in his native country, Evelyn engaged in literary pursuits. His first undertaking was a translation from the French; and from the period of its publication to the close of a long life, he continued to give to the world original works replete with information alike useful, entertaining, and philosophical. These will be afterwards enumerated. After the death of Cromwell he interested himself in the restoration of Charles II., for which he was much favoured by that monarch, after his resumption of the royal prerogative. In 1660–61 he was nominated by his majesty one of the council, and chosen by the rest of the members a Fellow of the Philosophical Society, which met at Gresham College. This institution formed the basis of the Royal Society, which was established about two years afterwards, and to which Evelyn read a treatise on forest trees. This discourse formed the foundation of his most celebrated production entitled *Sylva.* In 1664 Evelyn was appointed one of the commissioners of the sick and wounded, and likewise a commissioner for rebuilding St Paul's Cathedral. When the board of trade was established by Charles II. Evelyn was nominated one of the members; and on this occasion he drew up a tract on navigation and commerce. In the reign of James II. he was one of the commissioners for executing the office of privy seal during the absence of the Earl of Clarendon in Ireland. He continued in favour at court even after the revolution, and was made treasurer of Greenwich Hospital, the foundation stone of which he laid in the year 1696. By the death of his elder brother in 1699, he succeeded to the paternal estate, and quitted Sayes Court for Wotton, where he passed the remainder of his life, excepting occasional visits to London, where he died on the 27th of February 1705–6, in the eighty-sixth year of his age.

In his personal character Evelyn was truly amiable. He discharged the relative duties of father, husband, and friend, in an exemplary manner; and during his long and useful, rather than splendid career, numerous offices of trust were reposed in him; nor was this confidence misplaced. His correspondence with foreigners as well as Englishmen was so extensive, that it is surprising he should have found time for examining what was deemed worthy of curiosity or of scientific observation, and for composing the great variety of works which he published. "His life," says Horace Walpole, "was a course of inquiry, study, curiosity, instruction, and benevolence. The works of the Creator, and the minute labours of the creature, were all objects of his pursuit. He unfolded the perfection of the one, and assisted the imperfection of the other. He adored from examination, was a courtier that flattered only by informing his prince, and by pointing out what was worthy for him to countenance; and really was the neighbour of the gospel, for there was no man that might not have been the better for him. Whoever peruses a list of his works will subscribe to my assertion. He was one of the first promoters of the Royal Society, a patron of the ingenious and the indigent, and peculiarly serviceable to the lettered world; for, besides his writings and discoveries, he obtained the Arundelian library for the Royal Society. Nor is it the least part of his praise that he who proposed to Mr Boyle the erection of a philosophical college for retired and speculative persons, had the honesty to write in defence of active life against Sir George Mackenzie's *Essay on Solitude.* He knew that retirement, in his own hands, was industry and benefit to mankind, but in those of others, laziness and inutility." The principal works of Mr Evelyn are, 1. An Essay on the First Book of Lucretius, in English verse, 8vo; 2. The French Gardener, 12mo; 3. *Fumifugium*, or the Inconveniences of the Air and Smoke of London dissipated, 4to; 4. Sculpture, or the History and Art of Chalcography and Engraving in Copper, 8vo; 5. *Sylva*, or a Discourse of Forest Trees; to which is added Pomona, concerning Fruit Trees, folio. In 1776 a new edition of the *Sylva* was published by Dr Hunter of York, and again in 1812. 6. A Parallel of the Ancient Architecture with the Modern, folio; 7. *Calendarium Hortense*, or the Gardener's Almanac, 8vo; 8. Public Employment and an Active Life preferred to Solitude, 8vo; 9. An Idea of the Perfection of Painting, 8vo; 10. A Discourse on the History of Trade and Navigation; 11. *Terra*, a Philosophical Discourse of Earth, 8vo; 12. *Numismata*, or a Discourse of Medals, folio. The Memoirs of Evelyn, comprehending an interesting diary and correspondence, were published in 1819, 2 vols. 4to, and more recently in 5 vols. 8vo. His miscellaneous works have also been collected and given to the public. They include treatises on gardening, architecture, medals, &c. besides a curious tract entitled *Mundus Muliebris; or the Ladies' Dressing Room unlocked, and the Toilette spread, in burlesque; together with the Fop's Dictionary, or Catalogue of Hard Names and Terms of the Art Cosmetick*, first printed in 1690.

EVERGETES, or EUERGETES, a surname signifying *benefactor*, given to Philip of Macedonia, to Antigonus Doson, and to Ptolemy of Egypt. It was also commonly applied to the kings of Syria and Pontus; and we often find among the former an Alexander Evergetes, among the latter a Mithridates Evergetes. Some of the Roman emperors also claimed the title of Benevolent.

EVESHAM, a market and borough town of Worcestershire, in the hundred of Blakenhurst, 96 miles from London. It is finely situated in the midst of the rich vale of the same name, on both sides of the river Avon. A great number of market gardeners in the vicinity raise large quantities of the rarer vegetables, but especially of asparagus, for the supply of Oxford, Birmingham, and other large towns. It returns two members to parliament, chosen by the freemen. The market is held on Monday. The population amounted in 1801 to 2837, in 1811 to 3068, in 1821 to 3487, and in 1831 to 3991.

EVIDENCE, in *Philosophy*, that perception of truth which arises either from the testimony of the senses or from an induction of reason.

EVIDENCE, in *Law*, signifies some proof by testimony of men upon oath, or by writings or records. See ENGLAND, Part III. *Government and Laws.*

EVIL, in *Philosophy*, is either moral or natural. Moral evil is the disagreement between the actions of a moral agent and the rule of those actions, whatever it is. Natural evil is whatever destroys or any way disturbs the perfection of natural beings, such as blindness, disease, and death.

King's EVIL, or *Scrofula.* See MEDICINE.

EVORA, a city of Portugal, in the province of Alemtejo. It is the seat of an archbishop, and is well fortified, though the fortifications are now of no possible use as means of defence. There is a most superb aqueduct, which conveys fresh water to the city from the distance of four or five miles. A college, or rather university, was established here in 1553; but it has gradually dwindled away, and is now almost extinct. This city contains 3000 houses and 12,000 inhabitants; and in its neighbourhood are many Roman ruins, particularly one of a temple to Diana. Lat. 38. 28. N.

EVREMOND, CHARLES DE ST DENIS, a polite scholar and soldier, was born at St Denis le Guast in Lower Normandy in 1613. He was intended for the profession of the law, and commenced study with this view; but he soon quitted it, and became an ensign before he was sixteen. A military life, however, did not prevent him from cultivating literature, and he signalized himself by his politeness and wit as much as by his bravery. The king made him a mareschal-de-camp, and gave him a pension of three thousand livres per annum. He served under the Duke of Candale in the war of Guienne, and in Flanders, till the suspension of arms was agreed on between France and Spain; and he afterwards accompanied Cardinal Mazarin when he went to conclude the peace with Don Louis de Haro, the king of Spain's first minister. He wrote, as he had promised, to the Marquis de Crequi, a long letter concerning this negotiation, in which he showed that the cardinal had sacrificed the honour of France to his own private interest, and rallied his eminence in a very satirical manner. This letter having fallen into the hands of the cardinal's friends some time after the death of that minister, it was represented as a state crime, and the author was obliged to fly to Holland. But he had too many friends in England, whither he had the year before accompanied the Count de Soissons, in order to compliment Charles II. upon his restoration, to make any long stay in Holland; and therefore he passed over into England, where he was received with great respect, admitted into the intimate friendship of several persons of distinction, and honoured with a pension of L.300 a-year. But he had a great desire to revisit his native country; and, after the peace of Nimeguen, he wrote a letter in verse to the king of France, to ask leave to return, but in vain. Upon the death of King Charles he lost the pension which had been conferred on him; and he did not rely much on King James, though that prince had been extremely kind to him. But the Revolution proved more advantageous to him than might have been expected. King William, who had known him in Holland, gave him substantial marks of favour. But he died of a stranguary in 1703, at the age of ninety, and was interred in Westminster Abbey, where a monument is erected to his memory. His behaviour was engaging, and his humour cheerful, but he had a strong disposition to satire. He professed the Roman Catholic religion, in which he was born; but at bottom he was believed to be a freethinker. He always spoke of his disgrace with the resolution of a gentleman; and however strong a desire he may have had to return to his country, he never solicited the favour with meanness; so that, when permission was unexpectedly granted to him in the decline of his life, he replied, that the infirmities of age did not permit him to leave a country where he had lived agreeably. There have been many editions of his works; but the best is that of Amsterdam in 1726, in 5 vols. 12mo, to which is prefixed his life by Dr des Maizeaux, who has also given an accurate English translation of them in 3 vols. 8vo.

EVREUX, an arrondissement of the department of the Eure, in France, extending over 1936 square miles. It comprehends eleven cantons and one hundred and twenty-two communes, inhabited by 122,401 inhabitants. The capital is a city of the same name, situated in a valley on the river Iton, some branches of which run through the streets. The town is well built, and has a fine Gothic cathedral and bishop's palace, the old castle of Navarre, and fine walks on what were once the ramparts. It contains 1094 houses and 9238 inhabitants, who are occupied in spinning twist, in making cotton, linen, and woollen goods, hosiery, paper, and leather. Long. 1. 3. 34. E. Lat. 49. 1. 24. N.

EWANPILLY, a Mahratta town and small port of Hindustan, in the province of Berar, 110 miles S.S.E. from Nagpoor. Long. 80. 55. E. Lat. 18. 50. N.

EWELL, a market-town of Surrey, in the hundred of Copthorne, thirteen miles from London. Near this town is the modernised ancient palace of Nonsuch, built by Henry VIII. and a favourite residence of Queen Elizabeth, but afterwards given by Charles II. to the Duchess of Cleveland. There is a market on Thursday, and a large annual fair, at which many thousand sheep are sold. The population amounted in 1801 to 1112, in 1811 to 1135, in 1821 to 1550, and in 1831 to 1851.

EX, or EXE, a river of England, which rises in a barren tract of land called Exmoor, in the county of Somerset, and after being enlarged by several accessions, passes Tiverton, Exeter, and Topsham. It next receives the waters of the Kew, and falls into the sea at Exmouth. This river is navigable by vessels of considerable burden to Topsham, and was so to Exeter formerly.

EXAGGERATION, in *Rhetoric*, a kind of hyperbole, by which things are augmented or amplified by saying more than the truth, either as to good or bad.

EXAGGERATION, in *Painting*, a method by which the artist, in representing things, changes them too much, or makes them too strong, either in respect of the design or the colouring. It differs from *caricaturing*, inasmuch as the latter perverts or gives a turn to the features of a face, or the figure, which they have not; whereas exaggeration only heightens or improves what they had.

EXALTATION, or ELEVATION, is chiefly used in a figurative sense, for the raising or advancing a person to some ecclesiastical dignity, particularly to the papacy.

EXALTATION of the Cross is a feast of the Roman Catholic church, held on the 14th of September, in memory, as is generally supposed, of the emperor Heraclius having brought back the true cross of Jesus Christ on his shoulders, in order to place it on Mount Calvary, from which it had been carried away fourteen years before by Cosroes, or Khusru, king of Persia, at his taking of Jerusalem, under the reign of the emperor Phocas. The cross was delivered up by a treaty of peace made with Siroe, the son and successor of Khusru. The institution of this treaty is commonly said to have been signalized by a miracle; inasmuch as Heraclius could not stir out of Jerusalem with the cross whilst he had the imperial vestments on, enriched with gold and precious stones, but bore it with ease in a common dress.

The feast of the dedication of the temple built by Constantine was, according to Nicodemus, held on the 14th of September, the day on which the temple had been consecrated in the year 335; and this feast was also called the *exaltation of the cross*, because it formed part of the ceremonial for the bishop of Jerusalem to ascend a high place, built for the purpose by Constantine, in manner of a pulpit, and called by the Greeks the *sacred mysteries of God*, or *the holiness of God*, and there to elevate the cross, that all the people might see it.

EXALTATION, in *Astrology*, is a dignity which a planet acquires in certain signs or parts of the zodiac, and which is supposed to give it an extraordinary virtue, efficacy, and influence. The opposite sign, or part of the zodiac, is called the dejection of the planet. Thus the 15th degree of Cancer is the exaltation of Jupiter, according to Albumazor, because it was the ascendant of that planet at the time of the creation; that of the sun is in the 19th degree of Aries, and its dejection in Libra; that of the moon is in Taurus; and so on.

EXAMINATION, an exact and careful search or inquiry, in order to discover the truth or falsehood of a thing.

Self-EXAMINATION is a point much insisted on by divines, and particularly the ancient fathers, by way of preparation for repentance. St Ignatius reduces it to five points, a returning thanks to God for his benefits; a begging of grace and light, to know and distinguish our sins; a running over all our actions, occupations, thoughts, and words, in order to learn what has been offensive to God; a begging of pardon, and conceiving a sincere sorrow for having displeased him; and making a firm resolution not to offend him any more, and taking the necessary precautions to preserve ourselves from sin.

EXARCH, in *Antiquity*, an appellation given by the emperors of the East to certain officers sent into Italy, in quality of vicars, or rather prefects, to defend that part of Italy which yet remained under their obedience, particularly the city of Ravenna, against the Lombards, who had made themselves masters of nearly all the rest of the country.

The residence of the exarch was at Ravenna, which city, together with that of Rome, was all that remained to the emperors. The first exarch was the patrician Boetius, famous for his treatise *De Consolatione Philosophiæ*, who was appointed in 568 by the younger Justin. The exarchs subsisted about 185 years, and ended with Eutychius, under whose exarchate the city of Ravenna was taken by the Lombard king Astulphus, or Astolphus.

The emperor Frederick created Heraclius, archbishop of Lyons, a descendant of the illustrious house of Montboissier, exarch of the whole kingdom of Burgundy; a dignity till that time unknown except in Italy, particularly in the city of Ravenna.

Homer, Philo, and other ancient authors, give the name *exarchus* to the choragus or master of the singers in the ancient choruses; the word *αρχω* or *αρχομαι* signifying equally to *begin* and to *commend*.

Exarch *of a Diocese* was, anciently, the same with primate. This dignity was inferior to the patriarchal, yet greater than the metropolitan.

Exarch also denotes an officer, still subsisting in the Greek church, being a kind of deputy or legate *a latere* of the patriarch, whose office it is to visit the provinces allotted him, in order to inform himself of the lives and manners of the clergy, and to take cognizance of ecclesiastical causes, the manner of celebrating divine service, the administration of the sacraments, particularly confession, the observance of the canons, monastic discipline, affairs of marriages and divorces, and, above all, the revenues which the patriarch receives from several churches, with the collection of the same. The exarch, after having greatly enriched himself in his post, frequently rises to the patriarchate itself.

Exarch is also used, in the ecclesiastical antiquities of the Eastern church, for a general or superior over several monasteries, as an archimandrite, who is exempted by the patriarch of Constantinople from the jurisdiction of the bishops, in the same manner as are the generals of the Roman Catholic monastic orders.

EXAUCTORATIO, in the Roman military discipline, differed from the *missio*, which was a full discharge, and took place after a soldier had served in the army twenty years; whereas the *exauctoratio* was only a partial discharge. The *exauctorati* lost their pay indeed, but still remained under their colours or *vexilla*, though not under the *aquila* or eagle, which was the standard of the legion; and hence, instead of *legionarii*, they were called *subsignani*, and were retained till they had either served their full time or had lands assigned them. The *exauctoratio* took place after a soldier had served seventeen years.

EXCALCEATION, amongst the Hebrews, was a particular law, by which a widow, whom her husband's brother refused to marry, had a right to summon him to a court of justice, and, upon his refusal, to excalceate him; that is, to pull off one of his shoes and spit in his face, both of which actions inferred great ignominy.

EXCELLENCY, a title anciently given to kings and emperors, but now to ambassadors, generals, and other persons, who are not entitled to that of *highness*, but yet are elevated above the other inferior dignities.

EXCENTRIC, in *Geometry*, a term applied to circles and spheres which have not the same centre, and consequently are not parallel; in opposition to concentric, where they are parallel, having one common centre.

EXCENTRICITY, in *Astronomy*, is the distance of the centre of the orbit of a planet from the centre of the sun; that is, the distance between the centre and the focus of the ellipse.

EXCESS, in *Arithmetic* and *Geometry*, is the difference between any two unequal numbers or quantities, or that which remains after the lesser is taken from the greater.

EXCHANGE.

In political economy the term exchange is commonly employed to designate that species of mercantile transactions by which the debts of individuals residing at a distance from each other are either partially or wholly liquidated, without the intervention of money. The object of this article is to explain the nature of these transactions, and the principles on which they are founded.

This will be best effected by treating, *first*, of the exchange between different parts of the same country; and, *secondly*, of that between different and independent countries.

Inland Exchange.

Inland exchange.

Suppose a merchant of London orders his agent in Glasgow to purchase and send to him a thousand pounds worth of cottons; then, although it should not suit the Glasgow merchant to commission goods of equal value from his London correspondent, the latter may nevertheless be under no necessity of remitting cash to Glasgow to discharge his debt. Among cities, or countries, having a considerable intercourse together, the debts mutually due by each other are found, in ordinary cases, to be nearly equal. And, therefore, the Glasgow merchant, who has shipped the cottons for London, does not transmit the bill drawn by him on his correspondent for their price directly to London to be cashed, for that would subject him to the expense of conveying the money home from London to Glasgow, but he gets its value from *some other merchant in Glasgow*, who has payments to make in London, on account of teas, wines, &c. imported from that city, and who, unless he could procure such a bill, would be obliged to remit their price in money. The bill on account of the cottons is, therefore, either drawn in favour of the person to whom the money for the tea and wine is owing in London, or it is drawn in favour of the tea merchant in Glasgow, and indorsed to him; and this last person, by presenting the bill to the purchaser of the cottons, receives its value, and consequently the price of the cottons, and the price, or part of the price, of his tea and wine, at the same moment. By this simple contrivance the expense and risk attending the double transmission, first, of money from London to Glasgow to pay the cottons, and, second, of money from Glasgow to London to pay the teas and wines, is entirely avoided. The debtor in one place is changed for the debtor in the other; and both accounts are settled without the intervention of a single farthing.

The bill drawn and negotiated in such a transaction as this is termed an *inland* bill of exchange. If the transaction had taken place between London or Glasgow and a foreign city, it would have been termed a *foreign* bill of exchange.

A bill of exchange may, therefore, be defined to be, "an order addressed to some person residing at a distance, directing him to pay a certain specified sum to the person in whose favour the bill is drawn, or his order."[1]

Circu stance which termi the pr of inl bills o chang

The price of bills of exchange fluctuates according to the abundance or scarcity of them in the market, compared with the demand. Thus, to revert to our former example, if we suppose the debts reciprocally due by London and Glasgow to be equal, whether they amount to L.10,000, L.100,000, or any other sum, they may all be discharged without the agency of money, and the price of bills of exchange will be at PAR; that is, a sum of L.100

---

[1] In mercantile phraseology, the person who draws a bill is termed the *drawer;* the person in whose favour it is drawn the *remitter;* the person on whom it is drawn the *drawee*, and after he has accepted, the *acceptor*. Those persons into whose hands the bill may pass previously to its being paid, are, from their writing their names on the back, termed *indorsers;* and the person in whose possession the bill is at any given period, is termed the *holder* or *possessor*.

or L.1000 in Glasgow will purchase a bill for L.100 or L.1000 payable in London, and *vice versa*. But if these two cities are not mutually indebted in equal sums, then the price of bills of exchange will be increased in the city which has the greatest number of payments to make, and will be proportionally reduced in that which has the fewest. If Glasgow owe London L.100,000, whilst the debts due by London to Glasgow only amount to L.90,000, it is clear, inasmuch as the merchants of Glasgow have a larger sum to remit to London than the merchants of London have to remit to Glasgow, that the price of bills on London would rise in Glasgow, because of the increased competition; and that the price of bills on Glasgow would fall in London, because of the proportionally diminished competition. And hence a larger sum would be required to discharge any given amount of debt due by Glasgow, and a less sum would be required to discharge a corresponding amount of debt due by London; or, which is the same thing, the exchange would be in *favour* of London, and *against* Glasgow. Bills on London would sell in Glasgow for a *premium*, and bills on Glasgow would sell in London at a *discount*, the amount of the premium in the one case, and of the discount in the other, being obviously equal.

On the supposition that the balance of L.10,000, due by Glasgow, depressed the exchange of that city on London *one per cent.*, it would at first sight appear as if it would cost Glasgow L.101,000 to discharge its debt of L.100,000 due to London; and that, on the other hand, L.89,108 would be sufficient to discharge the debt of London to Glasgow. But a very little consideration will serve to show that this could not really be the case. No exchange transactions can take place between different cities, until there be both debtors and creditors of the one residing in the other. And hence, when the exchange became unfavourable to Glasgow, the premium paid by the Glasgow merchants for bills drawn on London would not go into the pockets of their creditors in that city, but into the pockets *of their neighbours in Glasgow, to whom London was indebted*, and from whom the bills had been purchased. The loss to Glasgow would, therefore, be limited to the *premium* paid on the balance of L.10,000. Thus, supposing that A of Glasgow owes D of London L.100,000, and that C of London owes B of Glasgow L.90,000; A will pay to B L.91,000 for a bill, or order, on C to pay D L.90,000. In this way, the L.90,000 London debt at Glasgow would be quite cleared off; the premium, which is lost by the debtor to London in Glasgow, being gained by its creditor in the same place. If the business had been transacted in London, C, with L.89,108, would have purchased of D a bill for L.90,000 payable by A, so that, in this case, the gain would have fallen to the share of the debtor C, and the loss to that of the creditor D, both of London. The complexity of real transactions does not affect the principles on which they are founded; and to whatever extent Glasgow might be indebted to London, or London to Glasgow, the only disadvantage under which either of them would in consequence be placed, would be the unavoidable one of paying the expense of remitting the *balance* of debt.

Natu limit fluct tions the exch ge.

The expense of transmitting money from one place to another forms the natural limit to fluctuations in the exchange. If 20s. sufficed to cover the expense and risk attending the transmission of L.100 from Glasgow to London, it would be indifferent to a Glasgow merchant, whether he paid one per cent. *premium* for a bill of exchange on London, or remitted money direct to that city. If the premium were less than one per cent. it would be clearly his interest rather to make his payments by means of bills of exchange than by remittances; and that it could not exceed one per cent. is obvious, for every individual would rather directly remit money, than incur an unnecessary expense, by purchasing a bill on London at a greater *premium* than would suffice to cover the expense of a money remittance. If, owing to the badness of the roads, to disturbances in the country, or to any other cause, the expense of remitting money from Glasgow to London should be increased, the difference in the rate of exchange between them *might* also be proportionally increased. But in every case, the extent to which this difference could attain would necessarily be limited by, and could not, for any considerable period, exceed, the cost of making remittances in cash.

Exchange transactions become more complex, when one place, as is very often the case, discharges its debts to another by means of bills drawn on a third place. Thus, although London should owe nothing to Glasgow, if Glasgow be indebted to London, London to Manchester, and Manchester to Glasgow; Glasgow would either wholly or partially discharge its debt to London by a bill drawn on Manchester. It would wholly discharge it, provided the debt due to Glasgow in Manchester was equivalent to the debt due by Glasgow to London. But if this be not the case, Glasgow must either remit money to London to discharge the *balance* of debt, or bills drawn on some other place indebted to her.

Transactions in inland bills of exchange are almost entirely conducted by bankers, who charge a certain rate per cent. for their trouble, and who, by having a credit in those places to which they are in the habit of remitting bills, are enabled, on all occasions, to supply the demands of their customers. In Great Britain, London, because of its intimate connection with other parts of the country, occasioned partly by its immense commerce, partly by its being the seat of government, and the place to which the revenue is remitted, and partly by its currency consisting of Bank of England paper, for which the paper currency of the country banks is rendered exchangeable, has become the great focus in which all the money transactions of the empire centre, and in which they are ultimately adjusted. In consequence of these various circumstances, but chiefly of the demand for bills on London to remit revenue, and of the superior value of Bank of England currency, the exchange between London and the other parts of the country is invariably in its favour. Bills on London drawn in Edinburgh and Glasgow were formerly made payable at forty days' date, which is equivalent to a *premium* of about one half per cent.; but, owing to the greater facility of communication, this *premium* is now reduced to twenty days' interest, or to about one fourth per cent. Bills for remitting the revenue from Scotland are now drawn at thirty days; previously to 1819 they were drawn at sixty days.

What has been already stated is sufficient to show, that, however well fitted bills of exchange may be for facilitating the operations of commerce, and saving the trouble and expense attending the transportation of money, it is impossible to adjust mercantile transactions by their means, except in so far as the accounts mutually balance each other. A *real* bill of exchange is merely an order entitling the holder to receive payment of a debt *previously contracted* by the person on whom it is drawn. It is essential to the existence of such a bill that an equivalent amount of debt should first be due. And hence, as the amount of the real bills of exchange drawn on any number of merchants cannot exceed the amount of their debts, if a greater sum be owing them than they owe to others, the *balance*, it is obvious, must either be paid in money, or by the delivery of some sort of commodities. If, as in the example just given, Glasgow owe London L.100,000, while London only owes Glasgow L.90,000, a reciprocal transfer of debts may be made to the extent of L.90,000. But the Glasgow merchants cannot discharge

Inland Exchange.

the additional L.10,000 by means of bills drawn on London; for, by the supposition, London only owed them L.90,000, and they have already drawn for its amount. The balance, therefore, must be discharged by an actual money payment, or by the delivery of some species of commodity, or by bills drawn on some third party who may be indebted to Glasgow.

Fictitious bills of exchange.

We do not mean by this to insinuate that there are no *fictitious* bills of exchange, or bills drawn on persons who are not really indebted to the drawer, in the market. In every commercial country, bills of this description are always to be met with; but they are only a device for obtaining loans, and do not and cannot transfer real debts. A merchant in London may form a connection with a merchant in Glasgow, and draw bills of exchange upon him payable a certain number of days after date, which the latter may retire by selling in Glasgow an equal amount of bills drawn upon his correspondent in London. The merchants who purchase, or the bankers who discount these bills, really advance their value to the drawers, who, as long as they continue, by means of this system of *drawing* and *redrawing*, to provide funds for their payment, continue in fact to command a borrowed capital equal to the amount of the fictitious paper in circulation. It is clear, however, that the negotiation of such bills has no effect in the way of transferring and settling the real *bona fide* debts reciprocally due between any two or more places. Fictitious bills mutually balance each other. Those drawn by London on Glasgow are exactly equal to those drawn by Glasgow on London, for the one set is drawn to pay the other—the second destroys the first, and the result is nothing.

The method of raising money by the discount or sale of fictitious bills, has been severely censured by Dr Smith, as entailing a ruinous expense on those engaged in it, and as being resorted to only by projectors, or persons of suspicious credit. When fictitious bills are drawn at two months' date, it is common, in addition to the ordinary interest of five per cent. to charge a commission of one half per cent., which must be paid every time the bill is discounted, or, at least, *six* times in the year. The total expense of money raised in this way could not, therefore, supposing the transaction to be always on account of the same individual, be estimated at less than eight per cent. per annum; and the payment of so high a rate of interest on borrowed capital, in a country where the ordinary rate of mercantile profit is only supposed to average from *six* to *ten* per cent., could not fail to be generally productive of ruin to the borrower. It seldom happens, however, that in transactions carried on by means of fictitious bills, the whole charge for commission falls on one individual. Loans obtained in this way are almost always on account of two or more persons. Thus, at one time a fictitious bill may be drawn by A of London on B of Glasgow; and, in this case, the Glasgow merchant will, before the bill becomes due, draw upon his London correspondent for the proceeds of the bill, including interest and commission. At another time, however, the transaction will be on account of B of Glasgow, who will then have to pay commission to his friend in London; so that each party may, on the whole, as Mr Thornton has observed, gain about as much as he pays in the shape of commission.

It is often extremely difficult to distinguish between a fictitious bill and one which has arisen out of a real mercantile transaction. Neither does it seem to be of any very material importance. The credit of the persons whose names are attached to the bills offered for discount, is the only real criterion by which either a private merchant or a banker can judge whether he ought to negotiate them. The circumstance of a merchant offering considerable quantities of accommodation paper for discount, ought, unquestionably, if discovered, to excite suspicions as to his credit. But unless in so far as the drawing of fictitious bills may be held to be indicative of over-trading, or of a deficiency of capital to carry on the business in which the party is engaged, there does not appear to be any good reason for refusing to discount them.

These few observations will, perhaps, suffice to explain the manner in which transactions between different parts of the same country are settled by means of bills of exchange. They are, in general, extremely simple. The uniform value of the currency of a particular country renders all comparison between the value of money at the place where the bill is drawn and negotiated with its value where it is to be paid, unnecessary; while the constant intercourse maintained amongst the different commercial cities of the same kingdom, by preventing those derangements to which the intercourse between distant and independent countries is always subject, prevents those sudden fluctuations which so frequently occur in the market price of foreign bills of exchange. We shall, therefore, leave this part of our subject, and proceed to investigate the circumstances which influence the course of exchange between different and independent countries.

Foreign Exchange.

The price of foreign bills of exchange depends entirely on two circumstances, *first*, on the value of the currency at the place where they are made payable, compared with the value of the currency at the place where they are drawn; and, *secondly*, on the relation which the supply of bills in the market bears to the demand.

If the real and nominal value of the currencies of the different nations having an intercourse together remained invariable, such fluctuations in the price of bills of exchange as arise from the first of these circumstances would be altogether unknown. But as the comparative value of the pound sterling, dollar, franc, guilder, florin, &c. is subject to perpetual variation, the price of bills of exchange must vary accordingly. Such variations, however, as proceed from this cause, affect merely their *nominal*, or rather numerical value. It is those only which arise from variations in the supply and demand for bills, or, which is the same thing, in the payments a country has to make compared with those it has to receive, that can be considered as *real*; and hence the distinctions of *nominal*, *real*, and *computed* exchange. The *first* depends on alterations in the value of the currencies compared together; the *second* depends on the supply of bills in the market compared with the demand; and the *third* or *computed* exchange depends on the combined effects of the other two. For the sake of perspicuity we shall treat of these separately.[1]

SECT. I.—NOMINAL EXCHANGE.

Bullion being everywhere recognised as the standard currency of the commercial world, the comparative value of the currencies of particular countries must depend, *1st*, on the value of bullion in those countries; and, *2dly*, on the *quantity* of bullion contained in their coins, or on the quantity of bullion for which their paper money, or other circulating media, will exchange.

---

[1] Supposing every country to be in possession of its proper supply of bullion, the exchange may be said to be *nominally* affected by the amount of the difference between the market and mint price of bullion, and to be *really* affected by any deviation from par exceeding or falling short of that difference.

I. The real price of commodities being always proportioned not merely to the cost of their production, but also to the cost of their conveyance from where they have been produced to where they are to be made use of, it follows, that if the trade in the precious metals were perfectly free, and if the commodities produced in different countries were nearly all equally well fitted for exportation, the value of bullion in different countries would be chiefly regulated by their respective distances from the mines. Thus, on the supposition that neither England nor Poland had any other commodities except corn to exchange with the South Americans for bullion, it is evident that the precious metals would possess a greater value in Poland than in England, because of the greater expense of sending so bulky a commodity as corn the more distant voyage, and because of the greater expense of conveying the gold to Poland. If Poland, however, had succeeded in carrying her manufactures to a higher pitch of improvement than England, her merchants might be able, notwithstanding the disadvantage of distance, by exporting commodities possessed of great value in small bulk, and on which the expense of freight would be comparatively trifling, to sell bullion on cheaper terms than those of England. But if, as is actually the case, the advantages of skill and machinery were possessed by England, another reason would be added to that derived from her less distance from the mines, why gold and silver should be less valuable in England than in Poland, and why the money price of commodities should be higher in the former. (Ricardo, *Principles of Political Economy*, &c. 1st ed. p. 175.)

Hence, after nations have attained to different degrees of excellence in manufacturing industry, the value of bullion in different countries no longer depends entirely on their distance from the mines. But, whatever variations a different progress in the arts may occasion in the value of bullion in different countries, it is certain that it must always be less valuable in those into which it is imported, than in those where it is produced. Bullion, like every other commodity, *is exported to find, not to destroy its level.* And unless its value in Europe exceeded its value in America by a sum sufficient to cover the expenses attending its importation, and to yield the ordinary rate of profit to the importer, we should not, although the mines of Mexico and Peru were infinitely more productive, import from them a single ounce of bullion. It is obviously incorrect, therefore, to lay down as a general proposition, "that the par of exchange between two countries is that sum of the currency of either of the two, which, in point of intrinsic worth, is precisely equal to a given sum of the other, *that is, contains precisely an equal weight of gold and silver of the same fineness.*" (*Bullion Report*, p. 22, 8vo ed.) For a given quantity of gold and silver is not always, as is here assumed, of the same intrinsic value in different countries. It may not, indeed, differ very materially among nations in the immediate vicinity of each other, and which are all destitute of mines. But although, to use a familiar illustration, the value of sugar approaches nearly to a level in the great trading cities of Europe, it cannot surely be maintained that its value in the West Indies is the same with its value in Bordeaux or Liverpool, or that the exchange would be really at par, if a bill, which cost a hundred hogsheads of sugar in London, only brought a hundred in Jamaica. Now, this is precisely the case with bullion. Though the value of gold and silver, as compared with corn, labour, &c. may, and indeed must, vary very considerably among the different European nations, these variations are only the necessary result of their different progress in industry, and of the different quality of their cultivated lands, &c. Such differences of price are in the natural order of things; and bullion has only found its proper level when a quantity has been introduced into those countries which excel in manufactures, sufficient to raise the price of their corn and labour. These variations have, therefore, no effect on the exchange. An ounce of bullion in one country, notwithstanding this difference of price, will, because of the facility of intercourse, be very near equivalent to an ounce of bullion in another; and, supposing the trade in the precious metals to be perfectly free, the exchange will be at true par when bills are negotiated on this footing. But when we compare the values of the precious metals in distant countries, and especially in those where they are produced, with those into which they are imported, it is obvious they must differ considerably. Gold and silver, like iron, coal, tin, &c. are necessarily cheaper in countries possessed of extraordinarily productive mines, than in those possessed only of mines of a secondary degree of fertility, or when they have to be entirely imported from abroad. And the exchange between such places is not at true par, unless adequate allowance be made for this difference of value. Thus, if, because of the expense of carriage, the value of bullion in Great Britain is five per cent. greater than in Rio Jeneiro, a hundred ounces of pure gold in Rio Janeiro would not be worth a hundred ounces of pure gold in London, but five per cent. less; and the exchange would be at true par when bills for a hundred and five ounces of standard bullion payable in Rio Janeiro, sold in London for a hundred ounces.

The differences in the value of the precious metals in different countries have not been confined to those depending on their respective distances from the mines, or on their different progress in the arts. The opinion formerly so very prevalent, that gold and silver were the only articles that constituted real wealth, induced almost every commercial nation to fetter and restrict their exportation, and to adopt a variety of measures intended to facilitate their importation. But these regulations, even when most rigorously enforced, have been singularly ineffectual; the great value and small bulk of the precious metals rendering it not only extremely advantageous, but also comparatively easy, clandestinely to export them, whenever their relative value declined.

"When," says Dr Smith, "the quantity of gold and silver imported into any country exceeds the effectual demand, no vigilance of government can prevent their exportation. All the sanguinary laws of Spain and Portugal are not able to keep their gold and silver at home. The continual importations from Peru and Brazil exceed the effectual demand of those countries, and sink the price of these metals *below* their price in the neighbouring countries. If, on the contrary, in any particular country their quantity fell short of the effectual demand, so as to raise their price *above* that of the neighbouring countries, the government would have no occasion to take any pains to import them. If it were even to take the pains to prevent their importation, it would not be able to effect it. Those metals, when the Spartans had got wherewithal to purchase them, broke through all the barriers which the laws of Lycurgus opposed to their entrance into Lacedæmon. All the sanguinary laws of the customs are not able to prevent the importation of teas of the Dutch and Gottenburg East India Companies, because somewhat cheaper than those of the British Company. A pound of tea, however, is about a hundred times the bulk of one of the highest prices, 16s., that is commonly paid for it in silver, and more than two thousand times the bulk of the same price in gold, and is consequently just so many times more difficult to smuggle." (*Wealth of Nations*, vol. ii. p. 149.)

But, however ineffectual as a means of entirely preventing the egress of the precious metals, the restrictions on their exportation have nevertheless contributed to occasion some slight variations in their value in different countries. The risk incurred by the clandestine exporters of bullion from Spain is supposed to be equivalent to about two per cent.; or, which is the same thing, it is supposed that the restrictions maintain such an excess of gold and silver in that country as to sink their value two per cent. below their value in countries having a free trade in bullion. In calculating the true par of exchange between Spain and other countries, this circumstance must be taken into account. For to whatever extent the value of bullion in one country may be reduced below its value in those with which it maintains an intercourse, the nominal exchange must necessarily be unfavourable to that extent.[1]

It consequently results, that whatever occasions a rise or fall in the value of the precious metals in a particular country, must proportionally affect its nominal exchange with other countries. If more coin, or convertible paper, circulated in Great Britain, compared with the business it has to perform, than what circulates in other countries, its relative value would, in consequence, be diminished. Foreign bills would sell for a premium, the amount of which would be precisely equal to the excess of the value of the precious metals in the foreign market, caused by their redundancy in the home market; and, on the other hand, in the event of the currency becoming relatively deficient, its value would be proportionally increased;—bills drawn on foreign countries would sell at a discount, the amount of which would measure the excess of the value of the currency of this over that of other countries.

Manner of estimating the quantity of bullion contained in the coins of different countries.

II. In estimating the quantity of bullion contained in the currencies of different countries, a particular coin of one country, such as the British pound sterling, is selected as an *integer* or standard of comparison, and the proportion between it and the coins of other countries, supposing them to be of their *mint standard weight and fineness*, is ascertained by experiment. A par of exchange is thus established, or rather it is ascertained that a certain amount of the standard currency of a particular country contains precisely as much gold or silver of the same fineness, as is contained in the coin or integer with which it has been compared. This relation, or par as it is technically termed, is considered invariable; and allowance is made for subsequent variations in the quantities and purity of the bullion contained in the currencies of countries trading together, by rating the exchange at so much above or below par. In mercantile language, that country, by a comparison with one or other of whose coins the par of exchange has been established, is said to give the *certain* for the *uncertain*, and conversely. Thus, in the exchange between London and Paris, London and Hamburg, &c. London gives the *certain*, or the pound sterling, for an *uncertain* or variable number of francs, florins, &c. Hence, the higher the exchange between any two countries, the more is it in favour of that which gives the *certain*, and the lower, the more is it in favour of that which gives the *uncertain*.

On the supposition, which is very near the truth, that twenty-five francs contain the same quantity of standard bullion as a pound sterling (twenty-five francs, twenty centimes, is the exact par), and supposing also that the value of bullion is the same in both countries, the exchange between London and Paris will be at par, when a bill drawn by a merchant in the one on his correspondent in the other sells at that rate; that is, when a bill of exchange for 2500 or 25,000 francs payable in Paris, sells in London for L.100 or L.1000, and *vice versa*. It is but seldom, however, that the coins of any country correspond exactly with their mint standard; unless, when newly issued, they are all either more or less worn; and whenever this is the case, an allowance corresponding to the difference between the actual value of the coins and their mint value must be made in estimating "*the sum of the existing currency of either of two countries which contains precisely the same quantity of bullion as is contained in a given sum of the other.*" Thus, if the one pound sterling were so worn, clipped, rubbed, &c. as not to contain so much bullion as twenty-five francs, but ten per cent. less, the exchange between London and Paris would be at real par when it was nominally ten per cent. against London;[2] and if, on the other hand, the pound sterling was equal to its mint standard, while the franc was ten per cent. less, the exchange between London and Paris would be at real par when it was nominally ten per cent. against Paris and in favour of London. If the currency of both countries were *equally* reduced below the standard of their respective mints, then it is obvious there would be no variation in the real par. But whenever the currency of countries trading together is depreciated in an *unequal* degree, the exchange is nominally in favour of that country whose currency is least depreciated, and nominally against that whose currency is most depreciated.

It is almost unnecessary to refer to the history of exchange to show the practical operation of this principle; and we shall content ourselves with selecting the following, from an infinite number of equally conclusive instances.

In a pamphlet printed in 1604, but written in 1564, it is mentioned, that when Henry VIII. degraded the several species of coin then current, there began to be "*some disorder*" in the price of all wares and commodities, which Edward VI. attempted to remedy by diminishing still farther the quantity of pure silver contained in each coin; the consequence was, that *the English pound sterling, which heretofore exchanged abroad for twenty-six Flemish schillings, became worth no more than thirteen Flemish schillings*, the price of English commodities being at the same time proportionally increased. (Mr John Smith's *Memoirs of Wool*, vol. i. p. 105, 8vo. ed.)

Previously to the great re-coinage in the reign of William III., silver being at that time a legal tender, the *nominal* exchange between England and Holland, calculated according to the standard of their respective mints, was twenty-five per cent. against England; but inasmuch as English silver coins were then, owing to rubbing and clipping, depreciated more than twenty-five per cent. below their mint value, the real exchange may notwithstanding have been in favour of England. The circumstance of the *nominal* exchange having become favourable to this country as soon as the new coin was issued, renders this conjecture extremely probable. (*Wealth of Nations*, vol. ii. p. 215.)

Before the reformation of our gold coin in 1774, the guinea contained so much less than its standard weight as

---

[1] All restraints on the exportation of the precious metals were abolished in Great Britain in 1819. Their effect for many years previous could not be estimated at above one fourth per cent.

[2] It is necessary to observe, that it is here supposed that the clipped or degraded money exists in such a degree of abundance as only to pass current at its bullion value. If the quantity of clipped money were *sufficiently limited*, it might, notwithstanding the diminution of weight, pass current at its mint value; and then the par would have to be estimated, not by its relative weight to foreign money, but by the mint price of bullion. This is a principle which must be constantly kept in view.

No al Exc ge.

to be degraded from two to three per cent. when compared with the current French coins, and the exchange between England and France was computed to be two or three per cent. *against* this country. Upon the reformation of the gold coin the exchange rose to par. The Turkish government, in the course of the last forty years, has made three great alterations in the value of its coin. Before these frauds were committed, the Turkish *piastre* contained nearly as much silver as the English *half crown;* and, in exchange, the par was estimated at *eight* piastres to the pound sterling. The consequence of these repeated adulterations has been, the reduction of the silver in the piastre to one half, and a fall in the exchange of 100 per cent.; bills on London having been bought in Turkey, in 1803, at the rate of sixteen piastres for every pound sterling.[1] Now, although it is not absolutely certain that these fluctuations in the *nominal* exchange were entirely owing to the alterations in the value of the coin, because the real exchange, or that which depends on the abundance or scarcity of bills in the market, might not be constant; yet the exact correspondence of the fall of exchange with the acknowledged degradation of the coin, renders it more than probable that it proceeded almost entirely from that degradation.[2]

Effec of varia ns in th lative lue of ld and s r on th x- chang

When one country uses gold as the standard of its currency, and another silver, the par of exchange between them is affected by every variation in the relative value of these metals. When gold rises in value compared with silver, the exchange becomes nominally favourable to that country which has the gold standard, and *vice versa.* And hence, in estimating the state of the exchange among countries using different standards, it is always necessary to advert to the comparative values of the metals selected for standards.

"For example," to use the words of Mr Mushet, "if 34 schillings 11 grotes and ¼ of Hamburg currency be equal in value to a pound sterling, or 20/21 of a guinea, when silver is at 5s. 2d. per oz. they can no longer be so when silver falls to 5s. 1d. or 5s. an oz. or when it rises to 5s. 3d. or 5s. 4d.; because a pound sterling in gold being then worth more or less silver, is also worth more or less Hamburg currency.

"To find the real par, therefore, we must ascertain what was the relative value of gold and silver when the par was fixed at 34s. 11¼g. Hamburg currency, and what is their relative value at the time we wish to calculate it.

"For example, if the price of standard gold was L.3. 17s. 10½d. per oz. and silver 5s. 2d., an ounce of gold would then be worth 15·07 ounces of silver, and twenty of our standard shillings would then contain as much pure silver as 34s. 11 grotes and ¼ Hamburg currency. But if the ounce of gold were L.3. 17s. 10½d. and silver 5s. (which it was on 2d January 1798), the ounce of gold would then be worth 15·57 ounces of silver. If L.1 sterling at par, therefore, be worth 15·07 ounces of silver, then at 15·57 it would be at three per cent. premium; and three per cent. premium on 34s. 11¼d. is 1 schilling 1 grote and 9/10, so that the par, when gold is to silver as 15·57 to 1, will be 36 schillings 1 grote and 1/10. The above calculation will be more easily made by stating as '15·07 : 34-11¼ :: 15·57 : 36-1 1/10.'"[3]

Nominal Exchange.

Effect of seignorage on the exchange.

As it is by their intrinsic worth as bullion that the values of the coins of particular countries is estimated in exchange, two coins of equal weight and purity are reckoned equivalent to each other, although the one should have been coined at the expense of the state, and the other charged with a *seignorage,* or duty on its coinage. Coins on which a *seignorage* is charged may, if not issued in excess, pass current in the country where they are coined, at a value so much higher than their value in bullion; but they will not pass at any higher value in other countries.[4]

Effect of variations in the value of paper currency on the exchange.

But the principal source of fluctuations in the nominal price of bills of exchange is to be found in the varying value of the *paper* currency of commercial countries. The disorders which universally arose in rude ages from the diminution of the quantity of standard bullion contained in the coins of different countries are now reproduced in another form, and often to a still more ruinous extent, in the depreciation of their paper currency.

The impossibility of retaining a comparatively large quantity of coin or bullion, or of convertible paper, in a particular country, effectually limited the issues of the Bank of England previously to the Restriction Act of 1797, and sustained the value of our currency on a par with that of other countries. When the bank issued less paper than was necessary for this purpose, the value of the currency becoming relatively great, it became profitable to import bullion, and to send it to the mint to be coined. And, on the other hand, when the bank issued too much paper, and thereby depressed its value relatively to gold, it became profitable to demand payment of its notes, and thereafter to export the species thus obtained either in the shape of coin or as bullion. In this way the bank was compelled to limit its issues when excessive, and, consequently, to put a stop to the demand for gold, by rendering its paper of equal value.

Had the Bank of England, subsequently to the restriction, issued only such quantities of paper as were required to sustain its value on a par with the value of gold, the act of 1797 would not have occasioned any real difference in our monetary system. But after the bank had been released from the obligation to pay its notes, it was not to be expected that it should be very careful about limiting their number. The restriction *enabled* the directors to exchange bits of engraved paper, worth perhaps not more than five shillings a quire, for as many, or the value of as many hundreds of thousands of pounds. And under such circumstances, the only thing to be wondered at is, not that paper money became depreciated, but that its value was not more degraded,—that a still greater quantity of bank-notes were not forced into circulation.

A country with an inconvertible paper currency, of which an undue quantity has been issued, is in the same situation as a country would be in were it possessed of a redundant gold and silver currency, and subjected to laws prohibiting the melting or exportation of the coin that were carried into full effect. Such a currency is necessa-

---

[1] Il est impossible d'indiquer exactement le *pair* des monnoies Turques. On voit des pieces du même nom, et frappées la même année, qui different de 100 pour cent. dans leur valeur intrinsèque. (Storch, *Cours d'Economie Politique,* tom. vi. p. 336.)

[3] *An Inquiry into the Effects produced on the National Currency by the Bank Restriction Bill,* &c. by Robert Mushet, Esq.; second edit. p. 94.

[4] Previously to 1817, no seignorage had for a very long period been deducted from either the gold or silver coins of Great Britain; but in the great recoinage of that year the value of silver was raised from 5s. 2d. to 5s. 6d. an ounce, or nearly in the proportion of 6½ per cent. The gold coins, however, are still coined free of expense, and no variation has been made in their standard. The British mint proportion of silver to gold is now as 14 287/1000 to 1; that is, one ounce of standard gold bullion is rendered exchangeable for 14 287/1000 ounces of standard silver. In France the mint proportion of the two metals is as 15½ to 1; a seignorage being exacted of nearly ½d per-cent. on gold, and 1½ per cent. on silver.

Nominal Exchange.

rily confined to the country where it is issued; it cannot, when too abundant, diffuse itself generally amongst others. The level of circulation is destroyed; and the value of the currency becoming less than the value of the currency of other countries, the nominal exchange is rendered proportionally unfavourable.

Supposing that nothing but silver coin of the standard weight and purity (twenty-five francs of which would exchange for a pound sterling of the British mint standard) circulates at Paris, and that the circulating medium of London is composed entirely of paper only worth half its nominal value, or which is depreciated 100 per cent.; in that case the exchange between London and Paris would be at *real* par, when it was nominally cent. per cent. against London. Double the amount of such depreciated London currency would be required to purchase a bill of exchange on Paris where the currency retained its value, while half the former amount of Parisian currency would now suffice to purchase a bill payable in London. A depreciation of this sort would have exactly the same effects as an equal reduction in the value of metallic money. While paper money, depreciated 100 per cent. constituted our legal currency, a pound note, instead of being worth 25 francs, would only be worth $12\frac{1}{2}$; and the nominal or numerical value of the bills of exchange negotiated between this country and France would be regulated accordingly; that is, a bill of exchange for L.100 or L.1000 payable in London, would sell in Paris for 1250 or 12,500 francs, and conversely. If, while the currency of London remained steady at 100 per cent. below its mint value, Parisian currency should, either from the coins becoming deficient in weight, or because of an inordinate issue of paper money, become also depreciated, the *nominal* exchange would be rendered proportionally less unfavourable to London. On the hypothesis that the currency of Paris is depreciated 50 and that of London 100 per cent. the *nominal* exchange would be 50 per cent. against the latter, and so on. Thus it appears that the *nominal* exchange between any two or more places will always be adjusted according to the value of their currencies; being most favourable to that country whose currency approaches nearest to its mint standard, and most unfavourable to that whose currency is most degraded.

Exchange between Great Britain and Ireland subsequent to 1797.

The state of exchange between Great Britain and Ireland, subsequently to the restriction on cash payments in 1797, furnishes a striking proof of the effects which inordinate issues of paper have in depressing the exchange.

The nominal value of the Irish shilling having been raised from 12d. to 13d., or, which is the same thing, L.108. 6s. 8d. of Irish money having been rendered only equal to L.100 of British money, it followed, that when the exchange between Great Britain and Ireland was at $8\frac{1}{3}$ per cent. against the latter, it was said to be at par. In the *eight* years previous to 1797, when the paper currency both of England and Ireland was convertible into gold, the exchange between London and Dublin fluctuated from $7\frac{1}{2}$ to 9 per cent. that is, from $\frac{5}{6}$ per cent. in favour of Dublin, to $\frac{2}{3}$ per cent. against it. In September 1797 it was so low as 6 per cent., or $2\frac{1}{3}$ per cent. in favour of Dublin. The amount of Bank of Ireland notes in circulation in January 1797 was only L.621,917; but in April 1801 they had increased to L.2,286,471, and the exchange was then at 14 per cent., or $5\frac{2}{3}$ per cent. *against* Dublin. In 1803, the Bank of Ireland notes in circulation averaged L.2,707,956, and in October of that year the exchange rose to 17 per cent. that is, to $8\frac{2}{3}$ per cent. against Dublin!

The fact of the exchange between London and Dublin having fluctuated so very little from real par for eight years previous to the restriction, shows that the circulating medium of Great Britain and Ireland had then been adjusted nearly according to the wants of the two countries. But, in these circumstances, it was evidently impossible, supposing the value of British currency to remain stationary, that the quantity of Irish bank paper could be nearly *quintupled* in the short space of six years, without rendering the currency of Ireland comparatively redundant, and sinking its value below that of England. Had the Bank of England increased its notes nearly in the same ratio as the Bank of Ireland, then, as the currency of both countries would have been *equally depreciated*, the exchange between London and Dublin would have continued at par. But while the notes of the Bank of Ireland were increased from L.621,917 to L.2,707,956, or in the proportion of 1 to 4·3, those of the Bank of England were only increased from L.9,181,843 (their number on 7th January 1797), to L.16,505,272, or in the proportion of 1 to 1·8. If the Bank of England had not made this addition to its issues, the exchange would obviously have been still more unfavourable to Dublin.

In the debates on the Bullion Report, it was contended that the increase of Bank of Ireland paper could not be the cause of the exchange becoming unfavourable to Dublin, inasmuch as it had again become favourable to the latter, after the issues of the Bank of Ireland had been still further increased. Nothing, however, can be more inconclusive than such reasoning. To give it the least weight, it must be shown that the currency of Great Britain had in the interim retained its value, or that it had not been depreciated to the same extent as that of Ireland. Unless this be established, the circumstance that the exchange between London and Dublin came to par, while as many notes of the Bank of Ireland circulated as in the period of its greatest depression, will not authorise us to conclude that the increase of Irish bank paper was not the cause of the fall in the exchange previously to 1804. For it is obvious that the depreciation of Irish bank paper might be going on subsequently to 1804; and yet, supposing English bank paper had been depreciated still more rapidly, the exchange would become more favourable to Dublin. This is merely supposing the circumstances which took place in the first six years of the restriction to be reversed in the second six. Let us examine how the fact stands.

We have seen that, in 1803, when the exchange was nominally ten per cent. against Dublin, the issues of the Bank of England amounted to L.16,505,272, and those of the Bank of Ireland to L.2,707,956. And, by referring to the account of the issues of the Bank of Ireland from 1797 to 1819, annexed to the article MONEY in this work, it will be seen that, in 1805, 1806, 1807, and 1808, they were rather *diminished;* and that, in 1810, they only amounted to L.3,251,750, being an increase of not more than L.543,794 in the space of seven years, or at the rate of two and six-sevenths per cent. per annum; but in the same period (from 1803 to 1810) the issues of the Bank of England had increased from L.16,505,272 to L.22,541,523, or at the rate of five per cent. per annum. But this is not all. According to Mr Wakefield (*Account of Ireland*, vol. ii. p. 171), who has left no subject untouched which could throw light on the state of Ireland, there were *fifty* registered bankers in that country in 1804, and only *thirty-three* in 1810, of which fourteen were new houses, thirty-one of the old establishments having disappeared; and I believe," says Mr Wakefield, "*for the most part failed.*" This extraordinary diminution of the country paper of Ireland, for the reduction of the issues was at least proportional to the reduction in the number of banks, must have greatly raised its value, and would have countervailed a very great increase in the issues of the national bank. Now the very reverse of all this took place in Britain. In 1800 there were 386 country banks in this country; and in 1810, this number, instead of being diminished, as in Ireland, had increased to 721, having at least three times the number of notes in circulation in the latter as in the former period!

It appears, therefore, that when, in the period between 1797 and 1804, the quantity of paper in circulation in Ireland was increased, and consequently its value depressed, faster than in England, the exchange between London and Dublin became proportionally unfavourable to the latter; and, on the other hand, it appears, that when, in the six years subsequent to 1804, the paper currency of England was increased more rapidly than the paper currency of Ireland, its relative value was diminished, and the *nominal* exchange became more favourable to Dublin.

This is sufficiently conclusive; but there is still more decisive evidence to show that the unfavourable exchange of Dublin upon London in 1802, 1803, 1804, &c. was entirely owing to the comparative redundancy or depreciation of Irish bank paper. The linen manufacturers, weavers, &c. and the majority of the other inhabitants of a few counties in the north of Ireland, being, at the period of the restriction, strongly disaffected towards government, almost unanimously refused to receive bank notes, either in payment of commodities or as wages. The landlords, having also stipulated for the payment of their rents in specie, the consequence was, that a gold currency was maintained in the north of Ireland long after it had been entirely banished from the southern part of the island. If, therefore, the depressed state of the exchange between London and Dublin had been occasioned, as was contended by the advocates of the restriction, by an unfavourable balance of trade between Ireland and Great Britain, or by remittances from the former on account of absentee landlords, &c. it would have been equally depressed between London and the commercial towns in the northern counties. But, so far from this being the case, in December 1803, when the exchange of Dublin on London was at sixteen and one-fourth per cent. that of Belfast on London was at five and one-fourth; or, in other words, at the same time that the exchange between Dublin and London was about eight per cent. against Ireland, the exchange between Belfast, *which had a gold currency*, and London, was about three per cent. in its *favour*. Nor is this all. There was not only a difference of eleven per cent. in the rate of exchange between Dublin and London, and Belfast and London, but the *inland* exchange between Dublin and Belfast was, at the same time, about ten per cent. in favour of the latter; that is, bills drawn in Dublin, and payable in the gold currency of Belfast, brought a premium of ten per cent.; while bills drawn in Belfast, and made payable in the paper currency of Dublin, sold at ten per cent. discount.[1]

It is unnecessary to refer to the history of the French *assignats*, or of the paper currency of the continental powers generally, and of the United States, to corroborate what has been advanced. Such of our readers as wish for detailed information as to these points may have recourse to the fourth volume of the *Cours d'Economie Politique* of M. Storch, where they will find an able and instructive account of the effects produced by the issues of paper on the price of bullion and the exchange, in almost every country of Europe. They are, in every case, precisely similar to those now stated.

It only remains to determine the effects of fluctuations in the *nominal* exchange, on the export and import trade of the country.

Inquiry into the effects of fluctuations in the nominal exchange on export and import trade.

When the exchange is at par, the operations of the merchant are regulated entirely by the difference between foreign prices and home prices. He imports those commodities which can be sold at home for so much more than their price abroad as will indemnify him for the expense of freight, insurance, &c. and yield an adequate remuneration for his trouble, and for the capital employed in their importation; and he exports those whose price abroad is sufficient to cover all expenses, and to afford a similar profit. But when the *nominal* exchange becomes unfavourable to a particular country, the premium which its merchants receive on the sale of foreign bills has been supposed capable of enabling them to export with profit in cases where the difference between the price of the exported commodities at home and abroad might not be such as would have permitted their exportation had the exchange been at par. Thus, if the *nominal* exchange were ten per cent. against this country, a merchant who had consigned goods to his agent abroad would receive a premium of ten per cent. on the sale of the bill; and if we suppose freight, insurance, mercantile profit, &c. to amount to six or seven per cent. it would at first sight appear as if our merchants might, in such circumstances, export commodities although their price at home were three or four per cent. higher than in other countries. If, on the other hand, the *nominal* exchange were in our favour, or if bills *on* this country sold at a premium, it would appear as if foreigners would then be able to consign goods to our merchants, or our merchants to order goods from abroad, when the difference of real prices was not such as would of itself have led to an importation.

But a very little consideration will convince us that fluctuations in the *nominal* exchange can have no such effect. That fall in the value of the currency which renders the exchange unfavourable, and causes foreign bills to sell at a premium, must *equally increase* the price of all commodities. And hence, whatever might be the amount of the premium which the exporter gained by the sale of the bill drawn on his correspondent abroad, it would do no more than indemnify him for the enhanced price of the goods exported. Mercantile operations are in such cases conducted precisely as they would be were the exchange really at par; that is, by a comparison of the real prices of commodities at home and abroad, meaning, by real prices, the prices at which they would be sold provided there were no depreciation of the currency. If those prices be such as to admit of exportation or importation with a profit, the circumstance of the nominal exchange being favourable or unfavourable will make no difference whatever on the transaction.

"Suppose," says Mr Blake, who has very successfully illustrated this part of the doctrine of exchange, "the currencies of Hamburg and London being in their due proportions, and therefore the *nominal* exchange at par, that sugar, which, from its abundance in London, sold at L.50 per hogshead, from its scarcity at Hamburg would sell at L.100. The merchant in this case would immediately export. Upon the sale of his sugar he would draw a bill upon his correspondent abroad for L.100, which he could at once convert into cash by selling it in the bill market at home, deriving from this transaction a profit of L.50, under deduction of the expenses of freight, insurance, commission, &c. Now, suppose no alteration in the scarcity or abundance of sugar in London and Hamburg, and that the same transaction were to take place after the currency in England had been so much increased that the prices

---

[1] Farther information on this interesting subject may be obtained from the very able *Report of the Committee of the House of Commons*, appointed in 1804 to inquire into the state of the circulating paper in Ireland, its specie, &c. and the state of the exchange between it and Great Britain; in Sir Henry Parnell's excellent pamphlet on the same subject; and in the pamphlets of Lord King, Mr Huskisson, &c.

Nominal Exchange.

were doubled, and, consequently, the *nominal* exchange 100 per cent. in favour of Hamburg, the hogshead of sugar would then cost L.100, leaving apparently no profit whatever to the exporter. He would, however, as before, draw his bill on his correspondent for L.100; and, as foreign bills would bear a premium of 100 per cent. he would sell this bill in the English market for L.200, and thus derive a profit from the transaction of L.100 depreciated, or L.50 estimated in undepreciated currency, deducting, as in the former instance, the expense of freight, insurance, commission, &c.

"The case would be precisely similar, *mutatis mutandis*, with the importing merchant. The unfavourable *nominal* exchange would appear to occasion a loss amounting to the premium on the foreign bill which he must give in order to pay his correspondent abroad. But if the difference of *real* prices in the home and foreign markets were such as to admit of a profit upon the importation of produce, the merchant would continue to import, notwithstanding the premium; for that would be repaid to him in the advanced *nominal* price at which the imported produce would be sold in the home market.

"Suppose, for instance, the currencies of Hamburg and London being in their due proportions, and, therefore, the *nominal* exchange at par, that linen, which can be bought at Hamburg for L.50, will sell here at L.100. The importer immediately orders his correspondent abroad to send the linen, for the payment of which he purchases at L.50 a foreign bill in the English market, and on the sale of the consignment for L.100, he will derive a profit amounting to the difference between L.50 and the expense attending the import.

"Now, suppose the same transaction to take place without any alteration in the scarcity or abundance of linen at Hamburg and London, but that the currency of England has been so augmented as to be depreciated to half its value, the *nominal* exchange will then be 100 per cent. against England, and the importer will not be able to purchase a L.50 foreign bill for less than L.100. But as the prices of commodities here will have risen in the same proportion as the money has been depreciated, he will sell his linen to the English consumer for L.200, and will, as before, derive a profit amounting to the difference between L.100 depreciated, or L.50 estimated in undepreciated money, and the expenses attending the import.

"The same instances might be put in the case of a favourable exchange; and it would be seen in the same manner that *nominal* prices and the *nominal* exchange being alike dependent on the depreciation of currency, whatever apparent advantage might be derived from the former would be counterbalanced by a loss on the latter, and *vice versa*." (*Observations*, &c. p. 48.)

It appears, therefore, that fluctuations in the *nominal* exchange have no effect on export or import trade. A fall in the exchange obliges the country to which it is unfavourable to expend a larger *nominal* sum in discharging a foreign debt than would otherwise be necessary; but it does not oblige it to expend a greater *real* value. The depression of the *nominal* exchange can neither exceed nor fall short of the comparative depreciation of the currency. If the depreciation of British currency amounted to 10 or 100 per cent. the *nominal* exchange would be 10 or 100 per cent. against us; and we should be compelled, in all our transactions with foreigners, to give them 22s. or 40s. for what might otherwise have been procured for L.1. But as neither 22s. nor 40s. of paper, depreciated to the extent of 10 or 100 per cent. would be more valuable than L.1 of undepreciated paper, payment of a foreign debt might, it is evident, be as easily made in the one currency as in the other; and mercantile transactions would, in such circumstances, be conducted exactly as they would have been had the currency been undepreciated, and the *nominal* exchange at par.

It is necessary, however, before dismissing this part of our subject, to examine the effects of fluctuations in the *nominal* exchange on the importation and exportation of *bullion*. In certain cases they form an exception to the general principle we have been endeavouring to elucidate.

If the *nominal* exchange were unfavourable to a country which had entirely discarded the precious metals from its circulation, Mr Blake's opinion that the fall of the exchange has no effect on the export and import of bullion, more than of any other commodity, would be perfectly well founded. In this case the price of all sorts of commodities, and of bullion among the rest, would be increased precisely according to the depreciation of the currency; and the merchants who should, under such circumstances, attempt to export bullion, would find that its increased price in the home market would be exactly equivalent to whatever premium they might gain by the sale of the bills drawn on their agents abroad for its price. But when the *nominal* exchange becomes unfavourable to a country whose currency consists entirely of the precious metals, or partly of them and partly of paper, a different effect is produced.

In this case the depreciation necessarily adds to the stock of bullion in the country. For as soon as the currency has been depreciated to such an extent as to render the excess of the market above the mint price of bullion sufficient to cover the very trifling expenses attending the melting of the coin, and to afford some little remuneration for the trouble of the melters, they immediately set about converting it into bullion. If, indeed, it were possible to realize a greater profit by the exportation than by the fusion of the coins, they would not be converted into bullion, and, of course, its real price would continue stationary. But this is very seldom the case. The operation of melting is so extremely simple, and requires so very little apparatus, that it may, in almost every instance, be carried on at a less expense than would be necessary to export the coins. The cost attending the conveyance of gold to Paris varies in a season of peace, from one to two per cent.; while a profit of one fourth or one half per cent. is sufficient to indemnify the melters of guineas or sovereigns. It is obvious, therefore, that of the two modes of restoring the value of the currency when it becomes depreciated, or relatively redundant, that of fusion will be generally resorted to in preference to exportation. Should the redundancy of the currency be inconsiderable, all the addition which the operations of the melters could make to the supply of bullion, would most probably be insufficient to occasion any perceptible fall in its *real* price. But, in every case in which the redundancy or depreciation of the currency is considerable, the fusion of the coined money never fails to increase the quantity of bullion beyond the effectual demand, and, consequently, to occasion a fall in its *real* price, and to render it a profitable article of export. The demand for bullion, though it must always vary with the varying wealth and riches of the community, fluctuates very little in periods of limited duration; and no considerable addition can ever be made to the stock on hand in a particular country, without sinking its value and causing its egress.

Mr Blake contends that this exportation of bullion is the effect of the melting of the coin, and not the cause of it; and in so far he is certainly right. But we do not see how this in the least strengthens his opinion, that fluctuations in the *nominal* exchange, even in those cases in which the currency consists either wholly or partially of the precious metals, have no influence on the export and import of bullion. Surely it is impossible to deny that the fusion of the

al
ange.

coin, of which Mr Blake admits the exportation of bullion is a necessary consequence, is occasioned by a redundancy of the currency, or by the same cause which occasions an unfavourable *nominal* exchange.

Bullion, therefore, forms an exception, and it is the only one, to the general principle that a fall in the value of the currency, or an unfavourable *nominal* exchange, has no effect on importation or exportation. But this exception does not take place, except in those cases in which the currency consists either in *whole* or in *part* of the precious metals. When the currency consists *entirely* of paper, or of any commodity other than gold or silver, its depreciation has no influence whatever on the importation of bullion.

SECT. II.—REAL EXCHANGE.

Re ex-
cha e.

Having thus endeavoured to trace the effects which variations in the value of the currencies of countries maintaining an intercourse together have on the exchange, we now proceed to consider how far it is influenced *by fluctuations in the supply and demand for bills.* To facilitate this inquiry, we shall exclude all consideration of changes in the value of money; or, which is the same thing, we shall suppose the currencies of the different countries having an intercourse together to be all fixed at their mint standards, and that each has its proper supply of bullion.

When two nations trade together, and each purchases from the other commodities of precisely the same value, their debts and credits will be equal, and, of course, the real exchange will be at par. The *bills* drawn by the one are, in such a case, exactly equivalent to those drawn by the other, and their respective claims may be adjusted without the transfer of bullion, or other valuable produce. But it very rarely happens that the debts reciprocally due by any two countries are equal. There is almost always a balance owing on one side or other; and this balance must affect the exchange. If the debts due by London to Paris exceeded those due by Paris to London, the competition in the London market for bills on Paris would, because of the comparatively large sum which our merchants had to remit to France, be greater than the competition in Paris for bills on London; and, consequently, the *real* exchange would be in favour of Paris and against London.

Lim to
fluct
tion the
real
char

The expense of the transfer of bullion from one country to another constitutes the limit within which the rise and fall of the *real* exchange between them must be confined. In this respect, as in most others, transactions between foreign countries are regulated by the very same principles which regulate those between different parts of the same country. We have already shown how the fluctuations in the *real* exchange between London and Glasgow could never exceed the expense of transmitting money between those cities. The same principle holds universally. Whatever may be the expense of transmitting bullion,—the money of the commercial world,—between London and Paris, Hamburg, New York, &c., it is impossible that the *real* exchange of the one on the other should, for any considerable period, be depressed to a greater extent. For a merchant will not pay a greater premium for a bill to discharge a debt abroad, than would suffice to cover the expense of transmitting bullion to his creditor.

Hence it appears that whatever has a tendency to obstruct or fetter the intercourse among different countries, must also tend to widen the limits within which fluctuations in the *real* exchange may extend. This enables us to account for its varying so much more in time of war than in time of peace. The amount of the bills drawn on a country engaged in hostilities is, from various causes which we shall afterwards notice, liable to be suddenly increased, though it is certain that whatever may be the amount of the bills thus thrown upon the market, the depression of the exchange cannot, for any length of time, exceed the expense of conveying bullion from the debtor to the creditor country. But during war this expense is increased; the charges on account of freight, insurance, &c. being then necessarily augmented. It appears, from the evidence annexed to the *Report of the Bullion Committee*, that the expense of conveying gold from London to Hamburg, which, prior to the war, only amounted to two or two and a half per cent. had, in the latter part of 1809, increased to about seven per cent.; showing that the limits within which fluctuations in the real exchange were confined in 1809 were about three times as great as those within which they were confined in 1793.

Real
Exchange.

This principle also enables us to account for the greater steadiness of the real exchange between countries in the immediate vicinity of each other. The expense of transmitting a given quantity of bullion from London to Dublin or Paris, is much less than the expense of transmitting the same quantity from London to New York or Petersburg. And, as fluctuations in the *real* exchange can only be limited by the cost of transmitting bullion, they may consequently extend much farther between distant places than between those that are contiguous.

Inquiry into the circumstances which give rise to a favourable or an unfavourable balance of payments.

It will now be proper to investigate the circumstances which give rise to a favourable or an unfavourable balance of payments, and to appreciate their effects on the real exchange, and on the trade of the country in general. As this is one of the most important inquiries in the whole science of political economy, it will require to be discussed at some length.

The fact that the value of the imports exceeds that of the exports, does not warrant the conclusion that the balance of payments is unfavourable.

A very great, if not the principal, source of the errors into which practical merchants, and the majority of writers on the subject of exchange, have been betrayed, appears to have originated in their confounding the sum which imported commodities are worth in the home market, with the sum which they cost in the foreign market. It is obviously, however, by the amount of the latter only, that the balance of payments, and consequently the *real* exchange, is influenced. A cargo of iron, for example, which cost L.1000 free on board at Gottenburg, might be worth L.1200 or L.1300 when imported into England; but the foreign merchant would not be entitled to draw on London for more than its original cost, or L.1000. It is clear, therefore, on the slightest consideration, that the circumstance of the value of the imports exceeding the value of the exports, does not authorise the conclusion that the balance of payments is unfavourable. A favourable or an unfavourable balance depends entirely on the sum due *to* foreigners for commodities imported from abroad being less or more than the sum due *by* them for the commodities they have purchased; but it has nothing to do with the prices eventually obtained for the imported or exported commodities.

The great object of the *mercantile* system of commercial policy, a system which still continues to preserve a considerable influence in this and in every other country in Europe, is, the creation of a favourable balance of payments, and consequently of a favourable *real* exchange, by facilitating exportation and restricting importation. It is foreign to the object of this article to enter into any examination of the principles of this system, except in so far as they are connected with the subject of exchange; but we hope to be able to show, in opposition to the commonly received opinions on the subject, that, under ordinary circumstances, the value of the imports must always exceed the value of the exports; and that this excess of importation has not, speaking generally, any tendency to render the *real* exchange unfavourable.

It is the business of the merchant to carry the various

In countries carrying on an advantageous commerce, the value of the imports must always exceed the value of the exports.

products of the different countries of the world from those places where their value is least, to those where it is greatest; or, which is the same thing, to distribute them according to the effective demand. It is clear, however, that there could be no motive to export any commodity, unless the commodity which it was designed to import in its stead was of greater value. When an English merchant orders a quantity of Polish wheat, he calculates on its selling for so much more than its price in Poland as will be sufficient to pay the expense of freight, insurance, &c.; and to yield, besides, the common and ordinary rate of profit on the capital employed in the business. If the wheat did not sell for this sum, its importation would obviously occasion a loss to the importer. No merchant ever did or ever will export, but in the view of importing a greater value in return. And so far from an excess of exports over imports being any criterion of an advantageous commerce, it is quite the reverse; and the truth is, notwithstanding all that has been said and written to the contrary, that unless the value of the imports exceeded that of the exports, foreign trade could not be carried on. Were this not the case—were the value of the exports always greater than the value of the imports, merchants would lose on every transaction with foreigners, and the trade with them would either not exist at all, or, if begun, would be speedily relinquished.

In England, the rates at which exports and imports are valued were fixed so far back as 1696. But the very great alteration that has since taken place, not in the value of money only, but in the cost of most part of the commodities produced in this and other countries, has rendered this *official* valuation, though valuable as a means of determining their quantity, of no use whatever as a criterion of the true value of the imports and exports. To obviate this defect, an account of the *real* or *declared* value of the exports is annually prepared from the declarations of the masters, and laid before parliament. There is, however, no such account of the imports; and, owing to the difficulties which high duties throw in the way, it is, perhaps, impossible to frame one with any thing like accuracy. It has also been alleged, and apparently with some foundation, that merchants have not unfrequently exaggerated the value of articles entitled to drawbacks on exportation; but the recent extension and improvement of the warehousing system, and the decrease in the number of drawbacks, must materially lessen whatever fraud or inaccuracy may have arisen from that source. Indeed, as most articles are charged with an *ad valorem* duty of 10s. per cent. on exportation, the fair presumption is, that their value will be underrated. We believe, however, that the declared value of the exports comes pretty near the truth, at least sufficiently so for all practical purposes.

But if perfectly accurate accounts could be obtained of the value of the exports and imports, there can be no manner of doubt that in ordinary years the latter would always exceed the former. The value of an exported commodity is estimated when it is shipped, *before* its value is increased by the expense incurred in transporting it to the place of its destination; but the value of the commodity imported in its stead is estimated *after* it has arrived at its destination, and, consequently, after it has been enhanced by the cost of freight, insurance, importer's profit, &c.

It is of very little importance, in so far at least as the interests of commerce are concerned, whether a nation act as the carrier of its own imports and exports, or employ others. A carrying nation appears to derive a comparatively large profit from its commercial transactions; but this excess of profit is nothing more than a fair remuneration for the capital it employs, and the risk it incurs, in transporting commodities from one country to another. Were the whole trade between this country and France carried on in British bottoms, our merchants, in addition to the value of the goods exported, would also receive the cost of their carriage to France. This, however, would not occasion any loss to that country. The French merchants must pay the freight of the commodities they import; and if the English can afford it on cheaper terms than their own countrymen, there is no good commercial reason, though there may be others of a different kind, why they should not employ them in preference.

In the United States the value of the imports, as ascertained by the customhouse returns, always exceeds the value of the exports. And although our practical politicians have been in the habit of considering the excess of exports over imports as the only sure criterion of an advantageous commerce, "it is nevertheless true, that the real gain of the United States has been nearly in proportion as their imports have exceeded their exports."[1] The great excess of American imports has been in part occasioned by the Americans generally exporting their own surplus produce, and consequently receiving from foreigners, not only an equivalent for their exports, but also for the cost of conveying them to the foreign market. "In 1811," says the author just quoted, "flour sold in America for nine dollars fifty cents per barrel, and in Spain for fifteen dollars. The value of the cargo of a vessel carrying 5000 barrels of flour would, therefore, be estimated, at the period of its exportation, at 47,500 dollars; but as this flour would, because of freight, insurance, exporter's profits, &c. sell in Spain for 75,000 dollars, the American merchant would be entitled to draw on his agent in Spain for 27,500 dollars more than the flour cost in America, or than the sum for which he could have drawn had the flour been exported on account of a Spanish merchant. But the transaction would not end here: the 75,000 dollars would be vested in some species of Spanish or other European goods fit for the American market; and the freight, insurance, &c. on account of the return cargo, would perhaps increase its value to 100,000 dollars; so that in all, the American merchant might have imported commodities worth 52,500 dollars more than the flour originally sent to Spain." It is as impossible to deny that such a transaction as this is advantageous, as it is to deny that its advantage consists entirely in the excess of the value of the goods imported over the value of those exported. And it is equally clear, that America might have had the balance of payments in her favour, though such transactions as the above had been multiplied to any conceivable extent.

Instead, therefore, of endeavouring to fetter and restrict the trade with those countries from which we should otherwise import a greater value than we exported, we ought to give it every possible facility. Every man considers that market as the best in which he is able to obtain the highest price, or the greatest value in exchange for his goods; why then should he be excluded from it? Why compel a merchant to dispose of a cargo of muslin for L.10,000 rather than L.12,000? The wealth of a state is made up of the wealth of individuals; and we have yet to learn that any more effectual method of increasing individual wealth can be devised than to permit every person to make his purchases in the cheapest and his sales in the dearest market.

It would be difficult to estimate the mischief which absurd notions relative to the balance of trade have occasioned in almost every commercial country. In Great Britain they have been particularly injurious. It is principally to the prevalence of prejudices to which they have given rise, that the restrictions imposed on the trade between this country and France are to be ascribed. The great, and, indeed, the only argument insisted on by those who prevailed on the legislature to declare the trade with France a *nuisance* (*Prohibition Act, 1st William and Mary*), was founded on the fact, that the value of the imports from that kingdom considerably exceeded the value of the exports. The balance was termed a *tribute* paid by England to France; and it was sagaciously asked, what had we done that we should be obliged to pay so much money to our deadly enemy? It never occurred to these wise persons, that no merchant would import any commodity from France, unless it brought a higher price in this country than the commodity exported in its stead; and that the profit of the merchant, or, which is the same thing, the national gain, would depend on this excess of price. The reason assigned for prohibiting the trade, affords the best proof of its having been a lucrative one. There cannot, indeed, be a doubt, that an unrestricted freedom of intercourse between the two countries would be of the greatest service to both. The peculiarities in the soil and climate, and in the national character of the people, of Great Britain and France, enable the one to produce various species of raw and manufactured commodities at a cheaper rate than they can be produced by the other. If we were allowed freely to purchase and import under moderate duties, the silks, the wines, and the brandies of France, those things which we can supply cheaper than our ingenious neighbours would be taken in payment. An extensive market would thus be created for a vast variety of articles, and a natural and powerful stimulus would be applied to the industry of both countries. Nobody denies that the trade with America, Portugal, and the Baltic is advantageous; and if so, why is the trade with France to be considered as prejudicial? Supposing the trade between the two countries were perfectly free, does any one imagine that our merchants would export or import any commodity to or from France, provided they could either sell or buy it on better terms anywhere else? If the restrictions on the French trade be not really injurious, that is, if the trade with France be either a losing or a less advantageous one than that with other countries, we may rest assured that the throwing it open would not make a single individual engage in it.

---

[1] Pitkin on the *Commerce of the United States*, 2d ed. p. 280.

As the real price of commodities is always proportioned not only to the expense of their production, but also to the expense necessarily incurred in conveying them to the place where they are to be consumed, it is plain that a nation which prohibits trading with the countries in her vicinity must pay a higher price for her imported commodities, and be obliged to exact a higher price for those which she exports, than would be necessary were she able to procure the one or to dispose of the other in her immediate neighbourhood. If the same sort of wine could be bought at Bordeaux equally cheap as at Lisbon, the difference of freight would enable it to be sold cheaper in London. It is this principle, in fact, which renders the home trade peculiarly advantageous. The parties engaged in it live near each other, and consequently each obtains the commodity of which he stands in need at its cheapest rate, and without being obliged to pay any great additional sum on account of carriage. When, therefore, we restrict the trade with countries in our immediate vicinity, we act in the teeth of that very principle which is, in every other case, admitted to be advantageous. We compel such of our people as purchase foreign commodities, to buy them at a comparatively high price; while, by raising the price of the commodities we export, the market for them is injuriously contracted.

But the partisans of the exclusive or mercantile system will perhaps tell us, that they do not mean to contend that it is profitable to export a greater value than is imported, but that, by exporting an excess of raw and manufactured commodities, the balance of payments is rendered favourable, and that this balance (which they consider as representing the entire net profit made by the country on its transactions with foreigners) is always paid in *bullion*.

Favourable or unfavourable balance not always received or paid in bullion.

It will, however, be easy to show that this statement is altogether erroneous; that a balance, whether on the one side or the other, is seldom or never cancelled by means of bullion; and that this balance is not a measure, and has in fact nothing to do with the profit or loss attending foreign commercial transactions.

1. So long as the premium on foreign bills is less than the expense attending the transit of bullion from a country which has an unfavourable real exchange, no merchant ever thinks of subjecting himself to an unnecessary expense, by exporting bullion to pay a foreign debt. But though the premium on foreign bills had increased, so as to equal the cost of exporting the precious metals, for it cannot *exceed* this sum, it does not by any means follow that they would therefore be exported. That depends entirely on the fact, whether bullion be, at the time, the cheapest exportable commodity, or, in other words, whether a remittance of bullion be the most advantageous way in which a debt may be discharged. If a London merchant owe L.100 in Paris, he sets about finding out the cheapest method of paying it. On the supposition that the *real* exchange is two per cent. below par, and that the expense of remitting bullion, including the profit of the bullion merchant, is also two per cent., it will be indifferent to him whether he pay L.2 of premium for a bill of L.100 payable in Paris, or incur an expense of L.2, by remitting L.100 worth of bullion directly to that city. If the prices of cloth in Paris and London be such, that it would require L.103 to purchase and send as much cloth to Paris as would sell for L.100, he would undoubtedly prefer buying a bill or exporting bullion. But if, by incurring an expense of L.101, the debtor be able to send as much hardware to Paris as would sell for L.100, he would as certainly prefer paying his debt by an exportation of hardware. By doing so, he saves one per cent. more than if he bought a foreign bill or remitted bullion, and two per cent. more than if he exported cloth. If there had been any other commodity that might have been exported with more advantage, he would have used it in preference.

It is obvious, therefore, that the exportation of bullion is regulated by precisely the same principles which regulate the export and import of other commodities. It is exported when its exportation is most advantageous; that is, when it is less valuable at home and more valuable abroad than any other commodity; and it cannot be otherwise exported. The balance of payments might be a hundred millions against a country, without depriving it of a single ounce of bullion. No merchant would remit L.100 worth of gold or silver from England to discharge a debt in Paris, if he could invest L.98, L.99, or any smaller sum in any other species of merchandise which, exclusive of expenses, would sell in France for L.100. Those who deal in the precious metals are, we may depend upon it, as much under the influence of self-interest as those who deal in coffee or indigo. But who would attempt to discharge a foreign debt, by exporting coffee which cost L.100, if he could effect the same object by sending abroad indigo which cost only L.97? No person in his senses would export a hat to be sold for 20s. provided he could sell it at home for a guinea; nor would any person export an

Real Exchange.

ounce of bullion, if its value were not less in the exporting than in the importing country, or if there were any other commodity whatever that might be exported with greater advantage.

2. It is in vain to contend, that by permitting an unrestricted freedom of trade, one country might become indebted to another, which had no demand for any sort of ordinary merchandise, and which would only accept of cash or bullion in exchange for its exports. Such a case never did, and never will occur. A nation which is in want of money must also be in want of other things; for men only desire money because of its being the readiest means of increasing their command over the necessaries and enjoyments of life. The extreme variety, too, in the soil and climate, in the machinery, and in the skill and industry of the artisans belonging to different countries, must always occasion a considerable difference in the prices of their products. And until the cost of production be equalized, there must always be a foreign demand for those commodities which can be produced cheaper at home than abroad; and until the desire to accumulate be banished from the human breast, there must always be an inclination to send commodities from those countries where their exchangeable value is least, to where it is greatest.

3. In treating of the *nominal* exchange, we endeavoured to show, that it is impossible that any country should be able, for any length of time, to import or export a greater quantity of bullion than may be necessary to preserve the value of bullion in it in its proper relation to the bullion of other countries; or, which is the same thing, to have the *real* exchange either permanently favourable or unfavourable. But though this principle be strictly true in reference to its *aggregate* exchanges, it is incorrect when the state of its exchange with one country only is considered. Great Britain, for example, may constantly have the exchange in her favour with Portugal, provided she have it constantly, and to an equal extent, against her with the East Indies, or some other country. "She may," to use the words of Mr Ricardo, "be importing from the north the bullion which she is exporting to the south. She may be collecting it from countries where it is relatively abundant, for others where it is relatively scarce, or where, from some particular causes, it is in great demand. Spain, who is the great importer of bullion from America, can never have an unfavourable exchange with her colonies; and as she must distribute the bullion she receives among the different nations of the world, she can seldom have a favourable exchange with the countries with which she trades."[1]

It was by this principle that Lord King ingeniously, and, we think, successfully accounted for the nearly continued favourable exchange between this country and Hamburg, from 1770 to 1799. His Lordship showed that the importation of bullion from Hamburg and other countries was only equivalent to the quantity exported to the East Indies and consumed at home; that the demand corresponded to the supply; and that its value remained pretty stationary. The extraordinary influx of bullion into this country from the Continent at the era of the bank restriction in 1797, and the very favourable state of the exchange, were undoubtedly owing, in a very great degree, to the reduction in the issues of bank paper, and to the diminution of the gold currency caused by the hoarding of guineas, &c. In 1797 and 1798, above *five* millions of guineas were coined at the mint; and this extraordinary demand for gold is of itself abundantly sufficient to account for the very favourable exchange of that period, and for the length of time which it continued. But, at the same time that the demand for *gold* bullion for the mint was thus increased, the demand for *silver* bullion, for the purpose of exportation by the East India Company, had also been proportionally augmented. In 1795, the quantity exported on account of the Company, and of private persons, amounted to only 151,795 ounces.

In 1796 to............................290,777
1797...................................962,880
1798.................................3,565,691
1799.................................7,287,327

From this period the exportation of silver to the East Indies was very much reduced; and, in the years in which the exchange was most unfavourable, it had almost entirely ceased.

Instead, therefore, of the extraordinary importation of bullion from Hamburg in 1797 and 1798 affording, as Mr Bosanquet and others have supposed, a practical proof of the fallacy of the opinion of those who contend that it is impossible, for any length of time, to destroy the natural equality in the value of bullion in different countries, it is a striking example of its truth. Without this influx, bullion in this country could not have maintained its proper value, as compared with that of other countries. We imported it, because, owing to the reduction of the paper currency, and the increased exports by the East India Company, its value was rendered higher here than on the Continent; and, consequently, because the Continental merchants found it advantageous to send bullion to us, in the same manner as they would have sent corn, or any other commodity for which there happened to be an unusual demand in Great Britain. For, however favourable the *real* exchange between Hamburg and London might have been to the latter, we should not have imported a single ounce of bullion, had it not been, at the time, the most advantageous article with which Hamburg could discharge its debt to London.

4. In the absence of all other arguments, it would be sufficient to state, that it is physically impossible that the excess of exports over imports, as indicated by the custom-house returns, should be paid in bullion. Every country in the world, with the single exception of the United States, has its apparently favourable balance; and of course, if they really existed, they would have to be paid by an influx of bullion from the mines correspondent to their aggregate amount. It is certain, however, that the entire produce of the mines, though it were increased in a *tenfold* proportion, would be insufficient for this purpose! This of itself is decisive of the degree of credit which ought to be attached to the commonly received opinions on this subject.

5. In the last place, the profit on transactions with foreigners does not consist in the quantity of bullion imported from abroad, but in "the excess of the value of the imports over the value of the exports." If, in return for exported commodities worth *ten* or *twenty* millions, we import such as are worth *fifteen* or *thirty*, we shall gain 50 per cent. by the transaction, though the exports should consist entirely of bullion, and the imports of corn, sugar, coffee, &c. It is a ridiculous prejudice that would make us import bullion rather than any other commodity. But whatever the partisans of the exclusive system may say about its being a *preferable product*, a *marchandise par excellence*, we may be assured that it will never appear in

---

[1] See *Reply to Mr Bosanquet's Observations on the Report of the Bullion Committee*, p. 17; one of the best pamphlets that has ever been published on the subject of exchange.

the list of exports or imports, while there is any other commodity with which to carry on trade that will yield a larger profit.

Thus it appears that the excess of exports over imports, instead of being any proof of an advantageous commerce, is distinctly and completely the reverse ;—that a commercial country may, and almost always does, import commodities of greater value than it exports, without rendering itself indebted to foreigners ;—and that when a balance of debt has been contracted, that is, when the sum *payable to* foreigners for imported commodities is greater than the sum *receivable from* them for exported commodities, the balance will not be paid by sending bullion from the debtor to the creditor country, unless it be at the time the most profitable article of export.

We have, in the previous *section*, shown that fluctuations in the nominal exchange have no effect on foreign trade. When the currency is depreciated, the premium which an exporter derives from the sale of the bill drawn on his correspondent abroad, is barely equivalent to the increase in the price of the goods exported, occasioned by the depreciation. But when the premium on a foreign bill is not a consequence of a fall in the value of money, but of a deficiency in the supply of bills, there is no rise of prices, and under such circumstances the unfavourable exchange undoubtedly operates as a stimulus to exportation. As soon as the *real* exchange diverges from par, the mere inspection of a price current is no longer sufficient to regulate the operations of the merchant. If it be unfavourable, the premium which an exporter receives on the sale of bills must be included in the estimate of the profit he is likely to derive from the transaction. The greater that premium, the less will be the difference of prices necessary to make him export. And hence an unfavourable *real* exchange has exactly the same effect as a bounty on exportation equal to the premium on foreign bills.

But for the same reason that an unfavourable *real* exchange increases exportation, it proportionally diminishes importation. When the exchange is really unfavourable, the price of foreign commodities brought to our markets must be so much under their price at home, as not merely to afford, exclusive of expenses, the ordinary profit on their sale, but also to pay the premium which the importer must give for a foreign bill, if he remit one to his correspondent, or for the discount, added to the invoice price, if the latter draw upon him. A much less quantity of foreign goods will therefore suit our markets when the *real* exchange is unfavourable ; and fewer payments having to be made abroad, the competition for foreign bills is diminished, and the *real* exchange rendered proportionally favourable. In the same way, it is easy to see that a favourable *real* exchange must operate as *duty* on exportation, and as a *bounty* on importation.

It is thus that fluctuations in the *real* exchange have a necessary tendency to correct themselves. They can never, for any considerable period, *exceed* the expense of transmitting bullion from the debtor to the creditor country. But the exchange cannot continue permanently favourable or unfavourable to this extent. When favourable, it corrects itself by restricting exportation and facilitating importation ; and when unfavourable, it produces the same effect by giving an unusual stimulus to exportation, and by throwing obstacles in the way of importation. The true PAR forms the centre of these oscillations ; and though the thousand circumstances that daily and hourly affect the state of debt and credit, prevent the ordinary course of exchange from being almost ever precisely at par, its fluctuations, whether on the one side or the other, are confined within certain limits, and have a constant tendency to disappear.

Real Exchange.

The operations of the bill merchants have a tendency to lessen fluctuations in the *real* exchange.

The natural tendency which the exchange has to correct itself is powerfully assisted by the operations of the bill merchants.

England, for example, may owe an excess of debt to Amsterdam, yet, as the aggregate amount of the debts *due* by a commercial country, is generally balanced by the amount of those which it has to receive, the deficiency of bills on Amsterdam in London will most probably be countervailed by a proportional redundancy of them in some other quarter. Now, it is the business of the merchants who deal in bills, as of those who deal in bullion or any thing else, to buy them where they are cheap, and to sell them where they are dear. They therefore buy up the bills drawn by other countries on Amsterdam, and dispose of them in London ; and, by so doing, prevent any great fall in the price of bills on Amsterdam in those countries in which the supply exceeds the demand, and any great rise in Great Britain and those countries in which the supply happens to be deficient. In the trade between Italy and this country, the bills drawn on Great Britain amount almost invariably to a greater sum than those drawn on Italy. The bill merchants, however, by buying up the excess of the Italian bills on London, and selling them in France, Holland, and other countries indebted to England, prevent the *real* exchange from ever becoming very much depressed.

A large foreign expenditure has no permanent effect on the exchange.

An unusual deficiency in the supply of corn, or of any other article of prime necessity, the demand for which could not be immediately contracted, by causing a sudden augmentation of the imports from abroad, materially affects the state of debt and credit with foreign countries, and depresses the exchange. In time of war the balance of payments is liable to be still further deranged ; the amount of the bills drawn on a country carrying on foreign hostilities, being increased by the whole expense of its armaments abroad, and of subsidies to foreign powers. But neither the conjoined nor separate influence of both or either of these causes can exert any permanent influence over the exchange. A sudden increase in the accustomed supply of bills must, in the first instance, by glutting the market, occasion their selling at a discount ; but this effect can only be of temporary duration. The unusual facilities which are then afforded for the exportation of manufactured produce to the foreign market, and the difficulties which are thrown in the way of importation, never fail speedily to bring the *real* exchange to par.

In a period of profound peace we may, by exporting an excess of raw or manufactured produce, overload the foreign market, and occasion such a decline in the price of British goods abroad, as to render the imported less valuable than the exported commodities with which they have been purchased. But such a state of things speedily effects its own cure. The distress which it necessarily occasions leads to an immediate diminution of exports ; and the supply of British commodities in the foreign market being thus rendered more nearly commensurate with the demand, they of course sell for an adequate profit ; and the value of the imports again exceeds, as it always ought to do, the value of the exports. But whenever a country has a large foreign expenditure to sustain, its exports are proportionally augmented. Such an expenditure can only be discharged either by the government directly sending abroad an equivalent amount of commodities, or by means of bills of exchange drawn against produce exported by private individuals. Supposing the foreign expenditure of Great Britain during the late war to have amounted to ten or twenty millions a-year, it is evident we must have annually exported an equal amount of the produce of our land, capital, and labour, for which payment would be received, not, as in ordinary cases, by a corresponding importation of foreign commodities, but from the treasury at home. This is strictly true, even though it were admitted that the expenditure had, in the first instance, been entirely discharged by remittances of bullion; for the increased supply of bullion which was thus required could be obtained only by an equally increased exportation of other produce to the countries possessed of mines, or from which it could be advantageously imported. Foreign expenditure, by increasing exports precisely in proportion to its own amount, is incapable of exerting any permanent effect on the exchange.

Thus it appears that a *really* great excess of exports, instead of being any criterion of increasing wealth at home, is only a certain indication of great expenditure abroad. "When," says Mr Wheatley, "the exports exceed the imports, as they must do when there is a large foreign expenditure, the equivalents for the excess are received abroad in as full and ample a manner as if the produce which they purchased were actually imported and entered in the custom-house books, and afterwards sent to the seat of war for consumption. But from the circumstance of its not being inserted in the custom-house entries as value received against the produce exported for its payment, the latter is deemed to constitute a favourable balance, when it is in reality exported to liquidate a balance against us." (Wheatley *On the Theory of Money*, p. 219.)

Cause of the rise of the exchange in 1815 and 1816.

But however conclusive this reasoning may appear, it has nevertheless been contended, that it is at *variance with the fact;* and that the rise of the exchange in autumn 1814, and its restoration to par in 1816, when the restriction on cash payments at the bank was in full operation, is a practical and convincing proof that its previous depression had not been a consequence of the depreciation of the currency, but of the excessive supply of bills on London in the foreign market, occasioned by the expensive contest in which we were then engaged. According to our view of the matter, however, this fact leads to a precisely opposite conclusion. It is of no use to tell us that the exchange came to par while the restriction act was unrepealed. It was never contended that the fact of such law being in existence had any effect on the currency. The restriction was justly condemned, because it *enabled* the Bank of England to deluge the country with paper. If the bank had never abused that power,—if the proprietors had sacrificed their own individual interests to those of the public, and had constantly kept their paper on a level with bullion,—the restriction act, though unwise, would, as to consequences, have been the same as if it had never existed. The question is not, therefore, whether the exchange came to *par* while the restriction continued, but *whether it came to* PAR *while as many notes circulated as in the period of its greatest depression?* If this could be shown, and if it could also be shown that the effective demand for paper had not, at the same time, been proportionally increased, the argument would be conclusive; and we should be compelled to admit that a great comparative increase of paper money has no tendency to diminish its value, or to render the *nominal* exchange unfavourable!

But it would be worse than idle to set about proving by argument a fact so notorious as the prodigious diminution of bank paper in 1814, 1815, and 1816. In that period above 240 country banks stopped payment; and ninety-two commissions of bankruptcy were issued against these establishments; being at the rate of *one* commission against every *seven and a half* of the total number of banks existing in 1813! The Board of Agriculture estimated, that in the county of Lincoln alone above *three* millions of bank paper had been withdrawn from circulation; and the total diminution of the currency during the three years in question has seldom been estimated at less than from *sixteen* to *twenty* millions, though it probably amounted to a great deal more. Mr Horner, the accuracy and extent of whose information cannot be called in question, made the following statement on this subject, in his place in parliament:

"From inquiries he had made, and from the accounts on the table, he was convinced that *a greater and more sudden reduction of the circulating medium had never taken place in any country than had taken place since the peace in this country*, with the exception of those reductions that had taken place in France after the Mississippi scheme, and after the destruction of the assignats. The reduction of the currency had originated in the previous fall of the prices of agricultural produce. That fall had produced a destruction of country-bank paper, to an extent which would not have been thought possible, without more ruin than had actually ensued. The Bank of England had also restricted its issues. As appeared by the accounts recently presented, the average amount of its currency was not, during the last year, more than between L.25,000,000 and L.26,000,000; while two years ago it had been nearer L.29,000,000, and at one time even amounted to L.31,000,000. But without looking to the diminution of Bank of England paper, the reduction of the country paper was enough to account for the rise which had taken place in the exchange."

Here, then, is the cause of the exchange coming to par in 1815 and 1816. It had nothing to do with the cessation of hostilities, but was entirely a consequence of the increased value of our currency, caused by the sudden reduction of its quantity. Instead, therefore, of being at variance with the principles we have been endeavouring to elucidate, this fact affords the strongest confirmation of their perfect correctness. And having been sanctioned by the fullest experience, they may be considered as beyond the reach of cavil and dispute.

An objection of a different sort has been made, by a very able economist, to another part of the theory maintained in this *section*, of which it may here be proper to take some notice.

When the exchange becomes unfavourable, the premium, procured by the sale of the bill drawn on a foreign merchant to whom bullion has been consigned, is no greater than would be obtained by consigning to him coffee, tea, sugar, indigo, &c. of equal value. An unfavourable *real* exchange permits a merchant to export commodities which could not be exported were the *real* exchange at par, or favourable; but the advantage still remains of exporting those commodities in preference, whose price in the country from which they are exported, compared with their price in the country into which they are imported, is lowest. Suppose, for example, that the expense of transmitting bullion from this country to France is *three* per cent., that the *real* exchange is *four* per cent. against us, that the price of bullion is the *same* in both countries, and that coffee, exclusive of the expenses of carriage, is really worth *four* per cent. more in France than in England. In such a case, it is obvious, the exporter of bullion would realize only a profit of *one* per cent., while the exporters of coffee would realize, inclusive of the premium on the sale of the foreign bill, a profit of *seven* per cent. And hence the opinion maintained by Colonel Torrens (*Comparative Estimate*, &c.), that when the exchange becomes unfavourable, those commodities which contain the greatest value in the smallest bulk, or on which the expense of carriage is least, would be exported in preference, appears to rest on no good foundation. The prices of the commodities which nations trading together are in the habit of exporting and

eal
ange.

importing, are regulated not merely by the cost of their production, but also by the expense necessarily incurred in carrying them from where they are produced to where they are consumed. If Great Britain were in the constant habit of supplying France with corn and bullion, the average price of corn in France, because of the expense required to convey it from this country, would plainly be from ten to fifteen per cent. higher than in Britain; while, because of the comparative facility with which bullion might be transported from the one to the other, its value in Paris would not exceed its value in London more than one or two per cent. Now, supposing that when the prices of both corn and bullion in Great Britain and France are adjusted according to their natural proportions, the *real* exchange becomes unfavourable to us; it is clear, that this fall in the exchange gives no more advantage to the exporters of bullion than to those of corn. The rise in the price of foreign bills does not increase the expense attending the exportation of corn or bullion. It leaves the cost of producing and transporting these commodities exactly where it found it. During the depression of the exchange, the exporters of both articles derive a premium from the sale of the bills drawn on their foreign correspondents. But there can be no inducement to export bullion in preference to corn, unless the real price of bullion should increase more rapidly in France, or decline more rapidly in Great Britain, than the real price of corn.

Whatever, therefore, may be the depression of the exchange, the merchant invariably selects those commodities for exportation, which, exclusive of the premium, yield the greatest profit on their sale. If bullion be one of these commodities, it will of course be exported; if not, not. Bullion, however, of all commodities, is that of which the value approaches nearest to an equality in different countries, and hence it is the least likely to be exported during an unfavourable exchange. The demand for it is comparatively steady, and no great surplus quantity could be imported into one country without reducing its value, or exported from another without raising its value, so as to unfit it either for exportation or importation. A very small part only of an unfavourable balance is ever paid in bullion. The operations of the bullion merchant are chiefly confined to the distribution of the fresh supplies which are annually dug from the mines proportionally to the effective demand of different countries. Its price is too invariable, or, which is the same thing, its supply and demand are too constant, to admit of its ever becoming an important article in the trade between any two countries neither of which possesses mines.

In corroboration of this argument, we may mention that, according to the official statement laid on the table of the House of Commons, it appears that the expenses incurred by this country on account of the armies acting in Portugal and Spain during the following years, were as under:

In 1808	L.2,903,540
1809	2,450,956
1810	6,066,021
1811	8,906,700
1812 1813	31,767,794
1814	13,000,000

Of which, according to the same official statement, only the following sums were remitted in coin or bullion:—

In 1808	L.2,861,339
1809	461,926
1810	697,675
1811	748,053
1812 1813	3,284,435

Computed Exchange.

Of the sum of *five* millions voted to our allies in 1813 and 1814, not more than L.300,000 was sent in bullion, the rest being made up by the exportation of manufactured goods and military stores. (*Edinburgh Review*, vol. xxvi. p. 154.) The high market price of gold and silver in 1809, 1810, &c. could not, therefore, be owing to the purchases made by government, for they were not greater than the sums exported by the East India Company in 1798 and 1799, and in 1803, 1804, and 1805, when there was scarcely any perceptible rise in the price of bullion. The immense additions made to the paper currency of the country in 1809, 1810, &c. sunk its value compared with bullion, and was the true cause of the unfavourable *nominal* exchange of that period.

SECT. III.—COMPUTED EXCHANGE.

Computed exchange.

Having thus endeavoured to point out the manner in which variations in the comparative value of the currencies of nations trading together, and in the supply and demand for bills, separately affect the exchange, it now only remains to ascertain their combined effect. It is on this that the *computed* or actual course of exchange depends.

The computed exchange represents either the *sum* or the *difference* of the real and nominal exchange.

From what has been already stated, it must be obvious, that when the nominal and real exchange are both favourable or both unfavourable, the *computed* exchange will express their *sum;* and that when the one is favourable and the other unfavourable, it will express their *difference.*

When, for example, the currency of Great Britain is of the mint standard and purity, and the currency of France five per cent. degraded, the *nominal* exchange will be five per cent. in favour of this country. But the *real* exchange may, at the same time, be either favourable or unfavourable. If it be also favourable to the extent of one, two, three, &c. per cent. the computed exchange will be six, seven, eight, &c. per cent. in favour of this country. And, on the other hand, if it be unfavourable to the extent of one, two, three, &c. per cent. the *computed* exchange will be only four, three, two, &c. per cent. in our favour. When the *real* exchange is in favour of a particular country, provided the *nominal* exchange be equally against it, the *computed* exchange will be at par, and *vice versa.*

A comparison of the market with the mint price of bullion affords the best criterion by which to ascertain the state of the exchange at any particular period. When no restrictions are imposed on the trade in the precious metals, the excess of the market over the mint price of bullion affords a pretty accurate measure of the depreciation of the currency. If the market and mint price of bullion at Paris and London exactly corresponded, and if the value of bullion was the same in both countries, the *nominal* exchange would be at par; and whatever fluctuations the computed exchange might exhibit, must, in such a case, be traced to fluctuations in the *real* exchange, or, which is the same thing, to the supply and demand for bills. If, when the market price of bullion in Paris is equal to its mint price, it exceeds it ten per cent. in London, it is a proof that our currency is ten per cent. depreciated, and consequently the *nominal* exchange between Paris and London *must* be ten per cent. against the latter. Instead, however, of the *computed* or actual course of exchange being ten per cent. against London, it may be against it to a greater or less extent, or in its favour. It will be more against it provided the *real* exchange be also unfavourable,—it will be less against it provided the *real* exchange be in favour of London, though to a less extent than the adverse *nominal* exchange,—and it will be in fa-

Computed Exchange.

vour of London, should the favourable *real* exceed the unfavourable *nominal* exchange. Thus, if while British currency is ten per cent. depreciated, and French currency at par, the computed or actual course of exchange between Paris and London were twelve or fifteen per cent. against the latter, it would show that the *real* exchange was also against this country to the extent of two or three per cent. And if, on the other hand, the computed exchange was only five or six per cent. against London, it would show that the *real* exchange was four or five per cent. in its favour, and so on.

It has already been shown, that, in so far at least as the question of exchange is involved, the differences in the value of bullion in different countries are limited by the expense of its transit from one to another. And hence, by ascertaining whether a particular country exports or imports bullion to or from other countries, we are able to determine its comparative value in these countries. Suppose, for example, that the expense of conveying bullion from this country to France, including the profits of the bullion dealer, is two per cent.; it is clear, inasmuch as bullion is only exported *to find its level*, that whenever our merchants begin to export it to France, its value there must be two per cent. greater than in England; and, on the contrary, when they import bullion from France, it must be two per cent. more valuable here than in France. In judging of the exchange between any two countries, this circumstance must always be attended to. If no bullion be passing from the one to the other, we may conclude that its value is nearly the same in both; at all events, it is certain that the difference of its value is not greater than the expense of transit. On the supposition that the entire expense, including profit, &c. of conveying bullion from Rio Janeiro to London is five per cent., and that the London merchants are importing bullion, then it is clear, provided the real exchange be at par, and that the currency of both cities is at the mint standard, that the *nominal*, or, which in this case is the same thing, the *computed* exchange, will be five per cent. in favour of London. But if the currency of London be five per cent. depreciated, or, in other words, if the market price of bullion at London be five per cent. above its mint price, the *computed* exchange between it and Rio Janeiro, supposing the *real* exchange to continue at par, will obviously also be at par. It may therefore be laid down as a general rule, that as soon as bullion begins to pass from one country to another, *the expense of transit*, provided the mint and market price of bullion in the *exporting* country correspond, will indicate how much the value of bullion in it falls short of its value in the country into which it is imported; or, which is the same thing, will be equal to its unfavourable *nominal* exchange; and that, when the market exceeds the mint price of bullion in the *exporting* country, the expense of transit *added* to this excess will give the total comparative reduction of the value of the precious metals in that country. The converse of this takes place in the country *importing* bullion. When its currency is of the mint standard, the expense of transit measures the extent of its favourable *nominal* exchange; but when its currency is relatively redundant or degraded, the *difference* between the expense of transit and the excess of the market above the mint price of bullion, will measure the extent of the favourable or unfavourable *nominal* exchange. It will be favourable when the depreciation is less than the expense of transit, and unfavourable when it is greater.

From 1809 to 1815 inclusive, Great Britain continued to export gold and silver to the Continent. During this period, therefore, we must add the expenses attending its transit to the excess of the market over the mint price of bullion, in order to ascertain the true relative value of British currency, and the state of the *real* exchange. Mr Goldsmid stated to the bullion committee that, during the last five or six months of the year 1809, the expense of transporting gold to Holland and Hamburg, inclusive of freight, insurance, exporter's profits, &c. varied from four to seven per cent. But at the same time that the relative value of bullion in Britain was at five and a half (medium of four and seven) per cent. below its value in Hamburg, the market price of gold bullion exceeded its mint price to the extent or sixteen or twenty per cent. or eighteen per cent. on a medium; so that the currency of this country, as compared with the currency of Hamburg, which differed very little from its mint standard, was really depreciated to the extent of twenty-three and a half per cent. Now, as the *computed* or actual course of exchange varied, during the same period, from nineteen to twenty-one per cent. against London, it is clear that the *real* exchange could not be very different from par. Had the *computed* exchange been less unfavourable, it would have shown that the *real* exchange was in favour of London; had it been more unfavourable, it would, on the contrary, have shown that the *real* exchange was decidedly against London.

Provided an accurate account could be obtained of the expense attending the transit of bullion from this country to the Continent during the subsequent years of the war, we have no doubt it would be found, notwithstanding the extraordinary depression of the *nominal*, that the *real* exchange fluctuated very little from par; and that the exportation of gold and silver was a consequence, not of the balance of payments being against this country, but of its being advantageous to export bullion, because of its being less valuable here than on the Continent. No person will contend that, in 1809, 1810, &c. there was such a redundancy of gold or silver currency in this country as to sink the relative value of these metals. Any such supposition is altogether out of the question. During the period referred to, the precious metals were sent out of the country, because the depreciation of the paper currency exceeded the cost of the transit of bullion; and hence, because it was every body's interest to pay their debts in the depreciated currency, and to export that which was undepreciated to other countries where there was no law to prevent its passing at its full value as coin, or in which there was a greater demand for bullion. It is indisputably certain that, if our *paper currency* had been sufficiently reduced, the supply of gold in the kingdom in 1809, 1810, &c. compared with the demand which must, under such circumstances, have been experienced, was so very small, that, instead of exporting, we should have imported the precious metals from every country in the world.

It has been very generally supposed, that the extraordinary exportation of British goods to the Continent during the latter years of the war, was in a great measure owing to the depression of the exchange. But, in so far as this depression was occasioned by the redundancy or depreciation of the currency, it could have no such effect. It is impossible, indeed, to form any opinion as to the influence of fluctuations in the *computed* exchange on export and import trade, without previously ascertaining whether they are a consequence of fluctuations in the *real* or *nominal* exchange. It is only by an unfavourable *real* exchange that exportation is facilitated; and it may be favourable at the very moment that the *computed* exchange is decidedly unfavourable. "Suppose," to use an example given by Mr Blake, "the computed exchange between Hamburg and London to be one per cent. against this country, and that this arises from a *real* exchange which is favourable to the amount of four per cent. and a nominal exchange unfavourable to the extent of five per cent.; let the real price of bullion at Hamburg and London be precisely the same, and, consequently, the *nominal* prices different by the amount of the *nominal* exchange or five per cent; now if the expenses of freight, insurance, &c. on the transit of bullion from Hamburg are three per cent., it is evident that a profit would be derived from the import of that article, notwithstanding the *computed* exchange was one per cent. against us. In this case the merchant must give a premium of one per cent. for the foreign bill, to pay for the bullion: L.100 worth of bullion at Hamburg would therefore cost him L.101, and the charges of importation would increase the sum to L.104. Upon the subsequent sale, then, for L.105 of depreciated currency in the home market, he would derive from the transaction a profit of L.1. This sum is precisely the difference between the *real* exchange and the expenses of transit, that part of the *computed* exchange which depends on the *nominal* producing no effect; since whatever is lost by its unfavourable state is counterbalanced by a corresponding inequality of *nominal* prices." (*Observations*, &c. p. 91.) In the same manner it may be shown, that, though the *computed* be favourable, the *real* exchange may be unfavourable; and that, consequently, it might be really advantageous to export, when it was apparently advantageous to import. But it would be tedious to multiply instances, which, as the intelligent reader will readily conceive, may be infinitely varied, and which have been sufficiently explained in the foregoing sections.

The real cause of the extraordinary importation of British produce into the Continent in 1809, 1810, &c. notwithstanding the anticommercial system of Napoleon, is to be found, not in the state of the exchange; for, inasmuch as that was occasioned by a fall in the value of the currency, it could have no effect whatever either in increasing or diminishing exportation; but in the annihilation of the neutral trade, and our monopoly of the commerce of the world. The entire produce of the East and of the West was placed at our disposal. The continental nations could neither procure colonial produce nor raw cotton for the purposes of manufacturing, except directly from England. British merchandise was thus rendered almost indispensable; and to this our immense exportation, in spite of all prohibitions to the contrary, is to be ascribed. (See *Edinburgh Review*, No. lxiii. p. 50.)

Negotiation of Bills of Exchange.

In conducting the business of exchange, a direct remittance is not always preferred. When a merchant in London, for example, means to discharge a debt due by him in Paris, it is his business to ascertain not only the state of the direct exchange between London and Paris, and, consequently, the sum which he must pay in London for a bill on Paris equivalent to his debt, but also the state of the exchange between London and Hamburg, Hamburg and Paris, &c.; for it frequently happens, that it will be more advantageous for him to buy a bill on Hamburg, Amsterdam, or Lisbon, and to direct his agent to invest the proceeds in a bill on Paris, rather than remit directly to the latter. This is termed the ARBITRATION of exchange. An example or two will suffice to show the principle on which it is conducted.

Thus, if the exchange between London and Amsterdam be 35s. Flemish per pound sterling, and between Paris and Amsterdam 1s. 6d. Flemish per franc, then, in order to ascertain whether a direct or indirect remittance to Paris would be most advantageous, we must calculate what would be the value of the franc in English money if the remittance were made through Holland; for if it be less than that resulting from the direct exchange, it will obviously be the preferable mode of remitting. This is determined by stating, as 35s. Flem. (the Amsterdam currency in a pound sterling): 1s. 6d. Flem. (Amsterdam currency in a franc) : : L.1. : 10d. the proportional or *arbitrated* value of the franc. Hence if the English money or bill of exchange, to pay a debt in Paris, were remitted by Amsterdam, it would require 10d. to discharge a debt of a franc, or L.1 to discharge a debt of 24 francs: and, therefore, if the exchange between London and Paris were at twenty-four, it would be indifferent to the English merchant whether he remitted directly to Paris, or indirectly *via* Amsterdam; but if the exchange between London and Paris were *above* twenty-four, then a direct remittance would be preferable; while, if, on the other hand, the direct exchange were less than twenty-four, the indirect remittance ought as plainly to be preferred.

Negotiation of Bills of Exchange.

"Suppose," to borrow an example from Dr Kelly (*Universal Cambist*, vol. ii. p. 137), "the exchange of London and Lisbon to be at 68d. per milree, and that of Lisbon on Madrid 500 rees per dollar, the arbitrated price between London and Madrid is 34d. sterling per dollar; for as 1000 rees : 68d. : : 500 rees : 34d. But if the direct exchange of London on Madrid be 35d. sterling per dollar, then London, by remitting directly to Madrid, must pay 35d. for every dollar; whereas, by remitting through Lisbon, he will pay only 34d.; it is, therefore, the interest of London to remit indirectly to Madrid through Lisbon. On the other hand, if London draws directly on Madrid, he will receive 35d. sterling per dollar; whereas, by drawing indirectly through Lisbon, he would receive only 34d.; it is, therefore, the interest of London to draw directly on Madrid. Hence the following rules:

"1. Where the *certain price* is given, draw through the place which produces the lowest arbitrated price, and remit through that which produces the highest.

"2. Where the *uncertain price* is given, draw through that place which produces the highest arbitrated price, and remit through that which produces the lowest."

In COMPOUND ARBITRATION, or when more than *three* places are concerned, then, in order to find how much a remittance passing through them all will amount to in the last place, or, which is the same thing, to find the arbitrated price between the first and the last, we have only to repeat the different statements, in the same manner as in the foregoing examples.

Thus, if the exchange between London and Amsterdam be 35s. Flem. for L.1 sterling; between Amsterdam and Lisbon 42d. Flem. for 1 old crusade; and between Lisbon and Paris 480 rees for 3 francs, What is the arbitrated price between London and Paris?

In the first place, as 35s. Flem. : L.1 : : 42d. Flem. : 2s. sterling, = 1 old crusade.

Second, as 1 old crusade, or 400 rees : 2s. sterling : : 480 rees : 2s. $4\frac{4}{5}$d. sterling, = 3 francs.

Third, as 2s. $4\frac{4}{5}$. sterling : 3 francs : : L.1 sterling : 25 francs, the arbitrated price of the pound sterling between London and Paris.

This operation may be abridged as follows:

		L.1 sterling.
L.1 sterling	=	35s. Flemish.
$3\frac{1}{2}$ shillings Flem.	=	1 old crusade.
1 old crusade	=	400 rees.
480 rees	=	3 francs.

$$\text{Hence } \frac{35 \times 400 \times 3}{480 \times 3\frac{1}{2}} = \frac{4200}{168} = 25 \text{ francs.}$$

This abridged operation evidently consists in arranging the terms so that those which would form the divisors in continued statements in the *Rule of Three* are multiplied

Negotiation of Bills of Exchange.

together for a common divisor, and the other terms for a common dividend. Arithmetical books abound with examples of such operations.

The following account of the manner in which a very large transaction was actually conducted, by indirect remittances, will sufficiently illustrate the principles we have been endeavouring to explain.

In 1804 Spain was bound to pay to France a large subsidy; and, in order to do this, three distinct methods presented themselves;

1. To send dollars to Paris by land.
2. To remit bills of exchange directly to Paris.
3. To authorise Paris to draw directly on Spain.

The first of these methods was tried, but it was found too slow and expensive; and the second and third plans were considered likely to turn the exchange against Spain. The following method by the indirect or circular exchange was therefore adopted.

A merchant, or *banquier*, at Paris, was appointed to manage the operation, which he thus conducted: He chose London, Amsterdam, Hamburg, Cadiz, Madrid, and Paris, as the principal hinges on which the operation was to turn; and he engaged correspondents in each of these cities to support the circulation. Madrid and Cadiz were the places in Spain from whence remittances were to be made; and dollars were, of course, to be sent to where they bore the highest price, for which bills were to be procured on Paris, or on any other places that might be deemed more advantageous.

The principle being thus established, it only remained to regulate the extent of the operation, so as not to issue too much paper on Spain, and to give the circulation as much support as possible from real business. With this view London was chosen as a place to which the operation might be chiefly directed, as the price of dollars was then high in England, a circumstance which rendered the proportional exchange advantageous to Spain.

The business was commenced at Paris, where the negotiation of drafts issued on Hamburg and Amsterdam served to answer the immediate demands of the state; and orders were transmitted to these places to draw for the reimbursements on London, Madrid, or Cadiz, according as the course of exchange was most favourable. The proceedings were all conducted with judgment, and attended with complete success. At the commencement of the operation, the course of exchange of Cadiz on London was 36d.; but, by the plan adopted, Spain got 39¼d. or above eight per cent. by the remittance of dollars to London, and considerable advantages were also gained by the circulation of bills through the several places on the Continent.[1]

Usance days of grace.

Bills of exchange are made payable at *sight*;—at a certain specified time *after sight*, or *after date*;—or at *usance*, which is the usual term allowed by the custom or law of the place where the bill is payable. Generally, however, a few days are allowed for payment beyond the term when the bill becomes due, which are denominated *days of grace*, and which vary in different countries. In Great Britain and Ireland *three* days of grace are allowed for all bills except those payable at sight, which must be paid as soon as presented.

The following is a statement of the *usance* and *days of grace* for bills drawn by London on some of the principal commercial cities:

[*m*|*d*. *m*|*s*. *d*|*d*. *d*|*s*. *d*|*a*. respectively denote *months after date*, *months after sight*, *days after date*, *days after sight*, *days after acceptance*.]

London on	Usance.	Days of Grace.	London on	Usance.	Days of Grace.
Amsterdam	1 m|d.	6	Gibraltar...	2 m|s.	14
Rotterdam.	1 m|d.	6	Leghorn....	3 m|d.	0

In the dating of bills the new style is now used in every country in Europe with the exception of Russia.

In London, bills of exchange are bought and sold by brokers, who go round to the principal merchants, and discover whether they are buyers or sellers of bills. A few of the brokers of most influence, after ascertaining the state of the supply and demand for bills, suggest a price at which the greater part of the transactions of the day are settled, with such deviations as particular bills, from their being in very high or low credit, may be subject to. The price fixed by the brokers is that which is published in Wettenhall's list; but it is stated by Mr Goldsmid, that the first houses generally negotiate their bills on a half, one, one and a half, and two per cent. better terms than those quoted. In London and other great commercial cities, a class of middlemen speculate largely on the rise and fall of the exchange, buying bills when they expect a rise, and selling them when a fall is anticipated.

History and Advantages of Bills of Exchange.

It is not easy to discover the precise era when bills of exchange were first employed to transfer and adjust the mutual claims and obligations of merchants. Their invention has been ascribed to the Arabians and the Jews of the middle ages; but it seems certain that bills were in use in remote antiquity. Isocrates states that a stranger who brought some cargoes of corn to Athens, furnished a merchant of the name of Stratocles with an order or bill of exchange, on a town on the Pontus Euxinus, where money was owing to him; and, because the person who had drawn the bill had no *fixed domicile*, Stratocles was to have recourse on a merchant in Athens, in the event of its being protested. The merchant, says Isocrates, who procured this order found it extremely advantageous, inasmuch as it enabled him to avoid risking his fortune on seas covered with pirates and the hostile squadrons of the Lacedæmonians. (De Pauw, *Recherches sur les Grècs*, i. 258.)

There is also unquestionable evidence to show that the method of transferring and cancelling the debts of parties

[2] In France no days of grace are allowed on bills payable *à vue*.

[3] In Austria, bills payable at sight, or on demand, or at less than seven days after sight or date, are not allowed any days of grace.

History of Bills of Exchange.

residing at a distance, by means of letters of credit, or, which is in effect the same thing, by means of bills of exchange, was not unknown to the Romans. Cicero, in one of his epistles to Atticus (*Epist. ad Atticum*, xii. 24), inquires whether his son must carry cash to defray the expense of his studies along with him to Athens, or whether he might not save this trouble and expense *by obtaining an assignment for an equivalent sum from a creditor in Rome on his debtor there.* It is evident, from a subsequent epistle of Cicero's, that the latter method had been preferred, and that the transference of the money had in consequence been rendered unnecessary. (*Epist. ad Atticum*, xii. 27.)[1]

Mr Macpherson states (*Annals of Commerce*, i. p. 405), that the first mention of bills of exchange in modern history occurs in 1255. The pope having quarrelled with Manfred, king of Sicily, engaged, on Henry III. of England agreeing to indemnify him for the expense, to depose Manfred, and raise his second son Edmund to the Sicilian throne. The enterprise misgave. But the merchants of Sienna and Florence who originally advanced the money to carry it into effect, or rather to gratify the pope's rapacity, were paid by bills of exchange drawn on the *Prelates* of England, who, although they protested they knew nothing at all about the transaction, were nevertheless compelled, under pain of excommunication, to pay the bills and *interest!*

Capmany, in his *Memoirs* respecting the Commerce, &c. of Barcelona, gives a copy of an ordonnance of the magistracy, dated in 1394, enacting that bills should be accepted within twenty-four hours after their presentation;—a sufficient proof that they were in general use in the beginning of the fourteenth century.

But whatever be the era of the introduction of bills of exchange, very few inventions have redounded more to the general advantage. Without this simple and ingenious contrivance, commerce could not have made any considerable progress. Had there been no means of settling and adjusting the mutual claims of debtors and creditors otherwise than by the intervention of metallic money (for bank paper is only another species of bills of exchange), a very great proportion,—many hundreds of millions,—of that capital which is now setting productive labour in motion in every quarter of the globe, and ministering to the wants and the enjoyments of mankind, must have been devoted to the expediting those exchanges which are much better accomplished by the agency of a few quires of paper. Instead of a perpetual importation and exportation of gold and silver, necessarily attended by an immensity of trouble and expense, a few bills of exchange, possessing little or no intrinsic worth, and which may be transferred with the utmost facility, suffice to adjust the most extensive and complicated transactions. But the mere setting free of an immense productive power, engaged in a comparatively disadvantageous employment, is only one of the many benefits we owe to the use of bills of exchange. By cheapening the instruments by which commerce is carried on, they have materially reduced the prices of most commodities; and have, in consequence, increased the command of all classes over the necessaries and luxuries of life, and accelerated the progress of civilization, by occasioning a much more extensive intercourse and intimate connection between different and independent countries, than could otherwise have taken place.

In a political point of view their effects have been equally salutary. They enable every individual imperceptibly to transfer his fortune to other countries, and to preserve it safe alike from the rapacity of his own government and the hostile attacks of others. The security of property has, in consequence, been prodigiously augmented. And though we should concede to the satirist that paper credit has "lent corruption lighter wings to fly,"[2] it is easy to show that it has powerfully contributed to render subjects less dependent on the policy, and less liable to be injuriously affected by injudicious measures on the part of their rulers. In countries in a low stage of civilization, the inhabitants endeavour, by burying all the gold and silver they can collect, to preserve a part of their property from the despots by whom they are alternately plundered and oppressed. This was universally the case in the middle ages; and in Turkey, India, Persia, and other eastern countries, the practice is still carried on to a very great extent. Some economists have endeavoured to account for the long-continued importation and high value of the precious metals in India, by the loss which necessarily attends the practice of hoarding; and undoubtedly this locking up of capital is one of the main causes of the extreme poverty of these countries. But the security afforded by bills of exchange is infinitely greater than any derived from the barbarous expedient of trusting property to the bosom of the earth. "Pregnant with thousands flits the *scrap* unseen," and in a moment places the largest fortune beyond the reach of danger! Mr Harris was, therefore, right in saying, "that the introduction of bills of exchange was the greatest security to merchants, both as to their persons and effects, and consequently the greatest encouragement to commerce, and the greatest blow to despotism, of any thing that ever was invented." (Harris *on Coins*, part i. p. 108.)

Previously to the peace of Paris in 1763, Amsterdam, because of its commerce, the wealth and punctuality of its merchants, and their intimate connection with all the other great trading cities of the world, was the chief place where the accounts of the different commercial countries were balanced and adjusted. But the entire loss of foreign trade, and the other vexations to which Holland was subjected during the ascendancy of the French, nearly divested Amsterdam of all share in this business. London has now become the trading metropolis of Europe, and of the world. The vast extent of its commercial dealings has necessarily rendered it the great mart for bills of exchange. Its bill merchants, a class of men remarkable for their shrewdness, and generally possessed of large capitals, assist in trimming and adjusting the balance of debt and credit between the most remote countries. They buy up bills where they are cheap, and sell them where they are dear; and, by the extent of their correspondence and the magnitude of their transactions, give a steadiness to the exchange, which it could not otherwise attain.

---

[1] "De Cicerone, ut scribis, ita faciam: ipsi permittam de tempore: nummorum quantum opus erit ut *permutetur* tu videbis." In his notes on a parallel passage, Grævius remarks, *Permutatio* est quod nunc barbare *cambium* dicitur. (*Epist. ad Atticum*, xi. 24.)

[2] Blest paper credit! last and best supply!
That lends corruption lighter wings to fly!
Gold imp'd by thee can compass hardest things,
Can pocket states, can fetch or carry kings;
A single leaf shall waft an army o'er,
Or ship of senates, to some distant shore;
A leaf, like Sibyll's, scatter to and fro
Our fates and fortunes, as the wind shall blow;
Pregnant with thousands flits the scrap unseen,
And silent sells a king, or buys a queen.—POPE.

Laws and Customs Respecting Bills and Notes.

Law respecting bills, &c.

A bill of exchange may be defined to be an open letter of request or order from one person, the *drawer*, to another person, the *drawee*, who is thereby desired to pay a sum of money, therein specified, to a third person, the *payee*. When the *drawee* obeys the request or order, by subscribing the document, he becomes *acceptor*. If the contrary do not appear on the face of the bill, it is presumed that the *drawee* has funds of the *drawer's* in his hands to the amount of the bill, and that the drawer is indebted to the *payee* to that extent. The bill thus operates as a transfer or mercantile assignment to the payee, of the drawee's debt to the drawer. But a bill may also be drawn payable to the *drawer* or his order, in which case, when accepted, the document is not an assignment, but merely the acknowledgment or constitution of a debt. This is also accomplishable by *promissory note*, which is a promise by one person, the *maker* (Scoticé *granter*), to pay a sum to another person, the *payee* (Scoticé *grantee*). The bill and the promissory note have now equally the privilege of being *assignable* or *transferable* from one person to another by indorsement, that is, by the *payee* subscribing his name on the back of the document. In this case the *payee* becomes an *indorser*, and the person in whose favour the indorsement is made is called the *indorsee*, who may again indorse to another; and in this manner the bill or note may pass from hand to hand without limitation. Each indorsation may be made *in full* or *in blank;* in full, by filling up the name and description of the party in whose favour it is made, which is attended with several advantages if the document should be lost or stolen; in blank, by merely subscribing the indorser's name, which is equivalent to making it payable to the *bearer*. All the indorsements, or any one of them, may also be *qualified* by the words *without recourse;* and when this is done, neither the indorsee nor any subsequent *holder* of the bill or note can have recourse on the indorser who thus qualifies his indorsation. If none of the indorsations be so qualified, the *last holder* for value, and *in bona fide*, has all the prior indorsers and other parties to the bill or note bound to him jointly and severally. He may select any one of them, or proceed against them all at the same time; and if all were to become bankrupt, he could claim on the estate of each for the whole debt, and be entitled to receive dividends from all the estates until he obtained *full payment*, but which he must not exceed. An indorser may also qualify his indorsation by the condition that his indorsee shall not have the power of making an indorsement from himself.

From the negotiability thus conferred upon them, bills have been compared to bags of money; but it should be remembered that, in the former case, we transfer only *a right*, in the latter the *property itself*. The comparison is best supported in those transferences which are made without recourse, since, in those instances, the bill passes from hand to hand without any alteration in the rights and duties of those interested in it, and without any one acquiring an additional security. In the simplest case, however, the rights arising on a bill may be preserved or lost by the conduct of the holder; and where there has been even one unqualified indorsation, the duties of the holder are of a delicate and important nature. But these will be more readily understood after we have pointed out the requisites of a bill.

The general requisites of a bill are, that it must be payable at all events; that it must be for payment of money only; and that the money must not be payable from any particular fund. Of the more special requisites, the *first* is, that any bill or note drawn or made in Great Britain (though dated abroad[1]) or in its colonies, is, that it be written on paper *stamped* according to the law of the mother country or colony, as it happens to be drawn in the one or the other. The stamp-duty varies according to the sum in the bill, and the extension of the term of payment: but for these particulars, and the mode of complying with the provisions of the law, reference should be made to the statutes in force at the time. The present regulating statute is that of 55 Geo. III. c. 184, both as to *inland* bills and notes, and bills of exchange drawn here *on* foreign countries. As to bills truly drawn in foreign states, not colonies of Great Britain, on traders in this country, our law takes no cognizance of them as to whether they are or are not stamped; but *promissory notes* made *out* of Britain are declared *not* to be negotiable or payable unless stamped agreeably to our laws. Bills drawn at home must also be written on the stamp appropriated for bills. If on a stamp of another denomination, though of equal or superior value, they are invalid if not got re-stamped, which they may be for payment of the duty and a penalty of 40s. when carried to the stamp-office before they are due, but when after due, the penalty is L.10. If written on a stamp below the proper value, a penalty is incurred of L.50, and the bills, besides, are *null* (Bell's *Com. on Bankrupt Law*, vol. ii. p. 249); but it has been found with us in England, that if a bill be *not* properly stamped, a neglect to present for acceptance or payment will not relieve parties who are *otherwise* liable in the *original debt* in respect of which the bill was granted. The relief in this case is granted by a court of equity, but this relief is not extended to remote indorsers not responsible for the original debt. Relief, however, is given when a party has bound himself to grant a valid note or bill, but gives one by mistake or design on a defective stamp. Negotiable bills under L.5 must, by 37 Geo. III. c. 32, be payable within twenty-one days, and bear the name of the *place* where they are made, without which also *checks* on bankers are liable to stamp-duty. Penalties are likewise imposed on the post-dating of such *checks*, or of bills, for the purpose of reducing the duty by apparently shortening the term of payment; and there are provisions in those laws respecting bills drawn in sets or otherwise, with which every trader should make himself acquainted. This, however, it is very difficult to do in all its bearings, since the penalties and provisions of the prior statutes are retained in every subsequent one, except as therein specially altered. This is one great evil in our fiscal regulations. Where the law cannot be known, transactions are rendered uncertain, property insecure, and litigation is increased to a mischievous extent. But the worst evil is, that this state of the law increases in a prodigious degree the influence of the crown, by the power over traders which is thus placed in the hands of solicitors of stamps, excise, customs, and other crown officers.

The other requisites of a bill are, *2dly*, That it should bear the name of the place at which it is made or drawn; and if the street and number of the house be added, it is

---

Laws of Bills of Exchange.

easier to give and receive the notices that may be necessary, in proper time. 3*dly*, The *date* should be distinctly marked, and, if *written* at length, a higher protection would be afforded against accidental or intentional alterations and vitiations. If a bill have no date, the date of issuing will be held as the date of the bill. 4*thly*, The time of payment should be clearly expressed, and a *time certain* is necessary to make the document *negotiable*; that is to say, the payment must not depend on an event that may never happen, such as the *marriage of a person*, though it may on the *death*. 5*thly*, The *place* at which a bill is made payable should also, for the sake of safe negotiation, be distinctly stated; because at that place *presentment* must be made both for acceptance and payment. If no place be mentioned, the place of doing business, if the acceptor have one, or otherwise his dwelling-house, becomes the place of presentment. 6*thly*, The sum payable should be clearly written in the body of the bill, and the superscription of the sum in figures will aid an omission in the body. This sum must in all cases be above 20s.; and if payable more than twenty-one days after date, it must exceed L.5. 7*thly*, It should contain an order or request to pay. 8*thly*, Of bills drawn in parts or sets, each part or copy should mention the number of copies used, and be made payable on condition that none of the others has been paid. The *forgery* of an indorsement on one of the parts passes no interest even to a *bona fide* holder, and will not prevent the payee from recovering on the other part. 9*thly*, Every bill should specify distinctly *to whom* the contents are to be paid; but a *bona fide* holder, or his executor, may fill up a blank, if one be left, for the name of the payee, and recover payment. (Chitty, 82; Bell, vol. ii. p. 251, &c.) 10*thly*, If it be intended that a bill is to be negotiable, it should contain the operative words of transfer "to order;" although, if the original intention be clear, these words may be inserted without a fresh stamp. (Chitty, 86.) 11*thly*, It is advisable in all cases to insert *value received*; since, without these words, the holder of an *inland* bill for upwards of L.20 could not, in England, recover interest and damages against the drawer and indorser in default of acceptance or payment. Bills bearing for value received, and payable *after date*, seem also to possess advantages when lost, under the statutes 9 and 10 W. III. c. 17; but equity would probably extend these to indorsements; and 3 and 4 Anne, c. 9, it is thought, extends the same to notes. (Chitty, p. 196.) 12*thly*, As to foreign bills, the drawee should attend to whether they are to be paid *with* or *without further advice*; since the propriety of his accepting or paying will, in the one case, depend on his having received advice. The more carefully all these requisites are attended to, the greater is the security of all concerned against accidents and litigation. But traders, we fear, have too generally a prejudice in favour of that brevity which approaches to looseness of expression, and against that precision which alone can keep them out of difficulties.

Ge l expl a- tor les and ges.

When a bill, check, or note, is payable *on demand*, or when *no time of payment is expressed*, it should be presented within a reasonable time after receipt, and is payable *on presentment*, without the allowance of any days of grace. It is yet *unsettled* (Chitty, 344, *et seq.*) whether bills drawn *at sight* are entitled to days of grace, though the weight of authority is rather in favour of them. If drawn at one or more days after sight, the days of grace must be allowed. The day on which a bill is dated is not reckoned one; but all bills having days of grace, become due, and must be presented and protested, *on the third day*, and if that day be a Sunday or holiday, on *the second*. The rule for giving notice of non-acceptance or non-payment is different, since, if the day on which it should have been given be a day of rest, by the religion of the party, such as the Jews' Sabbath, the notices will be good if given on the next day. Calendar months are always understood with respect to bills; and if dated on the 29th, 30th, or 31st of January, payable *one month* after date, they will fall due on the *last day* of February, from which the days of grace are to be calculated. Presentments of bills should be made within business hours. These are generally considered to be in London from nine morning to six evening, but a protest has been held good against an ordinary trader when made at eight. This would not have been good in the case of bankers, whose hours (from nine to five in London) must be attended to. In Edinburgh, bankers' hours are from ten to three; traders from ten to three and from six to eight; but there are no Scotch decisions holding these as the only business hours. A verbal notice of the dishonour of an *inland* bill is good; but as such notice is always matter of parole evidence, it is better in every case to give notice in writing, and the regular mode of doing so is by post. Such notice, if put into the general post-office, or an authorized receiving-house, is good though it miscarry, provided the letter be regularly booked, and reasonable proof be made of its having been put into the post-office. If given only to a bellman in the street, it would not in such a case be good. When there is no post, the ordinary mode of conveyance, such as the *first* ship or carrier, is sufficient. As to *foreign bills*, notices of dishonour, with the respective protests, must be dispatched by post on the day when the bills become due, or on which the acceptance was refused, if any post or ordinary conveyance set out that day, and if not, by the next earliest conveyance. (Chitty, 291.) As to *inland* bills, notice should be made by the first post after the expiry of a day, when the parties reside at a distance; if in the same town it is enough if the notice be made so as to be received within business hours of the following day, and this may be done by the twopenny or penny post, if receivable within the time mentioned. When a holder deposits his bill at his banker's, the number of persons entitled to notice is increased by one; and each party in succession is entitled to *twenty-four hours* for giving notice (6 East. 3 Bell, 263.) Such notice, as to inland bills, is necessary in England for preserving recourse as to the principal sum only. If protest be made and notice given within fourteen days, the recourse is preserved as to *interest*, damages, and expenses. In Scotland a protest is necessary in every case, and there is no distinction made as to the mode of recourse between principal and interest; but intimation to the drawer within *fourteen* days preserves recourse for the whole (Bell, vol. ii. p. 265); and it has been decided, that notice of an indorser may be good even after the fourteen days, if there has been no unnecessary delay. (*Fac. Col.* 2d June 1812.) But this applies only to *inland* bills, and a bill drawn from Scotland upon England is in Scotland held to be foreign. (Bell, vol. ii. p. 265.) Every bill should be presented for payment on the day upon which it falls due, unless that be rendered impossible by some unforeseen and *inevitable* accident, such as shipwreck, or sudden illness, or death. To preserve recourse, the accident, and the presentment of the bill as soon as possible afterwards, must be intimated without delay, and, if denied, proved by the party who seeks recourse. The same doctrine will hold as to presentments for non-acceptance and notices of dishonour. But the loss or destruction of a bill is no excuse for not demanding payment and protesting; the protest in that case being made upon a copy or statement of the bill, if the party who has right to hold the bill has it in his power to make such a statement. If the destruction of the bill can be proved, action will be sus-

Business hours.

Rules of giving notices.

Effect of inevitable accident.

How to act when bill lost.

tained in a court of law; if not, the redress is got upon giving an indemnity in a court of equity; but as equity will not interfere where law can, it is of importance in such a case, and indeed in all cases of difficulty, to resort at once to the best professional advice. Inconsiderate attempts to remedy neglects, or cure what is defective, generally make the case worse, and often implicate character.

Effect of usury.

Cases of great hardship and difficulty frequently arose on bills granted partly for *usurious* consideration. A mighty benefit, however, has now been conferred by the statute 58 Geo. III. c. 93, which enacts, "That *no bill* of exchange or promissory note that shall be drawn or made after the passing of this act shall, though it may have been given for a usurious consideration, or upon a usurious contract, *be void* in *the hands of an indorsee for valuable consideration*, unless such an indorsee had, at the time of discounting or paying such consideration for the same, *actual notice* that such bill, &c. had been originally given for a usurious consideration, or upon a usurious contract."

Effect of gaming.

It is much to be regretted that the same protection was not extended by this statute to the *innocent holder* of a bill granted for a game debt. Such bills are still void in the hands of a *bona fide* indorsee. In Scotland it has been decided otherwise. (25th January 1740, Nielson; Bell, vol. ii. p. 210.) The rage for legislation has not yet extended itself to lawyers, who, as a body, can hardly be expected to display an anxiety to remedy defects which add to their emoluments and consequence. How much of the learning of this profession is wasted on niceties and difficulties that would readily yield to the spell of an act of parliament! To the law, however, we owe this sound maxim, that "unless it has been so expressly declared by the legislature, as it formerly was in the case of usury, and still is as to bills for *game* debts, illegality of consideration will be no defence in an action at the suit of a *bona fide* holder, without notice of the illegality, unless he obtained the bill after it became due." (Chitty, 105.)

Effect of forgery.

Thus *forgery* does not vitiate a bill. The forged document is good to and against all parties but those whose names are forged. Against one whose name is forged, it is true, it will neither support an action nor ground a claim; "yet if he have given credit to acceptances or indorsations as binding on him, forged by the same hand, he will be liable." (3 Esp. N. P. 60; 2 Bell, 250.) Subsequent approbation also does away an objection on the head of forgery or fraud, and generally all sorts of objections otherwise competent.

Effect of vitiation.

This doctrine holds as to vitiations when the stamp laws are not concerned; but without the consent of parties all vitiations or alterations of bills in material parts are fatal. (2 Bell, 252.)

Acceptance by procuration.

A clerk or servant may accept a bill for his master if authorized so to do; and authority will be inferred from a sanctioned practice. The law on this point is dangerous, and would require legislative revision. If the servant or agent do not explain the character in which he acts, but subscribes his own name simply, he will bind himself, not his employer.

Conditional acceptance.

An acceptor may enlarge the term of payment, or accept for a part, or under any other condition not expressed in the bill; but in that case it is optional in the holder to take the acceptance as thus offered, or to proceed as if no such offer had been made; if rejected, the protest should bear the condition, and the rejection of it; it should also be kept in view, that a *holder* who accepts of a limited or conditional acceptance, liberates the drawer and prior indorser, unless he have their consent.

Indorsements.

Blank indorsements are held to be of the date of the bill, until the contrary is proved. Indorsements after the term of payment, though for value, do not protect the indorsees like indorsements before maturity; very slight evidence is admitted as proof of knowledge of dishonour, and the holder in that case becomes liable to all exceptions which can be stated against the right of his immediate indorser, or the person who held the bill when it became due. When acceptance is refused, and the bill returned with protest, action may be raised immediately against the drawer, though the regular time of payment is not arrived. His debt, in such a case, is considered as contracted the moment the bill was drawn; if the date of the bill be prior to that of a commission of bankrupt, the debt, in such a case, may be claimed upon. As to current bills and contingent claims, the case is unfortunately different; in these respects England might derive great help from the law of Scotland.

The *drawee*, who, having funds, refuses to accept, is responsible for the consequences to the *drawer*, and may also be sued for payment by the payee or holder, the presentment and protesting of the bill for non-acceptance operating as an intimated assignment and complete transfer of the debt *to the holder*, who in Scotland is preferred to any subsequent arrester. The *drawee* who has no funds is not bound to accept; but, after protest for non-acceptance, he may accept supra-protest, for the *honour* of the drawer and indorsers, or either of them. A *third party* may thus accept for *honour* supra-protest; and whoever does so, if he give immediate notice, and send off the protest, may have immediate recourse on the party or parties for whose honour he has interfered.

It is the duty of a *payee*, when directed by the drawer, and of every one who is merely an agent for the owner, though acting gratuitously, to present a bill for acceptance. The time thought reasonable for this purpose is twenty-four hours, or at least within business hours of the day following that on which the bill was received. It is prudent in all holders of a bill to present for acceptance within this period; and *in all cases* where a presentment is made, and acceptance refused, notice should be given to all against whom it is meant to preserve recourse. A draught may be left twenty-four hours with the drawee, if no post go out in the mean time; but if he intimate within that time that he will not accept, or ask *more time* to consider, *notice should be given.* (Chitty, 288, 289.) A verbal acceptance, if it can be proved, or one by a separate writing, binds the drawee; but in Scotland none but a written acceptance on the bill will authorize the usual summary diligence. (Chitty, 217–270; 2 Bell, 69–240.) If the drawee had no funds, notice to the drawer is not necessary; but as the not having funds is a matter of fact to be proved, it is safer in this, and indeed in all other cases, to give the usual and regular notice. When a bill is drawn at some certain time *after sight*, presentment is *necessary* to fix the term of payment. Respecting bills of this description, both foreign and inland, the general rule is, that *due diligence must be used.* Foreign bills, so drawn, may be put into the circulation without acceptance as long as the convenience of the successive holders requires; and it has been found not to be *laches* (in Scotland *mora*, or undue delay) to keep a bill (at three days' sight) out in the circulation for twelve months; but if, instead of circulating, a holder were to lock it up, this would be *laches.* An unacceptable inland bill may also be put into circulation; and any holder, who does not circulate it, has a reasonable time, such as the fourth day respecting a bill drawn within twenty miles of London, for presenting it there for acceptance. Dispatch and attention, however, are always advisable. It is said that when a bill has been already protested for non-acceptance, and due notice thereof given, it is not necessary to protest or to give notice on account of non-payment, but it is usual to do so, and the safer practice. The same rules and the same time should be observed as to non-payment, that are observed as to protest and notice, in the case of non-acceptance. When inland bills are made payable on a day named and fixed in the bills, it is common to delay presenting them for acceptance, until they can also be presented for payment, and then, if necessary, to protest for both; but it is better to make a presentment for acceptance as soon as it can be done in the ordinary course of business. It has already been stated, that notice either of non-acceptance when a presentment has been made, or for non-payment, *must* be given *to all the parties* to whom the *holder* intends to resort for payment. Bankruptcy is no excuse for neglecting any step in the negotiation of a bill. If a party be bankrupt, notice of recourse should be given to him and his assignees; if *dead,* to his executor or administrator; if abroad, the notice should be left at his place of residence, if he have one, and a demand of acceptance or payment (when that is necessary) should be made of his wife or servant. Notice should also be made to one who merely guarantees payment; and a person who subscribes a bill not addressed to him is held to be a collateral security. If notice be made to one indorser, he may give notice to prior indorsers, or to the drawer; and if done timeously, it will be available to the holder; but notice by a party, not party to the bill, nor agent for a party, will not be available.

Laws of Bills of Exchange.

Accommodation paper.

Accommodation bills are subject to the same rules as other paper, except among those who agree to lend their names or credit. Among them the rule is, that he for whose use the money is to be raised shall provide for the bill; but as all the others have an action of relief when forced to pay, they are entitled to notice. In Scotland this has been extended to the drawer when he is not the party for whom the credit was intended. With respect to cross paper, it is held that mutual accommodations exchanged are good considerations for each other; that in case of bankruptcy, a dividend from any one estate is to be held as payment of all that can be demanded in respect of that debt; and that there can be no double ranking of the same debt. But questions often arise in such cases, which require the utmost professional skill to comprehend and decide. In a short digest of this nature it is impossible to enter into the niceties of legal questions; and we can only observe generally, that parties should never act in cases of difficulty, without taking the best professional assistance.

Cross paper.

The *law* respecting bills of exchange is more consonant to reason than almost any other branch of our law, since, where it is silent, recourse is had to the custom of merchants.

The best authorities respecting the law of bills are the treatises of Chitty and of Bayley as to English law, and Mr Bell's *Commentaries on Mercantile Jurisprudence* as to Scotch law.

Par of Exchange between England and the following places, viz. Amsterdam, Hamburg, Paris, Madrid, Lisbon, Leghorn, Genoa, Naples, and Venice; the same being computed from the intrinsic Value of their principal Coins, by comparing Gold with Gold, and Silver with Silver, according to their Mint Regulations, and to Assays made at the London and Paris Mints. Exclusion
||
Excommunication.

Exchange also signifies a place in most considerable trading cities, where the merchants, agents, bankers, brokers, interpreters, and other persons concerned in commerce, congregate on certain days, and at certain times of the day, to confer and treat together of matters relating to exchanges, remittances, payments, adventures, assurances, freightments, and other mercantile negotiations, both by sea and land.

In Flanders, in Holland, and in several cities of France, these places are called *Bourses;* at Paris and at Lyons, *Places de Change;* and in the Hanse Towns, *Borsenhalle.* These assemblies are held with so much exactness, and merchants and traders are so indispensably required to attend at them, that a person's absence alone makes him suspected of a failure or bankruptcy. The most considerable exchanges in Europe are, first, that of Amsterdam, and, secondly, that of London, called the Royal Exchange.

Even in the time of the ancient Romans, there were places for merchants to meet, in most of the considerable cities of the empire. That which is said by some to have been built at Rome in the year of the city 259, or 493 years before Christ, under the consulate of Appius Claudius and Publius Servilius, was called *Collegium Mercatorum,* of which it is pretended there are still some remains, called by the modern Romans *Loggia* or the Lodge, and now usually the place of St George. This notion of a Roman exchange is supposed to be countenanced by the authority of Livy.

EXCHEQUER, in British jurisprudence, an ancient court of record, in which all causes concerning the revenues and rights of the crown are heard and determined, and where the crown revenues are received. It derived this name from the cloth that covered the table of the court, which was party-coloured, or chequered. See England, Part III.

Exchequer, in Scotland. See Scotland.

EXCISE (from the Belgic *acciisse,* tribute), an inland duty or impost paid sometimes upon the consumption of the commodity, or frequently upon the sale, which is the last stage before the consumption. This is doubtless, impartially speaking, the most economical way of taxing the subject; the charges of levying, collecting, and managing the excise duties, being considerably less in proportion than in other branches of the revenue. It also renders the commodity cheaper to the consumer than the charging it with customs to the same amount would do, because it is generally paid in a much later stage. But this mode of taxation has ever been unpopular. Lord Clarendon tells us, that to his knowledge the Earl of Bedford, who was made lord treasurer by King Charles I., in order to oblige his parliament, intended to have set up the excise in England; yet it never formed a part of that unfortunate prince's revenue, being first introduced, on the model of the Dutch prototype, by the parliament itself, after the rupture with the crown. Yet such was the opinion of its general unpopularity, that when in 1642 "aspersions were cast by malignant persons upon the house of commons, that they intended to introduce excises, the house for its vindication therein did declare, that these rumours were false and scandalous, and that their authors should be apprehended and brought to condign punishment." Its original establishment was in 1643, and its progress was gradual, being at first laid upon those persons and commodities where it was supposed the hardship would be least perceptible, namely, the makers and venders of beer, ale, cyder, and perry. The royalists at Oxford soon followed the example of their brethren at Westminster, by imposing a similar duty; but both sides protested that it should be continued no longer than till the end of the war, and should then be utterly abolished. The parliament at Westminster, however, soon afterwards imposed it on flesh, wine, tobacco, sugar, and such a multitude of other commodities, that it might be fairly denominated *general;* and this was done in pursuance of the plan proposed by Pym, who seems to have been the father of the excise, in his letter to Sir John Hotham, intimating, "that they had proceeded in the excise to many particulars, and intended to go on farther, but that it would be necessary to use the people to it by little and little." And afterwards, when the nation had been accustomed to it for a series of years, the succeeding champions of liberty boldly and openly declared "the impost of excise to be the most easy and indifferent levy that could be laid upon the people;" so that it continued during the whole of the usurpation. Upon the return of Charles II., as it had then been long established, and its produce was well known, some part of it was given to the crown by 12 Carol. II. as a compensation for the feudal tenures and other oppressive parts of the hereditary revenue. But from its origin to the present time its name has been odious to the people. See Taxation.

EXCLUSION, or *Bill of* Exclusion, a bill proposed towards the close of the reign of King Charles II. for the purpose of excluding the Duke of York, the king's brother, from the throne, on account of his being a Catholic.

EXCOMMUNICATION, an ecclesiastical penalty or censure, by which persons guilty of any notorious crime or offence are separated from the communion of the church, and deprived of all spiritual advantages.

Excommunication is founded on the natural right which all societies have, of excluding from their body such as violate the established laws; and it was originally instituted for preserving the purity of the church; but ambitious ecclesiastics converted it by degrees into an engine for promoting their own power, and frequently inflicted it on the most frivolous pretences.

The power of excommunication, as well as other acts of ecclesiastical discipline, was lodged in the hands of the clergy, who distinguished it into the *greater* and *lesser.*

The *lesser* excommunication, simply called *aphorismos,* separation or suspension, consisted in excluding men from the participation of the eucharist, and the prayers of the faithful. But they were not thereby expelled the church; for they had the privilege of being present at the reading of the Scriptures, the sermons, and the prayers of the catechumens and penitents. This excommunication was inflicted for lesser crimes, such as neglecting to attend the service of the church, misbehaviour in church, and the like.

The *greater* excommunication, called *panteles aphorismos,* or total separation and anathema, consisted in an absolute and entire exclusion from the church and the participation of all its rites. When any person had thus been excommunicated, notice of it was given by circular letters to the most eminent churches, that they might all confirm this act of discipline, by refusing to admit the delinquent to their communion. The consequences of this latter excommunication were terrible. The excommunicated person was avoided in civil commerce and outward conversation; no one would receive him into his house, or eat at the same table with him; and when dead, he was denied the solemn rites of burial.

The Roman pontifical takes notice of three kinds of excommunication: first, the minor, incurred by those who have had any correspondence with an excommunicated person; second, the major, which falls upon those who disobey the commands of the holy see, or refuse to submit to certain points of discipline, in consequence of which they are excluded from the church militant and triumphant, and delivered over to the devil and his angels; and, third, anathema, which is properly that pronounced by the pope against heretical princes and countries. In former ages, these papal fulminations were terrible calamities; but at present they are formidable only to a few petty states of Italy.

Excommunication, in the Greek church, cuts off the offender from all communion with the three hundred and eighteen fathers of the first council of Nice, and with the saints; consigns him over to the devil and the traitor Judas; and condemns his body to remain after death as hard as a flint or piece of steel, unless he humble himself, and make atonement for his sins by a sincere repentance. The form abounds with dreadful imprecations; and the Greeks assert, that if a person die excommunicated, the devil enters into the lifeless corpse; to prevent which, the relations of the deceased cut his body in pieces, and boil them in wine. It used to be a custom for the patriarch of Jerusalem annually to excommunicate the pope and the church of Rome; on which occasion, besides a great deal of idle ceremony, a nail was driven into the ground with a hammer, as a mark of malediction.

The form of excommunication in the church of England anciently ran thus: "By the authority of God the Father Almighty, the Son, and Holy Ghost, and of Mary the blessed mother of God, we excommunicate, anathematize, and sequester from the pale of the holy mother church," and so forth. The causes of excommunication in England are, contempt of the bishop's court, heresy, neglect of public worship and the sacraments, incontinency, adultery, simony, and the like. It is described as twofold. The lesser is an ecclesiastical censure, excluding the party from the participation of the sacraments; the greater proceeds farther, and excludes the party not only from these privileges, but from the company of all Christians. But if the judge of any spiritual court excommunicate a man for a cause of which he has not the legal cognizance, the party may have an action against him at common law, and he is also liable to be indicted at the suit of the king.

Excommunication, or the act of secluding from a participation in the mysteries of religion, was also in use under paganism. Persons thus excommunicated were forbidden to assist at or attend the sacrifices, or enter within the temples; and they were afterwards delivered over to the demons and furies of hell, with certain imprecations. This was called by the Romans *diris devovere.*

Amongst the ancient Britons and Gauls the Druids likewise made use of excommunication against rebels, and interdicted from the communion of their mysteries such as had refused to acquiesce in their decisions.

EXCREMENT, whatever is discharged out of the body of animals after digestion; or the fibrous part of the aliment, mixed with the bile, saliva, and other fluids. Urine and the fæces are the gross excrements discharged out of the bladder and stomach. The other excrements are the various humours secreted through the different pores of the body, by which secretion several useful purposes are served.

EXCRESCENCE, in *Surgery*, denotes every preternatural tumour which arises upon the skin, either in the form of a wart or a tubercle. If such tumours are born with a person, as is frequently the case, they are called *nævi materni*, or marks from the mother; but if they are large, so as to depend from the skin, like a fleshy mass, they are then called *sarcomata.*

EXCRETORY, in *Anatomy*, a term applied to certain little ducts or vessels, destined for the reception of a fluid, secreted in certain glandules and other viscera, for the excretion of it in the appropriated places.

EXCUBIÆ, in *Antiquity*, the watches and guards kept in the daytime by the Roman soldiers. They are contradistinguished from the *vigiliæ*, which were kept in the night. The *excubiæ* were placed either at the gates and entrenchments, or in the camp; for the latter there was allowed a whole *manipulus* to attend before the *prætorium*, and four soldiers to the tent of every *tribune.* The *excubiæ* at the gates of the camp, and at the entrenchments, were properly called *stationes.* One company of foot and one troop of horse were assigned to each of the four gates every day. To desert his post, or to abandon his corps of guards, was an unpardonable crime in the Roman soldier.

The *triarii*, as the most honourable class of soldiers, were excused from the ordinary watches; yet being placed opposite to the *equites*, they were obliged to have an eye over them.

EXCUSATI, in *Ecclesiastical History*, a term used to denote slaves, who, having fled to any church for sanctuary, were excused and pardoned by their masters; but the latter were obliged to take an oath to this effect before they could recover the fugitives; and, if they broke it, they were punished and fined as persons guilty of perjury.

EXEAT, in church discipline, a Latin term used for a permission which a bishop grants a priest to go out of his diocese, or an abbot to a religious person to go out of his monastery.

EXECRATION, in *Antiquity*, a kind of punishment, consisting of direful curses and marks of infamy, such as was used against Philip, king of Macedonia, by the Athenians. A general assembly of the people being called, they made a decree that the statues and images of that king, and of all his ancestors, should be demolished, and their very name erazed; that all the festivals, sacred rites, and whatsoever else had been instituted in honour of him, should be profaned; that the very places where there had been any monument or inscription to his honour should be detestable; that nothing should be set up or dedicated in them, which could be done in clean places; and, lastly, that the priests, as often as they prayed for the Athenian people, allies, armies, and fleets, should detest and execrate Philip, his children, kingdom, land and sea forces, and the whole race and name of the Macedonians.

At the taking and demolishing of cities, it was usual amongst the Jews, Greeks, and Romans, to pronounce curses upon, and load with direful execrations, those who should rebuild them.

EXECUTIVE POWER. The supreme executive power of these kingdoms is vested by our laws in a single person, the king or queen for the time being.

The executive power in Britain has a right to a negative or *veto* in parliament; that is, to refuse assent to any acts presented for that purpose, otherwise the two other branches of legislative power might become despotic.

EXECUTOR, a person nominated by a testator, to see his will and testament executed or performed, and his effects disposed of according to the tenor of such will and testament. See LAW.

EXECUTOR, in *Scotch Law*, signifies either the person entitled to succeed to the moveable estate of one deceased, or who by law or special appointment is entrusted with the administration of it.

EXECUTRY, in *Scotch Law*, is the moveable estate falling to the executor. Under executry or moveables is comprehended every thing that moves itself, or that can be moved.

EXEDRÆ, in *Antiquity*, denoted halls with many seats, where the philosophers, rhetoricians, and men of learning met for discourse and disputation. The word occurs in

Exfoliation
||
Exhaustions.

ecclesiastical writers as a general name for such buildings as were distinct from the main body of the churches, and yet within the limits of the church taken in its largest sense. Among the exedræ the chief was the baptistery.

EXEGESIS, a discourse, by way of explanation or comment, upon any subject.

EXEGETES (formed from εξηγεομαι, *to explain*), among the Athenians, persons learned in the laws, whom the judges used to consult in capital causes.

EXEGETICA, in *Algebra*, the art of finding, either in numbers or lines, the roots of the equation of a problem, according as the problem is either numerical or geometrical.

EXEMPLAR, a model or original to be imitated or copied.

Exemplar also denotes the idea or image conceived or formed in the mind of the artist, and according to which he conducts his work.

EXERCISE, amongst physicians, such movement and agitation of the body as produce salutary effects in the animal economy.

Exercise may be said to be either active or passive. Active exercise consists in walking, hunting, dancing, playing at bowls, and the like; as also in speaking and other labours of the body and mind. Passive exercise consists in riding in a coach, on horseback, or in any other manner. Boerhaave recommends bodily exercise in diseases of a weak and lax fibre. By riding on horseback, says his commentator, the pendulous viscera of the abdomen are shaken every moment, and gently rubbed as it were one against another, whilst in the mean time the pure air acts on the lungs with greater force. Sailing in a ship is also an exercise of great use to weak people. If the vessel proceeds with an even motion, by increasing perspiration it usually excites a wonderful alacrity, creates an appetite, and promotes digestion. These exercises are more especially serviceable to weak people; but, in order to strengthen the body by muscular motion, running and bodily exercises are to be used. In the latter, however, persons should begin with the most gentle, such as walking, and increase it by degrees till they come to running. Those exercises of the body are most especially serviceable which at the same time give pleasure or occupation to the mind, as tennis, fencing, and the like; for which reason, the wisdom of antiquity appointed rewards to those who excelled in gymnastic exercises, that the bodies of their youth might be prepared for enduring warlike toils.

Exercise, in military affairs, is the ranging a body of soldiers in order of battle, and making them perform the several motions and military evolutions necessary to render them expert in the use of their arms. See War.

EXERGUM, among antiquaries, a little space around or without the figures of a medal, left for the inscription, cipher, device, date, and so forth.

EXETER, a large city, the capital of the county of Devon, 170 miles from London. It rises gradually from the banks of the river Ex; and the whole city being on a declivity, it is remarkably clean, notwithstanding the narrowness of all but the principal street. The best parts are without the line of the ancient walls; and both the suburbs of Southernay and Nornay are beautiful and well built. The surrounding country is highly fruitful, affording good corn, pasture, dairy, and fattening land, and abounding in fruit, especially apples, from which the best of cider is plentifully yielded. These circumstances, with the cheapness of fish and poultry, and the salubrity of the air, contribute to attract to Exeter numerous families of easy but moderate fortune.

Exeter was formerly the emporium of the thinner kind of woollen goods, such as serges, druggets, estamines, and long ells, which were spun and woven in the towns around, and dyed and finished within the city. From thence they were shipped to Holland, Italy, and especially to Spain, and many were supplied to the East India Company; but the introduction of machinery, and the lower price of fuel in the north of England, have now nearly destroyed those branches of trade, with the exception of that for the supply of India, which is still considerable. As Exeter is a kind of metropolis for Devon and Cornwall, it has considerable internal trade, and is the channel by which these counties are supplied with many foreign commodities. The river Ex is so far navigable that, by means of locks, vessels of 150 tons burden can come up to the city; but those of greater draught of water remain at Topsham, three miles lower, and the largest of all at Exmouth, at the mouth of the river. Exeter contains a cathedral and fifteen other churches, besides several other places of worship for the separatists from the establishment. The cathedral is a magnificent pile, a part being very old, but many additions are of more recent construction, though on the plan originally formed. The western window is an object of peculiar admiration. The see includes nearly the whole of Devonshire and Cornwall. It was first founded at Bodmin, then transferred to Taunton, afterwards to Crediton, and finally, in 1094, to Exeter. The city is governed by a corporate body, consisting of the mayor, twenty-four aldermen, and other officers. Two members are returned to the House of Commons. The markets are held on Wednesday and Friday, and there is a good fish-market daily. The population amounted in 1801 to 16,827, in 1811 to 18,896, in 1821 to 23,479, and in 1831 to 28,201.

EXFOLIATION, a term used by surgeons for the separation of the dead part of a bone from the living part.

EXHALATION, a general term for all effluvia or steams raised from the surface of the earth in form of vapour.

EXHAUSTIONS, in *Mathematics*. The method of exhaustions is a way of comparing or estimating fixed magnitudes by means of variable magnitudes, which may be brought to approach or *exhaust* them more nearly than any assigned interval or remainder.

Thus, a regular polygon may be inscribed in a circle, and by repeatedly doubling the multitude of sides, or increasing it by other given laws, this variable figure may be made so to *exhaust* the circle as to leave a remainder less than any given area. And because similar polygons inscribed in different circles have always the duplicate ratio of the diameters, it has been perceived that the circles themselves must be as these exhaurient polygons, which Euclid proves strictly by the method of exhaustions.

A rectilineal figure may be inscribed in a segment of a parabola, so as to leave less of the parabola than any area assigned, and also to be nearer four thirds of the greatest inscribed triangle than any given difference. Hence Archimedes proves, by the method of exhaustions, that the segment of the parabola exceeds the triangle by one third of the same triangle.

The first lemma of Newton's *Principia* brings the method of exhaustions to general application. It is in these words:

"Quantitates, ut et quantitatum rationes, quæ ad æqualitatem tempore quovis finito constanter tendunt, et ante finem temporis illius propius ad invicem accedunt quam pro data quavis differentia, fiunt ultimo æquales.

"Si negas; fiant ultimo inæquales, et sit earum ultima differentia D. Ergo nequeunt propius ad æqualitatem accedere quam pro data differentia D: contra hypothesin."

Many authors have not rightly understood this lemma, as Horsley in his note upon it; Hutton on Prime and

Ultimate Ratios, in his *Dictionary;* and Woodhouse, *Principles of Analytical Calculation,* paragraph 105, where it is said to be "merely a definition," and, again, that "it gave a new signification to the term equality."

If our opinion be just, it gives no signification to the term equality which was not given by Euclid and Archimedes. The novelty is in giving to the word *ultimate,* or the adverb *ultimately,* an extension beyond what it ordinarily includes; as, in the technical language of the *Principia,* things are often said to be *ultimately* what, by their definition, they are incapable of becoming.

In this language, as explained by its author, an ultimate quantity, or that which a quantity ultimately becomes (*fit ultimo*), is what is otherwise called the *limit* of the quantity; that to which, repeating the words of this lemma, *tempore quovis finito constanter tendit, et ante finem temporis illius propius accedit quam pro data quavis differentia.* Thus, in the *Scholium,* after the eleventh lemma, our author says, *ad ultimas quantitatum evanescentium summas, id est, ad limites summarum.*

Few as are the words of the demonstration of this celebrated lemma, it must be concluded from them that it only concerns quantities of which it could be questioned whether they have a *fixed* difference. Applied to variables, it can therefore only compare them in some simultaneous magnitudes. Among simultaneous magnitudes, Newton, for the sake of brevity, includes limits; and, in fact, only these limits are here compared. Perhaps a slight change in the language may show more clearly the intention.

"Quantities, as also the ratios of quantities, which in any finite time soever constantly tend to equality, and before the end of that time approach nearer than any difference, have equal limits."

"If not, let their limits be unequal, and differ by D. Then the variables, in their approach, cannot come nearer than D, *contra hypothesin.*"

This may be too concise, but is fully made out in the following manner:

Let X and Y be two quantities, continually approaching, and capable of being brought nearer than any difference within a finite time. Let A be the limit of X, and B the limit of Y; that is, let A and B be fixed quantities, to which X and Y, during their approach, may be brought nearer than any difference assignable. Then shall A and B be equal.

For, if not, let $A = B + D$. And at any time during the approach of X and Y, let m be the difference of X from its limit, and n the contemporary difference of Y from its limit. And,

I. Suppose the variables to approach by the decrease of the greater and the increase of the less towards their respective limits (like a circumscribed and inscribed polygon); or $X = A + m$, $Y = B - n$. Then $X - Y = A - B + m + n = D + m + n$, so that X and Y necessarily differ by more than D, *contra hypothesin.*

II. Suppose both variables to decrease towards their limits; or $X = A + m$ and $Y = B + n$. Then $X - Y = A - B + m - n = D + m - n$.

Now if n were greater than m, we might decrease Y by a part of n, which we will call y, greater than m itself, and still greater than its part (x), the contemporary decrement of X; and putting X′ and Y′ for the variables thus decreased, we should have $X' = X - x$, $Y' = Y - y$, and thence $X - Y' = X - Y + (y - x)$; so that the difference of the variables would be augmented by bringing them nearer to their limits. Therefore n cannot be greater than m; consequently $D + m - n$ cannot be less than D, or the difference of X and Y cannot become less than D, *contra hypothesin.*

III. It only remains to examine the case where both increase towards their limits, or $X = A - m$, $Y = B - n$, and $X - Y = A - B + n - m = D + n - m$.

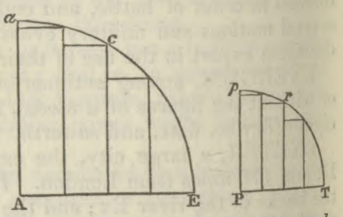
Here if m exceeded n, we might increase X by a quantity x greater than n, and still more exceeding y, the contemporary increment of Y, and putting X′ and Y′ to signify the variables thus increased, $X' - Y' = X + x - (Y + y)$, or $X' - Y' = X - Y + (x - y)$, so that the variables would again diverge. Therefore again $D + n - m$ cannot be less than D, or X and Y cannot differ by less than D, *contra hypothesin.*

If X, Y, A, B, D, m, n, x, y, represent *measures of ratios,* the proof includes the *quantitatum rationes.*

There results no absurdity from supposing the limits of two quantities which continually approach to have a difference D; but then the approaching quantities must always differ still more, contrary to one of the conditions.

By making n nothing in Case II. we make Y constant, and coincident in magnitude with B. The proposition obtained by the reasoning is, for this case, that whatever quantity A (suppose it a parabolic segment) may be an acknowledged limit of a variable X, if X can at the same time be proved to approach indefinitely to Y or B (suppose it a triangle equal to four thirds of the greatest triangle in the parabolic segment), A is equal to B. This is to prove that limits of the same variable are equal, which is neither giving a new signification to equality, nor concluding an identical proposition, nor indeed one which an ancient geometer would have admitted without formal proof. We come to a similar conclusion by making m nothing in Case III.

It is true that, in the *Principia,* when a fixed quantity is proved to be a limit to a variable, and the variable then pronounced ultimately equal to the fixed quantity, the author or editors refer to the first lemma, when reference might as well be made to the definition of ultimate quantities there implied; only (what is the main thing) the demonstration of the lemma teaches how, by admitting the limit as a particular value of the variable, we cannot produce an error measured by any fixed quantity, while if an error were admitted at all, it *must* be of fixed amount. Thus in Lemma IV. where the same multitude of rectangles is supposed to be inscribed in the two figures A*ac*E, P*pr*T, and when this multitude is indefinitely increased, and consequently the breadth of the rectangles and the remainder of the areas indefinitely diminished, each rectangle in the one figure has, by hypothesis, the same ratio to a corresponding rectangle in the other; it is concluded that this is also the ratio of the whole figures. For the ratio of the area A*ac*E to P*pr*T may be viewed as compounded of A*ac*E to the rectangles within itself, of these to the contemporary rectangles within P*pr*T, and of these latter rectangles to P*pr*T. But the first and last of the component ratios being *ultimately* of equality, the compound ratio is the constant ratio of the contemporary rectangles. For let L be the measure of the ratio of the inscribed rectangles, and let it be asserted that the compound ratio differs from L by a ratio whose measure is D. The first and last of the component ratios being ultimately of equality, their contemporary values may be made such that the measures (m and n) of the ratios by which the former exceeds equality and the latter falls below it, may be each less than D, and, *a fortiori,* their difference less than D. But $L + m - n$ is the true measure of the compound ratio; therefore L does not differ from the true measure by D.



Thus, by admitting ultimate values, no error is admitted. The method of exhaustions, which Newton's first lemma reduces to an enunciable proposition, only requires it to be allowed that fixed quantities either have a fixed difference or are equal. What is often called the principle of limits is to comprehend limits at once in the conclusion of a demonstration which does not apply to them. Newton's lemma serves to admit them through the method of exhaustions. According to the foregoing exposition, it is neither an identical proposition nor an arbitrary extension of the meaning of a term, though these inconsistent charges have both been brought against it. A and B are proved to be equal in the old signification of equality; and whilst it is said that X and Y are *ultimately* equal, X and Y are also ultimately A and B. (O. O. O.)

EXHEREDATION, in the civil law, is the father's excluding his sons from inheriting his estate.

There are fourteen causes of exheredation, expressed in Justinian's *Novellæ*, without some one of which he declares the exheredation null, and the testament inofficious, as the civilians express it. Indeed, by the ancient Roman law, the father might pronounce exheredation without any cause; but the rigour of this law was restrained and moderated by Justinian.

EXHIBITION, in *Law*, a producing or showing of titles, authorities, and other proofs, in a matter contested.

EXHIBITION, in our old writers, is used to signify an allowance of meat and drink, such as was customary amongst the religious appropriators of churches, who usually made it to the vicar incumbent. The benefactions settled for the maintaining of scholars in the universities not depending on the foundation, are also called *exhibitions.*

EXHORTATION, in *Rhetoric*, differs only from *persuasion* in that the latter principally endeavours to convince the understanding, and the former to work on the affections.

EXIGENTERS, four officers in the court of common pleas, who make exigents and proclamations in all actions where process of outlawry lies.

EXILE. Among the Romans, the word *exilium* properly signified an interdiction or exclusion from water and fire; the necessary consequence of which was, that the interdicted person had to betake himself to some other country, as there was no living without fire and water in his own. Thus Cicero observes, that the form of the sentence did not express *exilium*, but only *aquæ et ignis interdictio;* and he also remarks that exile was not properly a punishment, but a voluntarily flying from or avoiding the punishment decreed: *Exilium non esse supplicium, sed perfugium portusque supplicii.* He adds that there was no crime among the Romans, as among other nations, punished with exile; but exile was a resource of which people voluntarily availed themselves, in order to avoid chains, ignominy, famine, or death.

The Athenians frequently sent their generals and great men into exile, out of envy of their merits, or distrust of their authority and influence in the state.

EXISTENCE, that by which any thing has an actual essence, or is said to *be.* See METAPHYSICS.

EXIT properly expresses the departure of a player from the stage, when he has performed his part. The word is also used in a figurative sense, to express any kind of departure, even death.

EXITERIA, in *Antiquity*, oblations or prayers to any of the gods for a prosperous expedition or journey. There were also feasts under this denomination, which were celebrated by the Greeks with sacrifices and prayers, when their generals undertook expeditions against an enemy.

EXMOUTH, a town in Devonshire, 166 miles from London, part of the parish of Littleham, and part of Withycombe Rawleigh, in the hundred of East Budleigh. It is situated on the north side of the Ex, at its entrance into the sea. It has risen within a few years, from having become the resort of company for sea-bathing in summer, and in winter the residence of those suffering under pulmonary complaints. The air is salubrious, and the prospects around are beautiful. The population of Exmouth amounted in 1801 to 1909, in 1811 to 2294, and in 1821 to 2640.

EXODIARY, in the ancient Roman tragedy, was the person who, after the drama or play was ended, sung the *Exodium.*

EXODIUM, in the ancient Greek drama, one of the four parts or divisions of a tragedy, being as much of the piece as included the unravelling and catastrophe of the plot, and answering nearly to our fourth and fifth acts.

EXODIUM, amongst the Romans, consisted of certain humorous verses rehearsed by the exodiary at the end of the *Fabulæ Atellanæ.*

EXODIUM, in the Septuagint, signifies the end or conclusion of a feast; and, in particular, it is used for the eighth day of the feast of tabernacles, which, it is said, had a special view to the commemoration of the *exodus* or departure out of Egypt.

EXODUS, a canonical book of the Old Testament, being the second of the Pentateuch or five books of Moses; so called from the Greek word ἔξοδος, the going out or departure of the children of Israel from the land of Egypt; the history of which is delivered in this book, together with that of many miracles wrought on the occasion.

EXORCISM, the expelling of devils from persons possessed, by means of conjurations and prayers. The Jews made great pretences to this power; and Josephus tells several wonderful tales of the success of several performers in this line. According to him, a pretender named Eleazer cured many dæmoniacs by means of a root set in a ring. This root, with the ring, was held under the patient's nose, and the devil forthwith evacuated the tenement of which he had taken possession. The most part of the conjurors of this class were impostors, each pretending to a secret nostrum or charm, which was an overmatch for the devil.

Exorcism forms no inconsiderable part of the religious system of the church of Rome, the rituals of which forbid the exorcising of any person without the bishop's leave. The ceremony is performed at the lower end of the church, towards the door. The exorcist first signs the possessed person with the figure of the cross, makes him kneel, and sprinkles him with holy water; then follow the litanies, psalms, and prayer; after which the exorcist asks the devil his name, and adjures him by the holy mysteries of the Christian religion not to afflict the person possessed any more. Then, laying his right hand on the dæmoniac's head, he repeats the form of exorcism as follows: "I exorcise thee, unclean spirit, in the name of Jesus Christ; tremble, O Satan, thou enemy of the faith, thou foe of mankind, who hast brought death into the world, who hast deprived men of life, and hast rebelled against justice; thou seducer of mankind, thou root of evil, thou source of avarice, discord, and envy." Houses and other places supposed to be haunted by unclean spirits are likewise exorcised; and the ceremony is much the same as that for persons possessed.

EXORCISTS, in *Ecclesiastical History*, an order of men in the ancient church, whose employment it was to exorcise or cast out devils.

EXORDIUM, in *Oratory*, is the preamble or beginning, which serves to prepare the audience for the rest of the discourse. Exordiums are of two kinds, either just and formal, or vehement and abrupt. The latter are more suitable on occasions of extraordinary joy, indignation, or excitement.

EXOTERIC and Esoteric are terms denoting *external* and *internal*, and applied to the double doctrine of the ancient philosophers, particularly those of the Peripatetic school. The one was public or *exoteric;* the other secret or *esoteric.* The first was that which they openly professed and taught to the world; the latter was confined to a small number of chosen disciples. This method was derived originally from the Egyptians, who, according to the united testimony of Herodotus, Diodorus Siculus, Strabo, Plutarch, and others, had a twofold philosophy; one secret and sacred, another public and common. The same practice also obtained amongst the Persian Magi, the Druids of the Gauls, and the Brahmins of India. The Egyptian priests with whom it originated sustained the character of judges and magistrates, and probably introduced this distinction with a view to the public welfare, and to serve the purposes of legislation and government. Clemens Alexandrinus informs us, that they communicated their mysteries principally to those who were concerned in the administration of the state; and Plutarch confirms this declaration. Others, however, have supposed that they invented the fables of their gods and heroes, and the external ceremonies of their religion, to disguise and conceal natural and moral truths; but whatever may have been the motive of their practice, it was certainly applied to political purposes.

EXOTIC, a term properly signifying *foreign* or *extraneous*, that is, brought from a remote or strange country. In this sense we sometimes say *exotic* or *barbarous terms*, and the like. The word is derived from the Greek εξω, or εξωθεν, *extra*, without, or on the outside.

Exotic is chiefly applied to plants which are natives of foreign countries, particularly those brought from the East or West Indies, and which do not naturally grow in Europe.

EXPANSION, in *Physics*, denotes the enlargement or increase of bulk in bodies, chiefly by means of heat. This is one of the most general effects of that subtile principle, and common to all bodies whatever, whether solid or fluid. In some few cases, indeed, bodies seem to expand as they grow cold, as water in the act of freezing; but this is found to be owing to a new arrangement of the particles, or to crystallization, and is not at all a regular and gradual expansion like that of metals, or any other solid or fluid substance by means of heat. In certain metals also, an expansion takes place when they pass from a fluid to a solid state; but this too is not to be accounted any proper effect of cold, but of the arrangement of the parts of a metal in a peculiar manner; and it is therefore to be ascribed to a kind of crystallization.

EXPECTATION, in the doctrine of chances, is applied to any contingent event, and is capable of being reduced to the rules of computation. Thus a sum of money in expectation when a particular event happens, has a determinate value before that event arrives; so that if a person is to receive any sum, say L.10, when an event takes place which has an equal probability of happening and failing, the value of the expectation is half that sum, or L.5; and in all cases the expectation of obtaining any sum is estimated by multiplying the value of the sum expected by the fraction which represents the probability of obtaining it. The expectation of a person who has three chances in five of obtaining L.100, is equal to $\frac{3}{5} \times 100$, or L.60, and the probability of obtaining L.100 in this case is equal to $\frac{60}{100} = \frac{3}{5}$.

Expectation of Life signifies that share or number of the years of human life, which a person of any given age may expect to enjoy upon an equality of chances. See Annuities.

EXPERIENCE, a kind of knowledge acquired by long use, without any teacher or particular course of inquiry.

EXPERIMENTAL Philosophy is that which has its foundation in experience, wherein nothing is assumed as a truth but that which is founded upon ocular demonstration, or which cannot be denied without violating the common sense and perceptions of mankind. See Philosophy and Physics.

EXPERIMENTUM Crucis, a capital, leading, or decisive experiment, which is so termed, either on account of its being like a cross, or direction-post placed in the meeting of several roads, guiding men to the true knowledge of the nature of that thing they are inquiring after; or on account of its being a kind of torture, by means of which the nature of the thing is as it were extorted by force.

EXPIATION, a religious act, by which satisfaction or atonement is made for the commission of some crime, the guilt done away, and the obligation to punishment cancelled.

Expiations amongst the heathens were of several kinds, as sacrifices and religious washings. They were used for effacing a crime, or averting any calamity, and on numberless other occasions, as purifying towns, temples, and sacred places, and armies before and after battle; and they were performed in behalf of whole cities, as well as of particular persons.

The method of expiation amongst the Jews was chiefly by sacrifice, whether for sins of ignorance, or in order to purify themselves from certain pollutions.

Feast of Expiation, amongst the Jews, called by our translators the Day of Atonement, was held on the tenth day of Tisri, or the seventh month of the Jewish year, answering to part of our September and October. On that day the high-priest entered into the holy place, confessed his sins, and, after several ceremonies, made an atonement for all the people, in order to cleanse them from their sins.

EXPLOSION, a sudden and violent expansion of an aerial or other elastic fluid, by which it instantly throws off any obstacle that happens to be in the way, sometimes with great force, and in such a manner as to produce astonishing effects upon adjacent objects.

Explosion differs from expansion, which is a gradual and continuous power, acting uniformly for some time, whereas the former is always sudden, and only of momentary duration. The expansions of solid substances do not terminate in violent explosions, on account of their slowness, and the small space through which the metal, or other expanding substance, moves; though their strength may be equally great with that of the most active aerial fluids. Thus we find, that though wedges of wood, when moistened, will cleave solid blocks of stone, they never throw them to any distance, as is the case with gunpowder. On the other hand, it is seldom that the expansion of any elastic fluid bursts a solid substance without projecting the fragments of it to a considerable distance. The reasons of this are, first, the immense velocity with which the aerial fluids expand, when affected by a considerable degree of heat; and, secondly, their celerity in acquiring heat and being affected by it, which is much superior to that of solid substances. Thus, air, heated as much as iron when brought to a white heat, is expanded to four times its bulk; but the metal itself will not be expanded the five hundredth part of its bulk. In the case of gunpowder, which is a violent and well-known explosive substance, the velocity with which the flame moves is calculated by Mr Robins, in his *Treatise upon Gunnery*, to be no less than seven thousand feet in a second, or little less than seventy-nine miles per minute. Hence the impulse of the fluid is inconceivably great, and the obstacles on which it strikes are hurried off with vast velocity, though much less than that just mentioned; for a cannon bullet, with the greatest charge of powder that can be conveniently given, does not move at a greater rate than two thousand four hundred feet per second, or little more than twenty-seven miles per minute. The velocity of the bullet, again, is promoted by the sudden propagation of the heat through the whole body of air, as soon as it is extricated from the materials of which the gunpowder is made; so that it is enabled to strike all at once, and thus greatly to augment the momentum of the ball. That this contributes much to the force of the explosion, is evident from what happens when powder is wetted or mixed with any substance, which prevents its taking fire all at once. In this case the force of the explosion, even when the same quantity of powder is made use of, cannot be compared to that of dry powder.

Upon these principles we may conclude that the force of an explosion depends, first, on the quantity of elastic fluid to be expanded; secondly, on the velocity it acquires by a certain degree of heat; and, thirdly, on the celerity with which the degree of heat affects the whole of the expansive fluid. These three take place in the greatest perfection where the electric fluid is concerned, as in cases of lightning, earthquakes, and volcanoes. In violent lightning, where the electric fluid collects itself into balls, the strength of the explosion is proportional to the quantity. Every one has heard of the prodigious effects of lightning when it happens to strike buildings, trees, or even the most solid rocks; and in some cases, where the quantity of electricity is still greater than in any flash of lightning, we hear of still more tremendous consequences ensuing. Dr Priestley gives an instance of a large fire-ball, or quantity of electric matter, rolling on the surface of the sea, which, after rising up to the topmast of a ship of war, burst with such violence, that the explosion resembled the discharge of hundreds of cannon fired at once. Great damage was done by it; but there is not the least doubt that most of its force was spent on the air, or carried down to the sea by the mast and iron work of the ship. Considering, indeed, that in all cases a great part of the force of electrical explosions is dissipated in this manner, it may reasonably be doubted whether they can be measured by any method applicable to the mensuration of other forces.

In those cases where the electrical matter acts like common fire, the force of the explosions, though exceedingly great, is capable of mensuration by comparing the distances to which the bodies are thrown with the weight of such bodies. This is most evident in volcanoes, where the projections of the burning rocks and lava manifest the greatness of the power, at the same time that they afford a method of measuring it. By means of the electric fire which kindles the volcanoes, the aerial fluids are suddenly restored to their elastic state; and not only so, but their natural elasticity is greatly augmented, so that the explosions take place with great violence. The case is the same with gunpowder.

Next in strength to the aerial vapours are those of aqueous and other liquids. The most remarkable effects of these are observed in steam-engines; but there is one particular case from which it has been inferred that aqueous steam is vastly stronger than the flame of gunpowder. This is when water is thrown upon molten copper; for here the explosion is so strong as almost to exceed imagination; and the most terrible accidents have been known to happen from such a slight cause as one of the workmen spitting in the furnace where copper was being melted.

In explaining the phenomenon in question, Dr Black supposes that the mere heat of the metal applied to the aqueous steam produces the explosion; and in proof of this he alleges, that copper imbibes a greater quantity of heat during fusion than any other metal. Aqueous steam, however, seems to be too slow for producing such sudden and violent effects. Explosions, it is true, will be occasioned by it, but then it must be confined for a considerable time; whereas the effects of water thrown upon molten copper are instantaneous.

It may now be asked, why such explosions do not take place when water is thrown upon the surface of any other metal, for instance iron, when in a state of fusion? In answer to this it may be observed, that though water is decomposed by being applied to red-hot iron in the form of steam, yet there is a possibility, that when the same element is applied in substance to the fluid metal, no decomposition may ensue. Something like this indeed happens with copper itself; for, notwithstanding the violent effects which take place on the contact of water in substance with the molten metal, no explosion happens from aqueous steam being blown upon its surface. On the contrary, the upper part of the metal is thus cooled, and forms itself into cakes, which are afterwards taken off, and new ones formed in the same manner. Neither does aqueous steam affect red-hot copper in the manner that it does iron in the same state. A decisive proof that the explosion is not occasioned by the mere heat of the aqueous steam may be deduced from the example of molten glass, which produces no explosion though we pour water upon it in that state; and yet the heat of glass in a state of fusion is undoubtedly equal at least to that of molten copper. It may be observed, however, that in all cases where a very hot body is thrown upon a small quantity of water in substance, an explosion will follow; but here the water is confined, and suddenly rarefied into steam, which cannot escape without throwing off the body which confines it. Examples of this kind frequently occur where masons or other mechanics are employed in fastening cramps of iron into stones; if there happen to be a little water in the hole into which the liquid lead is poured, the latter will fly out in such a manner as sometimes to occasion serious accidents. Occurrences of this kind have sometimes happened in founderies, when large quantities of molten metal have been poured into wet moulds. In these cases, the sudden expansion of the aqueous steam throws out the metal with great violence; and if any decomposition take place at the same time, so as to convert the aqueous into an aerial vapour, the explosion will be still greater.

To this last kind of explosion we must refer that which takes place on pouring cold water into boiling or burning oil or tallow. Here the case is much the same whether we pour the oil on the water, or the water on the oil. In the former case, the water, which lies at the bottom, is rarefied into steam, and explodes; in the latter, it sinks down through the oil by its superior specific gravity, and explodes as it passes along. In either case, however, the quantity of aqueous fluid must be but small in proportion to that of the oil; a very great quantity would put out the flame, or destroy the heat, in whatever way it might be applied.

Another kind of explosion is that which takes place in solid substances, where we can scarcely suppose either aqueous or aerial vapours to be concerned. The most remarkable of these are the "volcanic bombs" mentioned by Sir William Hamilton in his account of the great eruption of Vesuvius in the year 1779. They were large pieces of lava, and burst like bombs as they fell to the ground; but he does not inform us whether their bursting was attended with any great violence or not. Other examples are the bursting of electrical globes when put in motion; of other glass vessels exploding spontaneously, and seemingly without any cause; and the bursting of large cast metal vessels in the act of cooling. These are all so similar to one another, that it is probable they depend on one general cause; and all of them agree in this, that the extreme parts are considerably cooled, whilst the internal remain very hot.

The effects of explosions, when violent, are felt at a considerable distance, by reason of the concussions they give to the atmosphere; for all of them act upon the atmospherical fluid with the same force which they exert upon terrestrial substances subjected to their action. Sir William Hamilton relates, that in consequence of the explosions of Vesuvius in 1767, the doors and windows of the houses at Naples flew open if unbolted, and one door was burst open though it had been locked; and the same thing happened several years ago, when the Stobbs powder-mills, near Dalkeith, containing several tons of powder, blew up.

EXPONENT, in *Algebra*, the same with index.

Exponent is also used in arithmetic, in the same sense as index or logarithm.

Exponential Calculus, the method of differencing, or finding the fluxions of exponential quantities, and of summing up those differences, or finding their fluents.

Exponential Curve is that the nature of which is defined or expressed by an exponential equation; as the curve denoted by $a^x = y$, or by $x^x = y$.

Exponential Equation is one in which is contained an exponential quantity; as the equation $a^x = b$, or $x^x = ab$, and the like.

Exponential Quantity is that the power of which is a variable quantity; as the expression a^x, or x^y. Exponential quantities are of several degrees and orders, according to the number of exponents or powers.

EXPOSING, the act of putting out a thing to public view. In the Roman Catholic church the sacrament is said to be *exposed*, when it is shown in public uncovered, on festival days and during the time of plenary indulgences.

Exposing of Children, a barbarous custom practised by most of the ancient nations, excepting the Thebans, who had an express law by which it was made capital to expose children, and at the same time ordained that such as were not in a condition to educate their offspring should bring them to the magistrates, that they might be brought up at the public expense. Amongst the other Greeks, when a child was born, it was laid on the ground; and if the father designed to educate it, he immediately took it up, but if he forbore to do so, the child was carried away and exposed. The Lacedæmonians indeed had a different custom: with them all new-born children were brought before certain persons, who were among the gravest in their own tribes, by whom the infants were carefully examined; and if the latter were found lusty and well favoured, orders were given for their education, and a certain proportion of land allotted for their maintenance; but if weakly or deformed, they were ordered to be cast into a deep cavern in the earth, near the mountain Taygetus, as it was thought neither for the good of the infants themselves nor for the public interest, that defective children should be brought up. Many persons exposed their children only because they were not in a condition to educate them; and it was the unhappy fate of daughters especially to be thus treated, as it required more to educate and settle them in the world than sons.

The parents frequently tied jewels and rings to the children whom they exposed, or any other thing by which they might afterwards discover them, if Providence provided for their safety; or perhaps the design was either to encourage such as found them to nourish and educate them, if alive, or to give them human burial if dead. The places where it was usual to expose children were such as people frequented most. This was done in order that they might be found and taken up by compassionate persons who were in circumstances to defray the expense of their education. With this intention the Egyptians and Romans chose the banks of rivers, and the Greeks the highways and thoroughfares.

EXPOSITION, in general, denotes the setting a thing open to public view.

Exposition, in a literary sense, is the explaining an author, passage, writing, or the like, and setting the meaning in an obvious and clear light.

EXPOSITOR, or Expository, a title which some writers have given to a lesser kind of dictionary or vocabulary, serving to expound or explain the meaning of the obscure or difficult words of a language. It is also used in the same sense with commentary and paraphrase.

EX-POST-FACTO, in *Law*, denotes something done after another thing that was done before.

EXPOSTULATION, in *Rhetoric*, an address to a person who has done another some injury, representing the wrong in the strongest terms, and demanding redress.

EXPRESSED Oils, such oils as are obtained from bodies by pressure.

EXPRESSION, in *Rhetoric*, the elocution, diction, or choice of words in a discourse.

Expression, in *Painting*, a natural and lively representation of the subject, or of the several objects intended to be shown. The expression consists chiefly in representing the human body and all its parts in the action suitable to it; in exhibiting the several passions proper to the figures; and in observing the motions they impress on the external parts.

EXSICCATION (formed from *ex*, and *siccus*, dry), in *Chemistry*, the act of drying up or evaporating the moisture of a thing.

EXSPIRATION, in *Physiology*, that part of respiration by which the air is expelled or driven out of the lungs.

EXTASY, a transport which suspends the functions of the senses, by the intense contemplation of some extraordinary or supernatural object.

Extasy, in *Medicine*, a species of catalepsy, when a person perfectly remembers, after the paroxysm is over, the ideas which he conceived during the time it lasted.

EXTENSION, in *Philosophy*, one of the common and essential properties of body; or that by which it possesses or occupies some part of universal space, which is called the place of that body. See Metaphysics.

EXTENSOR, an appellation given to several muscles, from their extending or stretching the parts to which they belong.

EXTENT, in *Law*, is used in a double sense. Sometimes it signifies a writ or command to the sheriff for the valuing of lands or tenements; and sometimes the act of the sheriff, or other commissioner, upon this writ.

EXTERNAL, a term of relation applied to the surface or outside of a body, or that part which appears or presents itself to the eye or touch, in contradistinction to internal.

External is also used to signify any thing that is without a man, or that is not within himself, particularly in his mind; in which sense we say, external objects, external nature, and the like.

EXTIRPATION, formed from *ex*, and *stirps*, a root, the act of pulling up or destroying a thing to the very roots. Amongst the prayers of the Roman Catholic jubilee, there is one for the extirpation of heresy.

EXTISPEX, in *Antiquity*, the person who drew presages from viewing the entrails of animals offered in sacrifice.

EXTORTION is an illegal wresting of any thing from a person, either by force, menace, or authority.

EXTRACTION, in *Chemistry* and *Pharmacy*, the operation by which essences, tinctures, and the like, are drawn from natural bodies.

Extraction, in genealogy, implies the stock or family from which a person is descended.

Extraction of Roots, in *Algebra* and *Arithmetic*, is the method of finding the roots of given numbers or quantities. See Algebra and Arithmetic.

EXTRAORDINARII, amongst the Romans, was a body of men consisting of the third part of the foreign horse and a fifth of the foot, which was separated from the rest of the forces borrowed from the confederate states with great policy and caution, in order to prevent any design which they might possibly entertain against the natural forces. A more choice body of men were drawn from among the *extraordinarii*, under the name of *ablecti*.

EXTRAORDINARY, something out of the common course.

Extraordinary *Couriers* are those sent expressly on some urgent occasion.

Extraordinary Ambassador, or envoy, is one who is sent to treat or negotiate some special and important affair, as a marriage, a treaty, confederacy, or even on occasion of some ceremony, as condolence, congratulation, and the like.

A gazette, journal, or other newspaper extraordinary, is that which is published after some notable event, containing the detail or particulars thereof.

EXTRAVAGANTES, a name given to those decretal epistles which were published from the Clementines. They were so called, because at first they were not digested or arranged with the other papal constitutions, but seemed to be as it were detached from the canon law. They continued to be called by the same name when they were afterwards inserted in the body of the canon law. The first *extravagantes* were those of John XXII. successor of Clement V. The last collection was brought down to the year 1483, and was called the *common extravagants*, notwithstanding that they were likewise incorporated with the rest of the canon law.

EXTRAVASATION, in contusions, fissures, depressions, fractures, and other accidents of the cranium, is when one or more of the blood-vessels, which are distributed in the *dura mater*, is broken or divided, by which means there is such a discharge of blood as greatly oppresses the brain, and disturbs its office, frequently bringing on violent pains, and at length death itself, unless the patient be timeously relieved.

EXTREME is applied to the last and outermost part of any thing, or that which finishes and terminates it on one side.

Extremes, in *Logic*, denote two terms of a syllogism, the predicate and subject. They are called *extremes*, from their relation to another term, which is a medium or mean between them. The predicate, as being likewise contained in the first proposition, is called the *majus extremum* or greater extreme; and the subject, as being put in the second or minor proposition, is called the *minus extremum* or lesser extreme. Thus, in the syllogism, "Man is an animal; Peter is a man; therefore Peter is an animal;" the word *animal* is the greater extreme, *Peter* the less extreme, and *man* the medium.

Extreme *and mean Proportion*, in *Geometry*, is when a line is so divided, that the whole line is to the greater segment as that segment is to the other; or, as it is expressed by Euclid, when the line is so divided that the rectangle under the whole line, and the lesser segment, is equal to the square of the greater segment.

EXTRINSIC, among metaphysicians, is taken in various senses. Sometimes it signifies that which does not belong to the essence of another; in which sense the efficient cause and end of a thing are said to be extrinsic. Sometimes it signifies that which is not contained within another; in which sense those causes are called extrinsic which introduce something into a subject from without, as when a fire introduces heat. Sometimes it signifies a thing added or applied to another; in which sense accidents and adherents are said to be extrinsic to the subjects to which they adhere. Sometimes the vision is said to be extrinsic from some form which does not exist in it, but is adjacent to it, or by some means or other without it.

EXUVIÆ, among naturalists, denote the cast off parts or coverings of animals, as the skins of serpents, caterpillars, and other insects. It is also applied to shells and other marine bodies, frequently found in the bowels of the earth.

EY, in our old writers, the same with *insula*, an island; from which comes *eyet*, a small island or islet, vulgarly called *eyght*.

EYE, in *Anatomy*. See Anatomy and Optics.

Eye, a borough town of the county of Suffolk, ninety miles from London, in the hundred of Hartismere. It is situated in a level country, and nearly surrounded with a small stream. There is a good market place, but the streets are neither wide nor well built. The greater portion of the town belonged to the late Marquis Cornwallis, but since his death has been sold to Sir Edward Kerrison. There was formerly some trade in spinning worsted, and in making inferior bone-lace; but these have been destroyed by the introduction of machinery. Two members were returned to the House of Commons, but since 1832 it sends only one. There was formerly a Benedictine monastery, the chapel of which, a fine building, is now the parish church. The market is held on Saturday. The population amounted in 1801 to 1734, in 1811 to 1893, in 1821 to 1882, and in 1831 to 2313.

EYEMOUTH, a town of Berwickshire, in Scotland, situated at the embouchure of the river Eye, from which circumstance it takes its name. Eyemouth lies seven miles from Berwick. It is a place of considerable antiquity, and enjoys the distinction of being a burgh of barony. It was at an early period of some importance; first, on account of its possessing a fort of great strength, which, however, is now destroyed; and, secondly, from the circumstance of its being the first harbour in the Scottish territory reached by vessels sailing from England, or along the English coast. On this account it no doubt must have frequently become a place of refuge and shelter to vessels, whether from hostile pursuit or storms at sea. Eyemouth still derives advantages from its harbour, which is well fitted for the reception of vessels in distress; and from it is exported a great deal of country produce. The town also possesses a distillery. The population amounted in 1821 to 1165, and in 1831 to 1181.

EYNAPOOR, a town of Hindustan, in the province of Bejapoor, belonging to the Mahrattas, twelve miles south-east from Merritch. It is of considerable size, and contains some Mahommedans, who subsist on grants of charitable lands. Long. 75. 10. E. Lat. 16. 50. N.

EYRIE, in *Falconry*, a brood or nest; also a place where hawks build and hatch their young.

EZEKIEL, a canonical book of the Old Testament, referring chiefly to the degenerate manners and corruptions of the Jews at the time when it was written. It abounds with fine sentences and rich comparisons, and discovers much learning in regard to profane matters.

Ezekiel was carried captive to Babylon with Jehoiachin, and began his prophecies in the fifth year of the captivity. He was contemporary with Jeremiah, who prophesied at the same time in Judæa, and foretold many events, particularly the destruction of the temple, the fatal catastrophe of those who revolted from Babylon to Egypt, and the happy return of the Jews to their native land.

EZETOVA, a river of Asiatic Russia, which runs into the estuary of the Oby, in long. 74. 14. E. and lat. 67. 50. N.

EZRA, a canonical book of the Old Testament, comprehending the history of the Jews from the time of Cyrus's edict for their return, till the twentieth year of Artaxerxes Longimanus. It specifies the number of Jews who returned, and Cyrus's proclamation for the rebuilding of the temple, together with the laying of its foundation, the obstruction which it met with, and the finishing of the sacred edifice in the reign of Darius.

The books of Ezra, called in the English version the *First and Second Books of Esdras*, though held by some, particularly the Greeks, as canonical, are thrown by the English church into the number of apocryphal books, as they are only extant in Greek.

F.

F, THE fourth consonant and sixth letter of the alphabet. The letter F is borrowed from the digamma or double gamma, F, of the Æolians, as is evident from the inscription on the pedestal of the Colossus at Delos; and though this letter is not found in the modern Greek alphabet, yet it was in the ancient one, whence the Latins received and transmitted it to us. It is formed by a strong expression of the breath, and joining at the same time the upper teeth and under lip. It has but one sort of sound, which has a great affinity with *v* and *ph*, the latter being written for it by us in all Greek words, as *philosophy*, though the Italians write the same term *filosofia*. The Romans for some time used an inverted F, instead of V consonant, which had no peculiar figure in their alphabet. Thus, in inscriptions we meet with TERMINAℲIT, DIℲI, and so on. Lipsius and others say, that it was the Emperor Claudius who introduced the use of the inverted digamma or Ⅎ; but it did not long subsist after his death; for Quintilian observes, that it was not used in his time. F or FA, in *Music*, is the fourth note in rising in this order of the gamut, *ut*, *re*, *mi*, *fa*. It likewise denotes one of the Greek keys in music, destined for the bass. F, in physical prescription, stands for *Fiat*, or Let it be done; thus, *f. s. a.* signifies *fiat secundum artem*. F was also a numeral letter signifying forty; according to the verse,

> Sexta quaterdenos gerit quæ distat ab alpha.

And when a dash was added at top, thus, $\bar{\text{F}}$, it signified forty thousand. In the civil law, two f's joined together thus, *ff*, signify the Pandects. In the law of England, F was a stigma or brand put upon felons (by stat. 4 Henry VII. c. 13) with a hot iron, on their being admitted to the benefit of clergy.

FABIAN, or FABYAN, ROBERT, an alderman of the city of London, and sheriff in the year 1493, was a person of some learning, a tolerable poet, and author of a Chronicle of England and France, entitled *The Concordance of Histories*, in two volumes folio, and containing several curious particulars, not elsewhere to be found, relative to the city of London. Stowe calls it "a painful labour, to the great honour of the city and of the whole realm." We are told that Cardinal Wolsey caused as many copies of this book as he could procure to be burned, because the author had made too clear a discovery of the large revenues of the clergy. Fabyan died in 1512. There have been five editions of his works, the first of which was printed by Pynson, in 1516; the second by Rastell, in 1533; the third by Reynes, in 1542; and the fourth by Kingston, in 1559, all in folio; whilst the fifth forms part of the series of Chronicles edited by Ellis, and is reprinted from Pynson's edition, with various collations and improvements.

FABII, a noble family at Rome, of Sabine origin, said to have derived its name from *faba*, a bean, because some of its ancestors had cultivated that pulse. It is a curious circumstance, to which the annals of the Roman republic afford no parallel, that for seventeen consecutive years, from 495 to 479 B. C., one of the seats in the consulship was always filled by members of this house. At this period they were firm adherents of the aristocratic party, and exerted all their influence to support their privileges; but at last, convinced of the fatal consequences that must ensue to their country from an obstinate resistance to the wishes of the great body of the nation, the Fabii changed the policy of their family, and joined the popular party. When they found themselves regarded as traitors and apostates, they came to the resolution of leaving, with their dependents and adherents, a place where they could no longer live in peace, and of founding a settlement which might at least be of use to the people whom they were so intimately allied to by blood and birth. It is in this way that we explain the fact of their being found near Veii. We may infer from Gellius (xvii. 21), that they were not merely an advanced guard, occupying a fort in the enemy's country, but that they had a settlement on the banks of the Cremera. Here the whole family was destroyed by the Veientes, 477 B. C. Only one remained to perpetuate the name, whose tender years, according to Livy, had kept him at Rome; but as he was consul ten years afterwards, we must regard this statement as purely legendary.

FABIUS PICTOR, the father of Roman history, respecting whom we know but little. In the interval between the first and second Punic wars we find him taking an active part in the subjugation of the Gauls in the north of Italy (225 B. C.); and after the battle of Cannæ (216 B. C.), he was employed by the Romans to proceed to Delphi, in order to consult the oracle of Apollo. But it is as an historian that he is entitled to our attention; as the earliest of the Roman annalists who set the example of writing the history of his country in prose. The rude muse of Nœvius had already celebrated in verse the glory acquired by the Roman arms in the first Punic war, and Ennius had clothed the annals of his adopted country in the language of poetry. The sources from which Fabius derived his history were no doubt the annals of the pontiffs, who were in the habit of noting on a tablet the remarkable events of each year, such as prodigies, eclipses, campaigns, triumphs, and the deaths of illustrious men; and these were afterwards collected into a book. This custom continued till the pontificate of P. Mucius and the times of the Gracchi. Such was the foundation for his history; and his style seems to have partaken much of the dry and jejune character of the memoirs which he copied. Polybius has expressed a doubt respecting their credibility, but, we think, without sufficient reason. That he should have copied from a Greek writer, Diocles of Alexandria, as Dionysius hints, carries with it its own refutation; but it is a curious fact that he wrote his annals in the Greek as well as Latin language. To what period he brought down his history we are unable to determine. Livy speaks of his death 169 B. C. (Molleri *Diss. de Q. Fabio Pictore*, Altorf. 1689; Lachman, *De Fontib. Livii*; Fabric. *Bibl. Lat.*)

Fabius *Maximus Verrucosus*, one of the most distinguished men whom Rome produced, the principal events of whose life are included between 233 and 203 B. C. He first makes his appearance in history as the conqueror of the Ligurians, who had long braved the power of Rome; and though we have no account of his proceedings from this period down to the beginning of the second Punic war, he must have no doubt taken a prominent part in public affairs, as he was then appointed to head the embassy (219 B. C.) sent to Carthage to inquire whether that state approved of Hannibal's proceedings in attacking Saguntum. The answer proved unsatisfactory; when Fabius, assuming the haughty dignity of a Roman senator, and folding up his cloak so as to form a cavity, thus addressed the nobles of Carthage: "Hic vobis bellum et pacem portamus; utrum placet sumite." Being answered that he might give which he pleased, he indignantly exclaimed, "Then I denounce war against you;" and the deputies returned to Rome to state the result of their mission. The disastrous campaign on the Trebia, and the defeat on the banks of the Thrasymene Lake, must have warned Rome that her successful resistance to Hannibal, and even her very existence, mainly depended on the wisdom of the general to whom she had entrusted her troops. Every thing pointed out Fabius as the person on whom the fate of Rome ought to be allowed to depend. The senate appointed him dictator; and the fearless character of Minucius probably induced Fabius to make him, as master of the horse, second in command. The proceedings of Fabius did not eventually disappoint the expectations of his countrymen. The grand object of his policy was to weary out and exhaust the army of Hannibal, without the risk of a general engagement; and so closely did he adhere to the plan which he had laid down for himself, that he received from this circumstance the name of Cunctator. His slow and cautious policy by no means suited the ardent spirit of the Romans, and more particularly that of Minucius, who began to ridicule the proceedings of Fabius, and, when he was absent at Rome, took the opportunity of attacking the enemy, and came off victorious. This tended only more strongly to confirm the opponents of Fabius in their opinion; and Varro, who was at this time exerting his utmost to acquire notoriety, was the only person who had boldness or impudence enough to propose to the people that Minucius should be made equal in command with Fabius. The result was exactly such as might have been anticipated. Minucius engaged in battle with Hannibal, and his army would have been cut to pieces, but for the opportune arrival of Fabius. Minucius seems to have had the moral courage to confess his folly, and cheerfully to submit to the orders of Fabius. At the end of six months he resigned his command.

But it was not long before Rome was again obliged to have recourse to the experience of Fabius. After the defeat at Cannæ (216 B. C.), he was appointed, along with Marcellus, to the command of the armies; Fabius being called *the shield*, and Marcellus *the sword*, of the republic. He laid siege to the important city of Capua; and when Hannibal marched towards Rome, threatening the city itself, Fabius remained firmly at his post, trusting in the known bravery of his fellow-citizens. Again, in his fifth consulship, we find him taking the city of Tarentum; and when it was proposed, towards the conclusion of the war, that Scipio should pass into Africa, Fabius was decidedly opposed to the scheme. But he did not live to witness the final success of Scipio, having died at an advanced age, 203 B. C. Plutarch has written his life; and many facts respecting him may be gathered from Livy, xxi.–xxx.

FABLE, a tale or feigned narrative, disguised under allegory, and designed both to amuse and instruct.

Fable is also used for the plot of an epic or dramatic poem; being, according to Aristotle, the principal part, and, as it were, the soul of the poem. See Poetry.

FABRIANO, Gentile da, an historical painter, was born at Verona in 1332, and became a disciple of Giovanni da Fiesole. In that early age of painting he rendered himself famous, and was employed to adorn a great number of churches and palaces at Florence, Urbino, Siena, Perugia, and Rome, but particularly in the Vatican; and one picture of his, representing the Virgin and Child, attended by Joseph, which is preserved in the church of Santa Maria Maggiore, was highly commended by Michel Angelo. By order of the doge and senate of Venice, he painted a picture in the great council chamber, which was considered as so extraordinary a performance, that his employers granted him a pension for life, and conferred upon him the highest honour of their state, namely, the privilege of wearing the habit of a noble Venetian. He died in 1412.

FABRIANO, a city of the papal delegation of Macerata, in Italy, on the river Giano. It is the seat of a bishop, has nine monasteries, nine nunneries, and 7224 inhabitants, who are occupied in making paper and preparing parchment. The paper made here is celebrated throughout Italy.

FABRICIUS, George, a Latin poet and historian, was born at Kemnitz, in Germany, on the 24th April 1516. He began his studies in his native place, and completed them at Freyberg and at Leipsic, where he was preceptor to Wolfgang, and also to Philip and Antony Werter. He travelled into Italy with the elder of his pupils, and on his return to Germany in 1553, was appointed director of the college of Meissen, where he died on the 13th July 1571. In his poetical compositions, which obtained for their author considerable distinction, he affected not to employ any word which had the slightest flavour of paganism; and he blamed those poets who had in their works introduced the pagan divinities. All that he wrote on the history of his country is, in the judgment of Niceron, estimable for research and accuracy; and Lenglet Dufresnoy pronounces a similar opinion. The following list includes the principal works which he published, either as author or as editor: 1. *Terentii Afri Comœdiæ sex cum castigatione duplici Joannis Rivii et G. Fabricii*, Strasburg, 1548, in 8vo; 2. *Roma, sive Liber utilissimus de veteris Romæ situ, regionibus, viis, templis, aliisque ædificiis*, Bâle, 1550, in 8vo; 3. *Virgilii Opera cum commentariis Servii et T. C. Donati*, Bâle, 1551, in fol.; 4. *Virgilii Opera a Fabricio castigata*, Leipsic, 1551, 1591, in 8vo; 5. *Poëmatum Sacrorum libri quindecim*, Bâle, 1560, in 16to; 6. *Poematum veterum ecclesiasticorum opera Christiana et operum reliquiæ ac fragmenta*, 1562, in 4to; 7. *De Re Poëtica libri septem*, 1566, in 8vo; 8. *Rerum Misnicarum libri septem*, 1569, in 4to; 9. *Originum illustrissimæ stirpis Saxonicæ*

Fabricius.

libri septem, 1597, in fol.; 10. *Rerum Germaniæ magnæ et Saxoniæ universæ memorabilium volumina duo*, Leipsic, 1609, in fol.

Fabricius, or *Fabrizio, Jerome*, surnamed *Acquapendente*, from his having been a native of the episcopal city of that name, in Italy, where he was born in 1537. His parents, though poor, were desirous to give their son an excellent education, and with this view sent him to Padua, where the young Fabricius soon found powerful protectors to assist in the cultivation of his talents. After completing his course of philosophy, he applied himself to medicine, which he studied under the celebrated Fallopius, and soon became the most distinguished pupil of that learned professor, whom he afterwards succeeded. Fallopius having died in 1562, Fabricius, then only twenty-five years of age, was at first employed merely to give anatomical demonstrations; but he discharged this duty with so much zeal and ability that, in 1565, he was formally promoted to the chair of surgery, whilst that of anatomy, which had hitherto been considered as merely a dependence or accessory of the other, was declared primary in favour of Fabricius, to whom were also assigned very considerable appointments. And to these preferments the senators of Venice added the highest distinctions which it was in their power to bestow. They granted him privileges not less extraordinary than flattering, gave him precedence of the professors of philosophy, named him citizen of Padua, honoured him with a statue and a gold chain, decorated him with the order of knight of St Mark, constructed a superb anatomical theatre for his accommodation, and assigned him a liberal retired allowance, with the right of naming his successor. Fabricius practised his profession with much dignity and with rare disinterestedness. Persons of high rank, who were indebted to him for the re-establishment of their health, made up by rich presents for the fees which the generous physician refused; and these Fabricius collected in a cabinet, on the door of which he caused to be inscribed the words *Lucri neglecti lucrum*. He possessed a beautiful country-house, situated on the delightful banks of the Brenta, and still known by the name of *Montagnuola d'Acquapendente*, where, sound in body and mind, loaded with riches, generally esteemed, and enjoying a brilliant reputation, he calculated on spending a happy old age. But his expectations were cruelly disappointed, and his repose was disturbed by envy and ingratitude. It is even said that he was sometimes obliged to employ the knife for other purposes than surgical operations and dissections. Relations on whom he had never ceased to lavish favours, unworthily betrayed his confidence, and are suspected, not without reason, of having abridged his days by means of poison. Having attained the age of eighty-two, he died suddenly in an agony of vomiting, on the 21st May 1619, leaving to his niece a fortune of two hundred thousand ducats, and to the republic of letters the following works, which are much esteemed: 1. *De Visione, Voce, Auditu*, Venice, 1600, in fol.; 2. *De formato Fœtu liber*, Venice, 1600, in fol.; 3. *De Venarum ostiolis*, Padua, 1603, in fol.; 4. *De Locutione et ejus instrumentis*, Venice, 1603, in 4to; 5. *De Brutorum loquela*, Padua, 1603, in fol.; 6. *De Musculi artificio ac Ossium dearticulationibus*, Vicenza, 1614, in 4to; 7. *De Motu locali Animalium secundum totum*, Padua, 1618, in 4to; 8. *De Respiratione et ejus Instrumentis libri duo*, Padua, 1615, in 4to; 9. *De Gula, Ventriculo, Intestinis*, Padua, 1618, in 4to; and also, *De totius Animalis integumentis*, Padua, 1618, in 4to. These different fragments were collected and printed by Bohn, with a preface, under the title of *Opera omnia Anatomica et Physiologica, hactenus variis locis ac formis edita, nunc vero certo ordine digesta, et in unum volumen redacta*, Leipsic, 1687, in fol. But the Leyden edition, published in 1738, by Bernard-Lifroy Albinus, is preferred to that of Bohn, as containing a life of the author, and the prefaces of the different treatises, which Bohn had unaccountably suppressed. All the writings of Fabricius are truly classical, and fully justify the high reputation of their author. His style is pure, and even elegant; the language of Hippocrates was as familiar to him as that of Celsus; and lucid order pervades all his writings. In regularity of plan and clear luminous method he is unsurpassed. "On a reproché à ce grand chirurgien trop de timidité dans l'exercice de son art, et pourtant nous le voyons," says his French biographer, "pratiquer et perfectionner le trépan, employer avec autant de hardiesse que de talent le bistouri, l'aiguille, le trois-quarts, la rugine et même le fer rouge, quoiqu' en dise Severino. Haller, qui, certes, ne le juge pas avec bienveillance, est forcé de lui rendre justice sur ces divers points." In a word, Fabricius was one of the greatest ornaments of the university of Padua, and one of the most celebrated anatomists and surgeons of the sixteenth century. (A.)

Fabricius, *John Albert*, one of the most learned, laborious, and useful of bibliographers, was born at Leipsic on the 11th of November 1668. He lost his mother in 1674, and five years afterwards his father, Werner Fabricius, director of music in the church of St Paul at Leipsic, and author of several works, particularly *Deliciæ Harmonicæ*, published in 1657. The subject of this notice commenced his studies under his father, who, on his deathbed, recommended him to the care of Valentine Alberti. He studied during five years under Wencelaz Buhl, then for some time under J. S. Herrichen; and, in 1684, he was sent to Quedlinburg, there to continue his studies under Samuel Schmidt. From this period the *Adversaria* of Barthius formed his delight; and when, in 1687, he saw the first volume of Morhof's *Polyhistor*, the desire which he had already felt of devoting himself to letters greatly increased. Having returned to Leipsic in 1686, he was the same year admitted bachelor in philosophy, and, in the beginning of 1688, he took the degree of master in the same faculty; soon after which he published his first work, consisting of only one sheet in quarto. He then applied himself to the study of medicine, which, however, he relinquished for that of theology; and having gone to Hamburg in 1693, he proposed to travel into several countries, when the unexpected and not very agreeable information which now reached him, that the expense of his education had absorbed his whole patrimony, and even left him in debt to his trustee, forced him to abandon his project. He therefore remained at Hamburg, where J. F. Mayer employed him in the capacity of librarian. In 1696 he accompanied his patron to Sweden, and, on his return to Hamburg, not long afterwards, he competed for the chair of logic and philosophy. The suffrages being equally divided between Fabricius and Sebastian Edzardi, one of his opponents, recourse was had to chance, which decided in favour of Edzardi; but in 1699 Fabricius succeeded Vincent Placcius in the chair of eloquence and practical philosophy, after which he took the degree of doctor in theology at Kiel. From 1692 to 1697 he had preached regularly every Friday; but after he received his appointment of professor, he devoted the greater part of his time to the duties of that office. In 1701, J. F. Mayer having established himself at Greifswald, caused the chair of theology in that city to be offered to Fabricius, who, however, refused it on account of his health. But in 1708 he had accepted the situation of professor of theology, logic, and metaphysics, and was preparing to enter on his new office, when the senate of Hamburg induced him to remain, by adding to his charge as professor that of rector of the school of St John, then held by his father-in-law, Schultz, whom Fabricius was very willing to assist in the discharge of his duties. Schultz died in 1709, but Fabricius retained the rectorship two years longer. In 1719 the landgrave of Hesse Cassel made him so advantageous an offer, that Fabricius was on the point of accepting it; but this time also the magistrates, by a seasonable increase of salary, prevailed on him to remain amongst them. An attempt was subsequently made to draw him to Wittenberg. But Fabricius refused to listen to the proposals which were made to him, and died at Hamburg on the 30th of April 1736. Besides the time which he had devoted to the duties of his office, Fabricius spent a considerable portion in maintaining an extensive correspondence, and in receiving the visits of foreigners; but he was so laborious that he was nevertheless the author of a great number of works, the list of which, according to Niceron and Reimar, includes as many as a hundred and twenty-eight. It will be sufficient here, however, to indicate the most remarkable of these, which are, 1. *Scriptorum recentium Decas*, Hamburg, 1688, in 4to; 2. *Decas Decadum, sive Plagiariorum et Pseudonymorum centuria*, 1689, in 4to; 3. *Bibliotheca Latina, sive notitia Auctorum veterum Latinorum quorumcunque scripta ad nos pervenerunt*, Hamburg, 1697, in 8vo, a work which was republished in an improved and amended form by J. A. Ernesti, Leipsic, 1773, in 3 vols. 8vo; 4. *Bibliotheca Græca, sive notitia Scriptorum veterum Græcorum quorumcunque monumenta integra aut fragmenta edita extant, tum plerorumque e manuscript. ac deperditis*, Hamburg, 1705–1728, in 14 vols. 4to, a work which has justly been denominated *maximus antiquæ eruditionis thesaurus*; 5. *Centuria Fabriciorum scriptis clarorum qui jam diem suum obierunt*, 1705, in 8vo, and a second Century in 1727; 6. *Bibliotheca Antiquaria, sive Introductio in notitiam Scriptorum qui antiquitates Hebraicas, Græcas, Romanas, et Christianas scriptis illustrarunt*, 1713 and 1726, in 4to; 7. *Centifolium Lutheranum, sive notitia literaria Scriptorum omnis generis de B. D. Luthero*, 1728 and 1730, in 8vo; 8. *Conspectus Thesauri Litterarii in Italia, præmissam habens præter alia notitiam Diariorum Italiæ litterariorum thesaurorumque ac corporum historicorum et academiarum*, 1730, in 8vo; 9. *Delectus argumentorum et syllabus Scriptorum qui veritatem religionis Christianæ adversus atheos, epicureos, deistas seu naturalistas, idolatras, Judæos et Muhammedanos lucubrationibus suis asseruerunt*, 1721, in 4to; 10. *Salutaris lux Evangelii toti orbi per divinam gratiam exoriens, sive notitia historico-chronologica, litteraria ac geographica propagatorum per orbem totum Christianorum sacrorum*, 1731, in 4to; 11. *Hydrotheology*, in German, 1734, in 4to; 12. *Bibliotheca Latina mediæ et infimæ Latinitatis*, 1734–1756, in 5 vols. 8vo. The principal works edited by Fabricius were, 1. *Vincentii Placcii theatrum anonymorum et pseudonymorum*, Hamburg, in two vols. fol.; 2. *Joannis Mabillonii iter Germanicum, et Joannis Launoii de Scholis celebribus a Carolo Magno et post Carolum Magnum in occidente instauratis liber*, 1717, in 8vo; 3. *Anselmi Bandurii Bibliotheca Nummaria*, 1719, in 4to; 4. *Danielis Georgii Morhofii Polyhistor litterarius, philosophicus, ac practicus, cum accessionibus Joannis Frikii et Joannis Molleri*, 1732, in two vols. 4to; 5. *Bibliotheca Ecclesiastica*, 1718, in fol.; 6. *Codex apocryphus Novi Testamenti collectus, castigatus, testimoniisque, censuris et animadversionibus illustratus*, 1703, in two vols. 8vo; 7. *Codex pseudepigraphus Veteris Testamenti collectus, castigatus, testimoniisque, censuris et animadversionibus illustratus*, 1713 and 1722, in two vols. 8vo.

Fabricius, *Vincent*, born at Hamburg on the 13th of September 1612, studied at Leyden, and there took his degrees in medicine in 1634. He had already made himself known by his talent for Latin poetry; and two years before this, had published a collection of verses, at the solicitation of his friend and patron Daniel Heinsius. He then applied himself to the study of law, in which his progress was not less rapid than it had been in the other sciences, and in due time he became a learned civilian. The bishop of Lubec conferred on him the title of counsellor, with suitable appointments; but he did not hold this situation for any length of time; and having established himself with his family at Dantzic, he was soon afterwards named syndic, and then burgomaster, of that city. The knowledge which he had acquired of the interests of the republic, and the talent for public speaking which he displayed upon occasions of importance, caused him to be thirteen times returned by the senate as their deputy to the Polish diet. He died at Warsaw, during one of the sessions of that body, on the 11th September 1667. The first edition of the poems of Fabricius appeared at Leyden in 1632; and the second, corrected and augmented by the author, in 1638. But his son, Frederic Fabricius, published a third at Leipsic, 1685, in 8vo, containing several pieces which had been omitted in the preceding editions, besides the *Harangues* pronounced by him in the Polish diet, a discourse *De Obsidione et Liberatione urbis Leidensis*, delivered at Leyden in 1632, and the medical theses maintained by him in the same city.

Fabricius, *John-Christian*, the most celebrated entomologist of the eighteenth century, was born at Tundern, in the duchy of Sleswick, in 1742. After having completed his studies, at the age of twenty, he repaired to the university of Upsal, to attend the prelections of Linnæus. How long he remained there is uncertain. But no pupil was ever more indebted to the lessons of his master than Fabricius. All his works on entomology, which have secured to him a well-merited reputation, indicate the precepts, the method, and even the forms of Linnæus, applied to the development of a single new idea, not more fortunate in conception than fruitful in its consequences. Far from disguising the obligations which he owed to his master, Fabricius delighted to expatiate on the happy moments which he had passed in the society of Linnæus; and the grateful scholar has transmitted to us those biographical details, which are not only the most interesting in themselves, but at the same time best fitted to give us an insight into the character of the great naturalist. It was in studying under the latter that Fabricius conceived the idea of his system, and formed the project of his labours on insects. The first insect's mouth which he dissected was that of a cockchafer (*scarabæus stridulus*); he showed it to Linnæus, with the description he had made of it, and proposed to him to employ the organs of the mouth, in order to establish the characters of insects, in the new edition of the *Systema Naturæ* which Linnæus was then preparing. The latter encouraged his pupil to pursue this course, but refused to enter on it himself, because, as he said, he was too old to change his method. Forced to choose a profession, Fabricius studied medicine, and at the age of twenty-five took the degree of doctor in physic; but being soon afterwards appointed professor of natural history in the university of Kiel, he devoted himself entirely to his favourite pursuits, and, in 1775, published his system of entomology. This work gave a new aspect to the science. Swammerdam and Ray had classed insects according to their metamorphoses; Lister, Linnæus, and Geoffroy, according to the organs of motion; and some entomologists, as Reaumur, Scopoli, and even Linnæus himself, had employed the nutritive organs in order to characterize distinctively certain genera. But before the time of Fabricius no one had thought of making these the basis of a general classification. This idea was at once new and bold, and the author evolved it with singular ability. In a second work, which he published two years afterwards, he developed the characters of the classes and genera, showing in the preface the advantages of his method, and, at the same time, excusing its inconveniences. Lastly, in 1778, he published *Entomological Philosophy*, in imitation of the *Botanical Philosophy* of Linnæus; and from this period till his death, that is, during the space of more than thirty years, he was incessantly occupied in extending his system, which he reproduced under different forms in the various works which, from time to time, he gave to the world. But in proportion as the number of species increased, the characters of the *genera*, and even of the classes, became more and more uncertain and arbitrary; and, with reference to this fundamental point, his later writings are perhaps inferior to those which preceded them. The basis which he had assumed was excellent; but it could only conduct him to a *natural method*, not, as he supposed, to a *system;* and this misconception led him to neglect other considerations which would have furnished more exact means of classification. Fabricius had a very extensive knowledge of botany, and of the other branches of natural history. He had been appointed counsellor of state to the king of Denmark, and professor of rural and political economy, in which capacity he published, in German and in Danish, several useful works, though much less celebrated than those which appeared from his pen on the subject of entomology. Fabricius died in 1807, at the age of sixty-five, of a melancholic affection, produced, as is alleged, by the bombardment of Copenhagen. The following is a list of his works: 1. *Systema Entomologiæ*, Flensburg, 1775, in 8vo; 2. *Genera Insectorum*, Kiel, 1776, in 8vo; 3. *Philosophia Entomologica*, Hamburg, 1778, in 8vo; 4. *Species Insectorum*, ibid. 1778, in two vols. 8vo; 5. *Mantissa Insectorum*, Copenhagen, 1787, in 2 vols. 8vo; 6. *Nova Insectorum Genera*, in Mem. of the Soc. of Nat. Hist. Copenhagen; 7. *Entomologia Systematica*, Copenhagen, 1792–1796, in 7 vols. 8vo; 8. *Snpplementum Entomologiæ Systematicæ*, ibid. 1798, in 8vo; 9. *Systema Eleutheratorum*, Kiel, 1801, in 2 vols. 8vo, with an index; 10. *Systema Rhyngotorum*, Brunswick, 1803, in 8vo; 11. *Systema Piezatorum*, ibid. 1804, in 8vo; 12. *Systema Antliatorum*, ibid. 1805, in 8vo; 13. Description of the *Tipnla Sericea* in the Berlin Mem. tome v.; 14. *De Systematibus Entomologicis*, in the same collection; 15. *Considérations sur l'ordre général de la Nature*, Hamburg, 1781, in 8vo; 16. *Traité de la Culture des Plantes à l'usage des cultivateurs;* 17. *Observations sur l'engourdissement des Animaux durant l'hiver*, inserted in the *Mag. de Physique*, tom. ix. p. 79; 18. *Résultat des Leçons sur l'Histoire Naturelle*, Kiel, 1804, in 8vo; 19. *Sur l'accroissement de la Population, particulièrement en Danemark;* 20. *Eléments d'Economie Politique a l'usage des étudiants*, Flensburg, 1775, in 8vo; 21. *Renseignements Historiques sur le Commerce du Danemark;* 22. *Hvori bestaaer Borgendyd besvaret;* In what consists civic virtue? Copenhagen, 1786, in 8vo; 23. *Sur les Finances et la Dette en Danemark;* 24. *Recueil d'Ecrits sur l'Administration*, Kiel, 1786 and 1790, in 2 vols. 8vo; 25. *Sur les Académies, particulièrement en Danemark*, Copenhagen, 1796, in 8vo; 26. *Voyage en Norwège*, Hamburg, 1799, in 8vo; 27. *Lettres sur Londres*, Leipsic, 1784, in 8vo; 28. *Lettres au sujet d'un voyage fait en Russie;* 29. *Remarques Minéralogiques et Technologiques;* 30. *Remarques sur le Danemark*, written in English, and published by Pinkerton in his *Modern Geography*, 1807.

FABROT, Charles-Annibal, one of the most celebrated jurisconsults of his time, was born in 1580, at Aix in Provence, whither his father, originally of Nismes, had gone to establish himself during the civil wars. His early studies were successfully prosecuted, and he made great progress in the ancient languages and in the civil and the canon law. In 1606 he took the degree of doctor, and was soon afterwards admitted as advocate before the parliament of Aix. As this court then reckoned amongst its members men of distinguished merit, such as the celebrated Peiresc and William Duvair, who was its first president, their common taste for letters naturally united them with Fabrot, for whom, in 1609, Duvair procured a professorship in the university of Aix. Having become keeper of the seals, the latter carried his young friend with him to Paris, where Fabrot remained until after the death of his benefactor, when he returned to resume his peaceful functions as professor. But these did not absorb the whole of his time, and he employed his leisure in other labours, which, however, had all a relation to jurisprudence. The great interpreters whom the sixteenth century produced had left almost nothing to be added in regard to the books of this science written in Latin. But Fabrot opened for himself a different path. The successors of Justinian on the throne of Constantinople had caused to be executed in Greek an abridgment of his compilations, to which were added articles taken from the fathers and the councils; and to this abridgment Leo the Philosopher gave the name of *Basilica*, which, in fact, formed the code of the eastern empire until its destruction. The *Basilica*, long unknown, were in some sort discovered by Cujas, who made great use of them in his writings, but did not publish them. Fabrot, however, undertook this task, and, about 1639, extracted from this collection, and published in Greek and Latin, fourteen laws, which are wanting in the Digest. These, with some other productions of Fabrot, were inserted by Everard Otton in his *Thesaurus Juris Civilis*. Of the sixty books of which the *Basilica* were composed, thirteen have been lost. Those which remain Fabrot translated; and he supplied, by means of summaries, the place of those which are lost. This work, consisting of seven volumes in folio, was published in 1647 at Paris, where Fabrot had now established himself, and was dedicated to the Chancellor Seguier, through whose influence, exerted in his favour, he obtained a considerable pension, by means of which he was enabled to continue his useful labours. Matthieu Molé, at first procureur-général, then first president and keeper of the seals, a man whose heroic firmness is so well known, and Jerome Bignon, a magistrate distinguished for his knowledge and integrity, likewise gave Fabrot proofs of the estimation in which they held his talents. Besides the *Basilica*, the latter also translated into Latin the Greek paraphrase which Theophilus had made of the *Institutions* of Justinian (Paris, 1638 and 1657, in 4to). The particular nature of his pursuits having rendered him familiar with the Byzantine historians, Fabrot published several of their works, such as those of Cedrenus, Nicetas, Anastasius the Librarian, and others, enriched with notes and dissertations. And as he was not only acquainted with the civil, but also with the canon law of the lower empire, which in fact form but one whole; when Justel and William Voet compiled their Library of Canon Law, which appeared in 1661, they inserted in that compilation the constitutions of Theodorus Balsamon, which were found amongst the papers of Fabrot, with notes in his peculiar manner. But one of the undertakings which have done the greatest honour to this learned jurisconsult, is his edition of the works of Cujas, which he corrected according to several manuscripts, and enriched with notes and several treatises of Cujas, which had not previously seen the light. Before the appearance of those of Naples and of Venice, this was the best of all the editions of Cujas. Fabrot commenced it in 1652, and completed it in 1658. It is believed that the continued and intense application which he bestowed on this work caused the malady of which he died on the 16th of January 1659. His reputation was so extensive, that the most celebrated universities of France desired to have the benefit of his services as professor of law; but he refused every offer of the kind which was made to him, however advantageous, that his attention might not be diverted from the great undertakings in which he had embarked. Fabrot wrote, 1. *Epistola de Mutuo cum responsione Cl. Salmasii ad Menagium*, Leyden, 1645, in 8vo; 2. *Les Antiquités de la Ville de Marseille*, translated from the Latin of J. Raymond de Solier, Marseilles, 1615, and Lyons, 1632, in 8vo; 3. *Exercitationes duæ de tempore partûs humani et de numero puerperii*, Aix, 1629, in 4to; 4. *Prælectio in titulum Decretalium "De vita et honestate Clericorum,"* Paris, 1651, in 4to; 5. *Notæ at titulum Codicis Theodosiani "De paganis sacrificiis et templis,"* Paris, 1648, in 4to.

FABULOUS, something consisting of or connected with fable.

FACATA, or Fucata, a seaport of Japan, in the island of Ximo, where the Jesuits formerly had a considerable establishment and a church. It is twenty-seven miles west-north-west of Taisero.

FACE, the surface or first side which a body presents to the eye. Thus, we say, the *face* of the earth, of the waters, and the like; polyhedrons have several *faces;* a die or cube has six *faces.*

Face is particularly used for the visage of an animal, especially of man, and comprehends, in the latter, all that part of the head which is not covered with long hair. The Latins call it *facies, vultus, os.*

FACIES Hippocratica, in *Medicine*, is when the nostrils are sharp, the eyes hollow, the temples low, the tips of the ears contracted and cold, the forehead dry and wrinkled, and the complexion pale or livid. The Hippocratic face is chiefly observed towards the close of phthisis pulmonalis, and other consumptions, and is held as a sure prognostic of death. If it appear within three days after the attack of an acute disease, it is deemed a fatal symptom.

FACTION, a cabal or party formed in a state, city, or company.

Faction, in *Antiquity*, a name given to the different companies of combatants in the circus. They were four in all; the white, the red, the green, and the blue, to which Domitian added another of purple colour. They were so denominated from the colour of the liveries they wore, and were dedicated to the four seasons of the year; the green being consecrated to spring, the blue to winter, the red to summer, and the white to autumn. It appears from ancient inscriptions, that each faction had its procurators and physician; and that party rage ran so high amongst them, that in a dissension between two factions, in the time of Justinian, nearly forty thousand men lost their lives.

FACTITIOUS, any thing made by art, in opposition to that which is the production of nature. Thus, factitious cinnabar is opposed to native cinnabar.

FACTOR, in *Commerce*, is an agent employed by merchants residing at other places, to buy or sell goods, negotiate bills, or transact any kind of business on their account, and entitled to a certain allowance for his trouble.

A supercargo differs from a factor in this, that the business of the former is limited to the care of a particular cargo; he goes along with it, and generally returns when his business is completed; whereas the latter has a fixed residence abroad, and executes business for different merchants.

Factor, in *Multiplication*, a name given to the multiplier and multiplicand, because they constitute the product.

FACTORAGE, called also *commission*, is the allowance given to factors by the merchant who employs them.

FACTORY is a place where a considerable number of factors reside, in order to negotiate for their masters or employers.

FACULÆ, in *Astronomy*, certain bright and shining parts, which the modern astronomers have, by means of telescopes, observed on the surface or disc of the sun. The word is Latin, being a diminutive of *fax*, a torch, and supposed, in this case, to be applied from these spots appearing and disappearing by turns.

FACULTY, in *Law*, a privilege granted to a person, by favour and indulgence, of doing that which by law he ought not to do.

Faculty, in the schools, a term applied to the different members of an university, divided according to the arts and sciences taught there. Thus, in most universities there are four faculties; that of arts, which includes humanity and philosophy; that of theology; that of medicine; and that of law.

FAENZA, a city of Italy, in the delegation of Ravenna, in the papal dominions. It is situated on a plain watered by the river Lamona, from which a canal is formed to join the Po Primero. It contains, besides a cathedral, twenty-eight churches, eight monasteries, and eight nunneries, with 14,000 inhabitants, who are employed in silk and other manufactures. At this place the invention of porcelain was introduced; and hence, in most of the languages of Europe, that commodity has obtained the name of the city. It was the birth-place of the celebrated Torricelli, the disciple of Galileo. Long. 11. 36. E. Lat. 44. 21. N.

FAERNUS, Gabriel, a celebrated modern Latin poet, was a native of Cremona, and flourished during the sixteenth century. He was so eminently skilled in all parts of polite literature, that the Cardinal de' Medicis, afterwards Pope Pius IV. held him in high estimation. He was the author of some Latin elegies, of a hundred Latin fables in iambic verse, selected from the ancients, and of several pieces of criticism. He was also remarkably dexterous in deciphering manuscripts, and in restoring ancient authors; and he took such pains with Terence, that Bentley has adopted all his notes in the edition which he published of that dramatist. Faernus died at Rome in 1561; and De Thou, who wrote his eulogy, says that the learned world was greatly indebted to him, and would have been still more so, if, instead of suppressing the then unknown fables of Phædrus, from fear of lessening the value of his own Latin fables, written in imitation of Æsop, he had been content with imitating them. Perrault, however, who translated the fables of Faernus into French, has defended him from this imputation, by showing that the first manuscript of Phædrus's fables, found in the dust of an old library, was not discovered till about thirty years after the death of Faernus. In fact, Plautus and Terence were his models; and the merit of his elegant style is enhanced by the circumstance that he was not an imitator of Phædrus, whom it has been satisfactorily shown he did not know. His fables, immediately upon their appearance, obtained universal applause, and were reprinted at Cologne, at Antwerp, and at Brussels. Faernus also wrote, 1. Two *Books of Corrections* on the philippics and three other speeches of Cicero, from a manuscript which had been discovered in the Vatican Library, and which he regarded as the most ancient of all those that existed of the works of Cicero; and, 2. *Notes* on Catullus and Plautus, and a *Commentary* on Terence, which was printed by

Pietro Vettori, Florence, 1567, in 8vo, and reprinted at Paris, 1602, in 4to.

FAGGOT, in the times of persecution, was a badge worn on the sleeve of the upper garment, by such persons as had recanted or abjured what was then termed heresy. It was put on after the person had carried a faggot, by way of penance, to some appointed place of solemnity. Leaving off wearing this badge was sometimes interpreted as a sign of apostasy.

FAGGOTS, amongst military men, persons hired by officers, whose companies were not full, to muster and conceal the deficiencies of such companies. This disgraceful practice has long ceased in our army.

FAID, or FEID, a town of Arabia, in the province of Nedsjed, 140 miles north-east of Hagiar. Long. 40. 36. E. Lat. 26. 54. N.

FAIFO, or HAIFO, a town of Cochin-China, situated about ten miles from the sea, on a navigable river, which flows into the bay of Huron. It was at one time a place of some importance, the streets being regular, and the houses built of brick. But it was destroyed in the course of the revolutions which befel the country; and its prosperity is now only reviving. Long. 108. 10. E. Lat. 15. 50. N.

FAILSWORTH, a township of the county of Lancaster, within the parish of Manchester, inhabited chiefly by manufacturers of cotton goods, whose numbers amounted in 1801 to 2622, in 1811 to 2875, in 1821 to 3358, and in 1831 to 3667.

FAINT ACTION, in *Law*, a feigned action, or such as, although the words of the writ are true, yet, for certain causes, the plaintiff has no title to recover thereby.

FAIRS AND MARKETS. The intimate alliance which subsists between these institutions renders it as necessary as it is convenient to treat of them together. As the term is now generally understood, a fair is just a greater species of market, but the periodical recurrence is less frequent. Both are appropriated to the sale of one or more kinds of goods, the hiring of servants, labourers, &c. In most cases, however, fairs are more numerously attended than markets, and are generally characterized by various exhibitions got up for the amusement of the people.

The following account of the origin of fairs is given by Mr M'Culloch, in his *Dictionary of Commerce.* "Institutions of this sort are peculiarly serviceable in the earlier stages of society, and in rude and inland countries. The number of shops, and the commodities in them, are then either comparatively limited, or they are but little frequented by dealers; so that it is for the advantage of all that fairs should be established, and merchants induced to attend them. For this purpose various privileges have been annexed to fairs, and numerous facilities afforded to the disposal of property in them. To give them a greater degree of solemnity, they were originally, both in the ancient and modern world, associated with religious festivals. In most places, indeed, they are still held on the same day with the wake or feast of the saint to whom the church is dedicated; and, till the practice was prohibited, it was customary, in England, to hold them in churchyards. (*Jacob's Law Dict.* art. *Fair.*) But since the growth of towns, and the opportunities afforded for the disposal and purchase of all sorts of produce at the weekly or monthly markets held in them, the utility of fairs, in this country at least, has very much diminished; they have also lost much of their ancient splendour; and, though some of them are still well attended, and of real use, a good number might be advantageously suppressed.

"But it is far otherwise in inland countries, where the facilities for carrying on commercial transactions are comparatively circumscribed. There it is of the utmost importance, that certain convenient places and specified periods should be appointed for the bringing together of commodities and dealers. This is not only the readiest and best means of promoting commerce, but also of softening national antipathies, and diffusing a knowledge of the products, arts, and customs of other countries."

In England the right of holding a fair must be derived from the crown, and, in the grant obtained, provision is made that no other fair shall be injured by the one to be established. The times of holding the fairs are determined by the letters-patent appointing the fair or market, or by usage; and penalties are imposed if they are held beyond the time specified. A *bona fide* sale made in a fair or open market, in general transfers the complete property of the thing sold to the vender, so that, however vicious or illegal the title of the vender may be, the vendee's is good against every one except the king. But the sale, in order to come within this rule, must be made on the market day, and at the place assigned for the market. Formerly the mayor or steward presided at a court called the court of *pié poudre*, in allusion to the dusty feet of the suitors, where questions as to contracts, &c. were decided; but these courts are now entirely set aside. Still, as of old, however, there is a clerk appointed, whose duty it is to see that every thing is sold according to just weights and measures. There is generally a toll attached to fairs and markets, which is paid by the buyer after the thing brought to the market has been sold.

British Fairs. Amongst these may be specified that of Stourbridge, in Worcestershire. Bristol has two considerable fairs, one in March and one in September. Exeter December fair is for cattle, horses, and most sorts of commodities. Weyhill fair, in Hampshire (October 10), has probably the greatest display of sheep of any fair in the kingdom. Bartholomew fair, in London, used to be of considerable importance, but is now appropriated only to shows of wild beasts, and such like exhibitions, and might be suppressed with advantage. St Faith's, near Norwich (October 17), is the principal English fair for Scotch cattle. They are sold to the graziers and feeders of Norfolk, Suffolk, Essex, and other counties, by whom they are fattened for the London markets, where they are met with in great abundance. But besides those sold at St Faith's, large numbers of Scotch cattle are disposed of at Market Harborough, Carlisle, Ormskirk, and other places. Ipswich has two considerable fairs; one in August, for lambs, and one in September, for butter and cheese; and it is reckoned that above 100,000 lambs are annually sold at the former. Woodborough-hill, in Dorset, is for west-country manufactures, as kerseys, druggets, &c.; and Woodstock October fair, for cheese. Northampton and Nottingham have each several large fairs, for horses, cattle, cheese, &c. The August fair of Horncastle, in Lincolnshire, is the largest horse fair in the kingdom, many thousand horses being exhibited for sale during its continuance; and it is resorted to by crowds of dealers from all parts of Great Britain, by several from the Continent, and sometimes even from North America. Howden, in Yorkshire, has also a very large horse fair, particularly for Yorkshire hunters. Devizes, in Wiltshire, has several large fairs for sheep and cattle. There is usually a large display of cheese at the Gloucester April fair. A guild, or jubilee, commencing the last week of August, is held every twentieth year at Preston, in Lancashire; the last was held in 1822, and was well attended. The October fair of Market Harborough, Leicestershire, lasts nine days, and a great deal of business is usually done in cattle, cheese, &c. Woodbridge Lady-day fair is celebrated for the show of Suffolk horses. Falkirk fair, or tryst, is one of the most important in Scotland, for the sale of cattle and sheep. The October fair of Ballinasloe, in the county of Galway, is famous for the display of cattle and sheep;

and by far the largest proportion of these animals raised for sale in Connaught being disposed of at it.

French Fairs. The principal French fairs are those of St Germains, Lyons, Rheims, Chartres, Rouen, Bordeaux, Troyes, Bayonne, and Beaucaire, but they are said to be for the most part much fallen off, although that which was held in 1833, at the last-named place, was the greatest which had taken place for many years.

German Fairs. The principal German, or rather European fairs, are those of Frankfort on the Maine, Frankfort on the Oder, and Leipsic. The business transacted at these fairs is in general very great. Merchants of all nations are there assembled, for disposing of the manufactures, merchandise, and productions, for which their several countries are distinguished. Frankfort on the Maine has two, and Frankfort on the Oder three fairs yearly. Leipsic has also three annual fairs, and these are by far the most celebrated. They are held on the first of January, at Easter, and at Michaelmas. The first is the least important. The two latter, particularly the former, are remarkable for the vast number of new publications usually offered for sale. They are attended by all the principal booksellers of Germany, and by many from the adjoining countries, who adjust their accounts, learn the state of the trade in all parts of the world, and endeavour to form new connections. Most German publishers have agents in Leipsic, which is to the literature of Germany what London is to that of Great Britain. As many as four thousand new publications have been in a single Leipsic catalogue. The fairs ought to close in eight days, but they usually continue for about three weeks.

Italian Fairs. Of these, the most celebrated is that of Sinigaglia, on the Misa. It commences on the 14th of July, and continues for about twenty days. Here, as at the German fairs, are assembled merchants from almost all nations.

Russian Fairs. These are numerous, and many of them are well attended. The most important is held at Nishnei-Novogorod, a city situated at the confluence of the Oka with the Wolga. It is the great emporium of the internal trade of Russia. The fair generally lasts from six weeks to two months, and is well known all over the east of Europe. In point of value this fair is considered as second to none in Europe. Another celebrated Russian fair is that of Kiachta, on the Chinese frontier. At this fair by far the largest part of the commerce between the Russian and Chinese empires is transacted. The goods disposed of are principally the products of the respective countries.

Eastern Fairs. The most important fair in the eastern world is that held at Mecca, during the resort of pilgrims in the month of Dhalhajja. It has declined of late years, but the concourse which attends it is still very great. The greatest fair in India is that held at Hurdwar in Hindustan. The town, although inconsiderable, is famous for being one of the principal places of Hindu pilgrimage, which takes place along with the fair at the vernal equinox.

The fairs of Portobello, Vera Cruz, and Acapulco, once so famous, are now totally deserted; and that of the Havannah is also much fallen off.

Fair, in nautical language, is used for the disposition of the wind, when it is favourable to a ship's course, in opposition to that which is contrary or foul. The term *fair* is more comprehensive than the term *large*, and includes about sixteen or eighteen points of the compass. *Large* is confined to the beam or quarter, that is, to a wind which crosses the keel at right angles, or obliquely from the stern, but never to one right a-stern.

FAIR ISLE, an island belonging to Zetland, lying between that group of islands and the Orkneys, extending fully three miles in length by about two in breadth, and of an oblong form. It is quite mountainous, with a precipitous and dangerous coast, which is only accessible upon the south-eastern side. It is inhabited; but the soil chiefly affords pasturage for sheep.

FAIRFAX, EDWARD, a poet of considerable note, who flourished in the reigns of Queen Elizabeth and James I. He was the second son of Sir Thomas Fairfax of Denton, in the county of York. The precise date of his birth is uncertain; and it has even been supposed that he was illegitimate; but there does not seem to be any good ground for such a supposition. The family of which he was descended had a strong propensity for the military profession; and his father having passed his youth in the wars of the Continent, was present at the sacking of Rome under Charles Duke of Bourbon, in the year 1527. In 1591 the poet's elder brother, Thomas, who afterwards became the first Lord Fairfax, received the honour of knighthood, before Rouen, on account of the bravery he had displayed whilst serving with the army sent to the assistance of Henry IV.; and the same individual afterwards signalized himself on many occasions in Germany. A younger brother, Charles, also distinguished himself in arms, having been present at the battle of Newport in 1600, and commanded at the famous siege of Ostend, where he received a wound in the face from a splinter of the skull of a marshal of France, who was killed near him by a cannon ball. But whilst his brothers were thus employed in military service abroad, Edward Fairfax devoted himself to the peaceful pursuits of literature at home, and the acquirements he made were such as would have qualified him to fill with credit any employment either in church or state. But an invincible modesty, joined to a love of retirement and a contemplative turn of mind, induced him to prefer the groves and cascades of Denton, and the forest of Knaresborough, to all the advantages of worldly distinction; and, accordingly, having fixed himself as a private gentleman at Fuyistone, he devoted his leisure to composition both in prose and in verse, and to the education of his own and the children of his brother, Lord Fairfax, who are said to have profited much by his instructions. In his book on Dæmonology, Fairfax has given the following character of himself:—"I am in religion," says he, "neither a fantastic puritan nor a superstitious papist, but so settled in conscience, that I have the sure ground of God's word to warrant all I believe, and the commendable ordinances of our English church to approve all I practise; in which course I live a faithful Christian and an obedient subject, and so teach my family." In these principles he persevered until his death, which took place about 1632, at Newhall, in the parish of Fuyistone, between Denton and Knaresborough. Fairfax's first, and indeed his principal work, was his translation of Tasso, which he executed when very young, and dedicated to Queen Elizabeth. The merits of this performance were at one time much overrated; and, latterly, it has been in some measure superseded by the translation of Hoole, which, though not a little stiff and formal, possesses greater equality, and is perhaps also superior in point of accuracy: but it must at the same time be confessed, that the diction of Fairfax is remarkable for its purity, freedom, and elegance; that his numbers are often highly musical; and that he is one of the few writers, if not the only one, down to the time of Sir William Davenant, who does not require an apology to be made for him on account of the age in which he lived. "Fairfax," says Hume, "has translated Tasso with an elegance and ease, and at the same time with an exactness, which for that age are surprising." But the poetical exertions of Fairfax did not terminate with this translation. He also composed eclogues, twelve in number, relative to the manners, the characters, and the incidents of the times; compositions which he seasoned with many fine touches of piquant satire, and dignified with useful lessons both in public and private morality. The fourth in order of these eclogues was printed in the *Muses' Library* in 1737; but it is somewhat surprising that the whole of them should never have been published, and it is not improbable that the manuscripts are now lost. Of the prose writings of Fairfax, most of which related to the controversy with the church of Rome, none has ever appeared in print; and even his treatise on Dæmonology, if yet extant, still remains in manuscript. This last production, which is entitled "A Discourse on Witchcraft, as it was acted in the family of Mr Edward Fairfax of Fuyistone, in the county of York, in 1621," and of which a copy was in the possession of Mr Isaac Reed, would no doubt, if published, throw considerable light on the superstitious opinions and feelings of the age when it was written, and might also perhaps contribute indirectly towards the true exposition of those spectral illusions and phantasms which, while they commanded the unhesitating belief, exercised so powerful an influence over the minds of our forefathers. Fairfax left several children, sons as well as daughters, the eldest of whom, William, a scholar of much the same temper with his father, though rather more cynical, translated Diogenes Laertius from Greek into English.

FAIRFAX, *Thomas Lord*, who acted so conspicuous a part during the civil wars in the reign of Charles I., and at length became general of the parliamentary forces, was the eldest son of Ferdinand Lord Fairfax, by Mary, daughter of Edmund Sheffield, Earl of Mulgrave, and was born at Denton in the parish of Otley, Yorkshire, in the month of January 1611. After the usual school education, he entered St John's College, Cambridge, where he studied some time, and imbibed that love of learning for which he was afterwards distinguished. Being of a martial disposition, he proceeded to Holland, where, in order to improve himself in the art of war, he served as a volunteer under Horatio Lord Vere. On his return to England he married a daughter of that officer, and retired to his paternal mansion at Denton, where he conceived an extreme aversion to the court, either by the instigation of his wife, who was a zealous Presbyterian, or by the persuasion and example of his father, who had become strongly disaffected towards the royal cause. Accordingly, when the king endeavoured to raise a guard for his own person at York, intending it, as the event afterwards proved, to form the nucleus of an army, he was employed by his party to present a petition to his sovereign, entreating him to hearken to the voice of his parliament, and to discontinue the raising of troops; and when Charles attempted to avoid receiving it, Fairfax followed him with the petition, which he presented upon the pommel of his saddle, in Heyworth-moor, before an assemblage of nearly a hundred thousand persons. Shortly afterwards, upon the breaking out of the civil war, his father having received from the parliament a commission appointing him general-in-chief of the forces in the north, Fairfax was at the same time made general of the horse under him. In this war both father and son distinguished themselves by their bravery, intelligence, and activity, particularly at the battle of Marston-Moor and the taking of York; Thomas Fairfax having been twice severely wounded, and having frequently exposed his life in the most daring manner. His exploits, therefore, gained him the confidence of his party; and, in 1645, when it was judged expedient to new-model the army, and to deprive Essex of the command, the parliament, knowing that Fairfax was a zealous Presbyterian, unanimously appointed him as successor to Essex. In this command Cromwell was joined with him in the capacity, and with the title, of lieutenant-general; but the latter only accepted the inferior grade in the hope, and most probably with the intention, of rendering himself really master.

As soon as Fairfax, who was then in the north of England, received the orders of parliament, he repaired to London, where he arrived on the 18th of February 1645, and was presented to the House of Commons on the following day, by four members, and complimented by the speaker, who handed him his commission. He had full powers to name all the generals under his orders; and, in the month of April, he proceeded to Windsor, where he employed himself in organizing the new army which the parliament had just voted. But it was in reality Cromwell who, under the name of Fairfax, constantly acted; for the lieutenant-general had acquired so great an ascendency over his chief, that he did, or caused to be done, whatever he pleased; and having had the address to persuade Fairfax that he had only in view the good of religion and the commonwealth, he thereby disposed the latter to receive his counsels, and to place entire confidence in his character. Being appointed governor of Hull, and sent by parliament to succour Taunton in Somersetshire, then closely besieged by the royalists, Fairfax, at the latter place, to which he had proceeded with all possible diligence, received counter-orders to join Cromwell with the forces under his command, and to watch the motions of the king, who had just quitted Oxford. After various movements, the hostile armies met, on the 14th of June, at Naseby in Northamptonshire, and a battle took place, which ended in the total discomfiture of the royalists. The king was obliged to fly from the field, and retired into the country of Wales. On the 16th the victorious Fairfax laid siege to Leicester, which surrendered two days afterwards. On the 10th July he offered battle to Lord Goring, who had been obliged to raise the siege of Taunton; on the 22d he carried Bridgewater by assault, and thereafter took several other places; and on the 10th September he forced Bristol to capitulate. Having reduced to subjection the whole country to the west of London, he next marched to the south; but finding it impossible, from the rigour of the season, to besiege Exeter, a well fortified city, in regular form, he converted the investment into a blockade, which lasted until the 13th of April 1646. In this interval he took several places, defeated and dispersed different bodies of royalists, and completely humbled, or rather annihilated this party in the provinces of the south and west, which had formed its great stronghold and constituted its principal resource in England. Having obtained these successes, Fairfax marched in all haste to Oxford, where was the most considerable garrison that yet remained to the king. But the latter, afraid of being shut up in the place, and thus falling into the hands of his mortal enemies, withdrew secretly, in disguise, and proceeded to Newark, to throw himself into the arms of the Scotch. Oxford capitulated, and by the end of September Charles had neither army nor garrison in England.

Fairfax having arrived in London on the 12th November, was complimented and thanked for his successes by the two houses of parliament, who repaired to his residence for the purpose. But he had scarcely time to enjoy a little repose from the fatigues of war, when he received a commission to escort the two hundred thousand pounds, granted by the English parliament to the Scotch army, in name of arrears of pay, but, in reality, according to some, as the price of the king's person, which that army had consented to give up. Charles was delivered up to the commissioners of parliament on the 30th January 1646. Fairfax, who preceded the king, having met him beyond Nottingham, dismounted from his horse, kissed the royal hand, and having resumed his seat, discoursed with the unfortunate prince during the journey to Holdenby. That Charles was satisfied with the conduct of Fairfax, appears from the observation which he addressed to one of the parliamentary commissioners. "The general," said he, "is a man of honour, and keeps his word which he had pledged to me;" a remark, the precise import of which, however, is not understood, as the circumstances to which the king evidently alludes have not been stated by any historian. Fairfax was received at Cambridge with the greatest honours, and created master of arts. By this time the parliament, after long debates, had appointed him general of the forces, which were still to be kept on an effective footing; for it was now intended to disband the greater part, and send the remainder to Ireland. But the soldiers being extremely dissatisfied with a project which threatened to deprive them of all the advantages they had reaped from the war, Cromwell, who had hitherto allowed Fairfax to enjoy in appearance the honours of supreme command, resolved, in concert with Ireton, his son-in-law, a man not less crafty than himself, but a better speaker and a more able writer, to profit by this disposition of the army, in order to foment a revolt against the parliament. Accordingly, they circulated a report among the soldiers, that the parliament, having the king in its power, intended to disband the greater part of the army, in order to deprive them of their arrears of pay, and to send the rest into Ireland, to be exterminated by the fierce inhabitants of that island. Inflamed by these rumours, the army, on the suggestion of Ireton, appointed a committee of its own number, to consult for its wellbeing, assist at the councils of war, and watch over the peace and security of the kingdom. Fairfax now observed with regret, that these agitators, as they called themselves, had usurped the power which he should have exercised over the army; he discerned that they were the forerunners of anarchy, and that their design was to raise their own fortune on the ruin of the state. He therefore resolved to resign his commission; but the chiefs of the Independents, whose projects were not fully matured, persuaded him to retain it. He then, with culpable weakness, co-operated in all the proceedings of the army, which had for their object to destroy the power of parliament. In vain did the two houses enjoin him to leave his troops at the distance of at least fifteen miles from London; he entered that city in triumph, with the speaker and sixty members of the House of Commons, who, betraying the privileges of parliament, had retired to the camp, and whom he now re-instated in their places. For this proceeding, which in any view deserved a halter, he was rewarded with the thanks of both houses, and the office of governor of the Tower. But having soon afterwards learned that the king had been removed by violence from Holdenby, Fairfax, indignant at this proceeding, repaired to the place where this unfortunate prince was detained near Cambridge, conducted himself towards the royal captive in the most respectful manner, and caused him to follow all the movements of the army, in order that the parliament might not obtain possession of his person, for which purpose commissioners had already been named by both houses. The credit of Fairfax with the troops, however, diminished daily; he had neither firmness of will nor force of character sufficient to oppose himself to a power which had long overtopped his own; and although he had in view none of the objects which Cromwell cherished, he contributed to render them all successful. It was doubtless in consequence of this inconceivable weakness that he concurred in the manifesto of the army, published in the month of January 1648, which adhered to the vote of the commons, that no more addresses or messages should be presented to the king, and protested that it would obey parliament in every thing which might henceforth be necessary for the government of the kingdom and the safety of parliament, whether with the king or against him.

At this period Fairfax lost his father, whom he succeeded in his titles and employments; but still he remained, as before, the docile instrument of the ambition of Cromwell. He displayed the greatest activity in putting down insurrections, and took Colchester, whither the remains of the royalist party had betaken themselves. At the end of the year he returned to London, in order to keep in check that city and the parliament; and he took up his head-quarters in the palace of Whitehall. Here, being struck with a sort of moral stupefaction, which prevented him from reflecting on the character or tendency of his own actions, all his proceedings served to accelerate the crisis of the king's fate; but although placed at the head of the judges before whom Charles was to be tried, he refused to act, probably at the instigation of his wife, who on this occasion displayed a boldness and intrepidity worthy of all admiration. He even exerted himself to prevent the execution of the sentence, and tried to persuade his regiment to rescue the king from the hands of those who had condemned him to death. But Cromwell and Ireton, ably assisted by Harrison, imposed on the pious credulity of Fairfax; and, whilst these hypocrites kept the imprudent general engaged in prayer, the fatal blow was struck. A few days after the execution of Charles, he was appointed a member of the council, but refused to sign the form of oath by which all that had been done relative to the king and to the royal authority was approved of. Towards the end of March he received the title of general of the troops in England and in Ireland; but he no longer possessed any real power. He marched against the levellers, who having become numerous, had occasioned considerable uneasiness, and would soon have rendered themselves formidable, and completely routed them at Burford in Oxfordshire. He then repaired to Oxford, where he received the degree of doctor of laws; after which he proceeded to allay the troubles in Hampshire, assembled the army at Guildford, exhorted it to obedience, and returned to London, where he was presented with a basin and ewer of beaten gold. In June 1650, when the Scotch had declared for Charles II., the council of state in England having resolved to send an army to Scotland, in order to prevent an invasion, Fairfax was consulted respecting the design, which he appeared at first to approve; but afterwards, by the persuasion of his lady and the presbyterian ministers, he declared himself satisfied that the parliament of England had no just ground for sending an army to invade Scotland; and, in terms of this declaration, he resigned his commission. The supreme command of the army was then conferred upon Cromwell, who saw with pleasure the retirement of a man who, being no longer necessary to his ambitious projects, now formed an obstacle to their entire accomplishment. The parliament, however, in some measure indemnified Fairfax, by granting him a pension of five thousand pounds sterling.

Being thus released from all public employment, Fairfax retired to Nunappleton, Yorkshire, where he passed his time in tranquillity, earnestly praying, it is said, for the restoration of the royal family, and resolved to seize the first opportunity which offered to contribute towards its accomplishment. Accordingly, when General Monk invited him to assist in the operations about to be undertaken against Lambert's army, he promptly obeyed the call, and on the 3d December 1659 appeared at the head of a body of Yorkshire gentlemen; and such was the influence of his name and reputation, that the Irish brigade, consisting of twelve hundred horse, quitted Lambert's colours and joined him; an event which was speedily followed by the breaking up of all Lambert's forces. On the 1st January 1660 he made himself master of York, and on the 2d he was chosen by the Rump Parliament, one of the council of state, an appointment which was renewed on the 23d of February ensuing. On the 29th of March he was elected one of the knights of the county of York in the healing parliament; and he was put at the head of the commission appointed by the House of Commons, on the 3d of May, to wait upon Charles II. at the Hague, and urge his speedy return. After the dissolution of the healing parliament, which was of short duration, he again retired to his seat in the country, where he lived, in a manner strictly private, till his death, which happened on the 12th of November 1671, in the sixtieth year of his age. In person Lord Fairfax was tall, but of a gloomy and melancholy disposition. He was, however, of a meek and humble demeanour, and of few words in discourse or council; but when his judgment had once been satisfied, he remained unalterable, and frequently acted in opposition to the opinions of his council. His valour was unquestionable, though not of a cool and steady, but rather of a passionate and excited kind; in battle he seemed transported beyond himself, and appeared like one distracted and furious. In a word, Fairfax would have been considered as the greatest of the parliamentary commanders, had not his exploits been eclipsed by the more brilliant achievements of Cromwell; and he would have been thought one of the greatest heroes of the rebellion, if the extreme narrowness of his genius in every thing but war had not disqualified him for shining as a statesman.

Lord Fairfax had some taste for literature, and both at York and at Oxford endeavoured to save the libraries from pillage. He also presented twenty-nine ancient manuscripts to the Bodleian library, including a beautiful one of Gower's *Confessio Amantis.* Lord Orford has introduced him not only as an historian, but as a poet, among his royal and noble authors; and in Thoresby's Museum the following pieces were preserved in manuscript, viz. 1. the Psalms of David; 2. the Song of Solomon; 3. the Canticles; 4. Songs of Moses, and other parts of Scripture, versified; 5. a Poem on Solitude; 6. Notes of Sermons; and 7. a Treatise on the Shortness of Life. But of all his productions, the most curious was a copy of verses written on the horse which Charles II. rode at his coronation, and which had been bred and presented to the king by his lordship; a strange tribute, no doubt, from the veteran hero of republicanism and the covenant. Besides these, several of his manuscripts are preserved in the library at Denton, of which a list has been published in Park's edition of Lord Orford's *Royal and Noble Authors.*

FAIRFORD, a market-town of Gloucestershire, in the hundred of Brightwalls Barrow, 80 miles from London. It is situated on the small river Coln, at its junction with the Thames, over which are two bridges. The church is a remarkably fine Gothic structure, erected about the year 1470 by an individual; and the painted window, said to have been captured by a ship belonging to the founder, a merchant of London, is highly beautiful. It is about three miles from the Thames and Severn Canal, by which some trade is carried on in coals, salt, and other heavy goods. The market is held on Thursday. The population amounted in 1801 to 1326, in 1811 to 1444, in 1821 to 1547, and in 1831 to 1574.

FAIRY, in ancient traditions and romances, signifies a sort of sprite, or imaginary genius, of this lower sphere, and distinguished by a variety of fantastical actions either good or bad.

Fairies were commonly imagined to be women of an order superior to human nature, yet subject to wants, passions, accidents, and even death; sprightly and benevolent whilst young and handsome; morose, peevish, and malignant, if ugly, or in the decline of their beauty; and fond of appearing in white, from which circumstance they were often called the White Ladies.

Concerning these imaginary beings, Jervaise of Tilleberry, marshal of the kingdom of Arles, who lived in the beginning of the thirteenth century, writes thus in a work inscribed to the Emperor Otho IV.:—"It has been asserted by persons of unexceptionable credit, that fairies used to choose themselves gallants from among men, and rewarded their attachment with an affluence of worldly goods; but if they married, or boasted of a fairy's favours, they as severely smarted for such indiscretion." Similar tales still were current in Languedoc; and throughout the whole province there was not a village without some ancient seat or cavern which had the honour of being a fairy's residence, or at least some spring in which a fairy used to lave its tiny form. This idea of fairies has a near affinity with that of the Greeks and Romans concerning the nymphs of the woods, mountains, and springs; and an ancient scholiast on Theocritus says, that "the nymphs are demons which appear on the mountains in the figure of women." The Arabs and other orientals have also their *Peris*, of whom they entertain notions somewhat similar to those held in the west respecting fairies.

But fairies have likewise been described as of either sex, and generally as of small stature, though capable of assuming various forms and dimensions. The most charming representation of these children of romantic fancy is to be found in the *Midsummer Night's Dream*, in referring to which we no doubt have been already anticipated by the recollection of the reader.

Fairy of the Mine, an imaginary being, an inhabitant of mines. The Germans believed in two species: one fierce and malevolent; the other a gentle race, appearing as little old men dressed like the miners, and not much above two feet in height. These sprites wander about the drifts and chambers of the works; seem perpetually employed, yet do nothing; and appear to cut the ore, or fling what is cut into vessels, or turn the windlass; but never do any harm to the miners, unless provoked. Such is the relation of Agricola, in his book *De Animantibus Subterraneis.*

Fairy Circle, or *Ring*, a phenomenon pretty frequent in the fields, and supposed by the vulgar to have been traced by the fairies in their dances. There are two kinds of fairy ring: one of about seven yards in diameter, containing a round bare path, about a foot broad, with green grass in the middle of it; and another of different dimensions, encompassed with a circumference of grass. Jessop and Walker, in the *Philosophical Transactions*, ascribe these rings to lightning; and this is thought to be confirmed by their being most frequently produced after thunder storms, as well as by the colour and brittleness of the grass-roots when first observed. Lightning, like all other fires, moves round, and burns more in the extremity than in the middle; and the second circle arises from the first, as the grass burnt up grows very plentifully afterwards. But others maintain that these circles are formed by ants, which are frequently found in great numbers therein. Mr Cavallo, in his *Treatise on Electricity*, does not think that lightning is at all concerned in the formation of them. "They are not," says he, "always of a circular figure; and, as I am informed, they seem to be rather beds of mushrooms than the effects of lightning."

FAITH, in *Theology*, that assent which we give to a proposition advanced by another, the truth of which we do not immediately perceive from our own reason or experience; or it is a judgment or assent of the mind, the motive of which is not so much any intrinsic evidence, as the authority or testimony of some other who reveals or relates it. Hence, as there are two kinds of authorities and testimonies, the one of God and the other of man, faith becomes distinguished into divine and human. *Divine faith* is that founded on the authority of God; or it is that assent which we give to what is revealed by God. The objects of this faith, therefore, are matters of revelation. *Human faith* is that by which we believe what is told us by men; and its object is matter of human testimony and evidence.

FAITH, in practical theology, constitutes the first of the theological virtues or graces.

Faith in God, in this sense, denotes such a conviction of his being, perfections, character, and government, as produces love, trust, worship, obedience, and resignation. Faith in Christ, as it has been defined by some theologians, is a mere assent to the gospel as true; but according to others, it signifies such a persuasion that he is the Messiah, and such a desire and expectation of the blessings which he has promised in his gospel to his sincere disciples, as engage the mind to fix its dependence upon him, and to subject itself to him in holy obedience. Faith likewise, in respect of futurity, is a moral principle, implying such a conviction of the reality and importance of a future state, as is sufficient to regulate the etmper and conduct in the affairs of this life.

FAITHORN, WILLIAM, an ingenious English artist, a native of London, was the disciple of Peak the painter, with whom he worked three or four years. At the breaking out of the civil war, Peak espoused the cause of his sovereign; and Faithorn, who accompanied his master, was taken prisoner by the rebels at Baringhouse, whence he was sent to London, and confined in Aldersgate. In this uncomfortable situation he exercised his graver; and a small head of the first Villiers, Duke of Buckingham, in the style of Melan, is reckoned as one of his performances at this period. The solicitations of his friends in his favour at last prevailed; and he was released from prison, with permission to retire to the Continent. In France he found encouragement and protection from the Abbé de Marolles; and it was at this time that he formed an acquaintance with Nanteuil, from whose instructions he derived very considerable advantage. About the year 1650 he returned to England, and soon afterwards married the sister of a Captain Cround, by whom he had two sons, Henry, who became a bookseller, and William, an engraver in mezzotinto. Faithorn opened a shop near Temple-Bar, where he sold not only his own engravings, but those of other English artists, and imported a considerable number of prints from Holland, France, and Italy. About the year 1680 he retired from his shop, and resided in Printing-House Yard; but he still continued to work for the booksellers, especially Royston, Martin, and Peak the younger, his former master's brother. He painted portraits from the life in crayons, an art which he had learned of Nanteuil during his abode in France; he also painted in miniature; and his performances in both these styles were much esteemed. But his spirits were broken by the indiscretion and dissipation of his son William; and a lingering consumption put an end to his life in 1691. He wrote a book *Upon Drawing, Graving, and Etching,* for which he was highly commended by his friend Thomas Flatman the poet.

FAKENHAM, a market-town of Norfolk, in the hundred of Gallon, 109 miles from London. It is situated in an open district, but fertile, especially in wheat and barley, with a large corn market on Thursday, but little other trade, since the spinning of worsted has been performed by machinery. The river Var runs near it towards Lynn. The church is a very handsome building. The population amounted in 1801 to 1236, in 1811 to 1382, in 1821 to 1626, and in 1831 to 2077.

FAKIRS, or FAKEERS, Indian monks or friars, some of whom exceed in severities and mortifications the ancient anchorites or solitaries, though the greater part are rogues, who assume this character in order to pass an idle and vagabond life.

FALAISE, an arrondissement of the department of Calvados, in France, extending over 336 square miles. It is divided into five cantons, and these again into 142 communes, containing 71,500 inhabitants. The capital is the city of the same name, situated on the river Ante. It is well built, and contains 13,960 inhabitants, who are occupied in making serges, linen, thread-lace, cotton goods, leather, and cutlery, and in distilling brandy. This place gave birth, in the year 1027, to William the Conqueror, in the castle, the ruins of which are among the finest remains of antiquity in France. Long. 0. 10. W. Lat. 48. 45. N.

FALASHA, a people of Abyssinia, described by Bruce, and supposed to be of Hebrew origin. According to the received accounts, the Falasha are the descendants of those Jews who went from Palestine into Ethiopia, as attendants of Menilek, the son of the queen of Sheba or Saba by Solomon. But the language of this people is very different from the Hebrew, Samaritan, or any other which the Jews ever spoke in their own country. On being interrogated concerning it by Bruce, they said that it was probably one of the dialects spoken by the nations on the Red Sea, among whom they had settled at the period of their first emigration.

FALCADE, in the manège, the motion of a horse when he throws himself upon his haunches two or three times, as in very quick curvets, which is done in forming a stop and half stop.

FALCATED, something in the form of a sickle. Thus, the moon is said to be *falcated* when she appears horned.

FALCO, the eagle and hawk. See ORNITHOLOGY.

FALCON, a name bestowed on various birds of prey, but chiefly on such as are serviceable to man for the pursuit of game. See ORNITHOLOGY *Index*.

FALCONER, WILLIAM, a poet of considerable eminence, born at Edinburgh about the year 1730, was the son of a poor but industrious barber, all of whose children, except the subject of the present notice, were either deaf or dumb. William appears to have passed but a short period at school, where he received the scanty education required to qualify him for an inferior employment; yet he is believed to have contracted a taste for reading, and a desire for higher attainments than his circumstances permitted him to aspire to. At an early age he was entered as an apprentice on board a merchant-vessel belonging to Leith; and Dr Currie mentions, on the authority of a naval surgeon, that he afterwards served as a common sailor on board the ship of which Campbell, author of *Lexiphanes,* was purser, and attracted the notice of that individual by indications of talent which were deemed by him worthy of cultivation. How long he continued in this humble capacity is not known; but by some friendly intervention, he was appointed second mate of a vessel called the Britannia, employed in the Levant trade, which, however, was wrecked during her passage from Alexandria to Venice, and only three of the crew, including Falconer, saved. This event, the date of which has not been ascertained, appears to have made a deep impression on his mind, and probably suggested the idea of his poem entitled *The Shipwreck,* on which his reputation chiefly rests. The first essays of his muse attracted little attention, and were probably commonplace enough; though, if Clarke be right in the opinion that he was the author of "Cease, rude Boreas," an exception must, of course, be made in favour of that popular song. Falconer is supposed to have continued in the merchant service until the spring of 1762, when he recommended himself to the notice of Edward Duke of York, by the dedication of *The Shipwreck,* and enlisted his royal highness amongst the number of his admirers and patrons. Desirous to place him in a situation where he could be befriended, the duke advised him to enter the navy; and before the end of summer, he was rated as midshipman on board the Royal George. But as this ship was paid off at the peace of 1763, and as Falconer's period of service had been far too short to enable him to obtain the commission of lieutenant, he was advised to exchange the military for the civil department of the navy; and, in the course of the same year, he received an appointment as purser of the Glory frigate, a situation which he held until that vessel was laid up in ordinary at Chatham. Being thus once more left without professional employment, he devoted his leisure to literary pursuits. In 1764, he published a new edition of *The Shipwreck*, in 8vo, corrected and enlarged; and the following year appeared *The Demagogue*, a political satire, intended as a sort of antidote to the writings of Wilkes and Churchill, but much more remarkable for virulence than wit. His time, however, was chiefly occupied with the compilation of an *Universal Marine Dictionary*, a work much wanted, and which, when brought out in 1769, was received with general approbation. Before this period he appears to have left his retreat at Chatham for an abode of a less comfortable kind in the metropolis, where, depressed by poverty, that evil-spirit which tracks the footsteps of genius, he subsisted for a time on various resources. But, in the midst of his difficulties, when his situation had become truly distressing, he received an appointment to the pursership of the Aurora frigate, which had been commissioned to carry out to India Messieurs Vansittart, Scrofton, and Forde, as supervisors of the Company's affairs; and he was also promised the office of private secretary to these functionaries. From this favourable turn of fortune the friends of the poet, whilst they rejoiced in the present relief which it afforded, conceived him in a fair way eventually to realize a competent independence; but *dis aliter visum*, Providence had decreed it otherwise. The Aurora sailed from England on the 30th September 1769, and after touching at the Cape of Good Hope, was never more heard of; she was supposed to have foundered in the Mozambique Channel, but not a trace remained by which the cause of the calamity could be discovered, or even conjectured.

Besides the productions already mentioned, Falconer was the author of several pieces, the most considerable of which are an Ode on the Duke of York's second departure from England as rear-admiral, and a Poem on the death of Frederick, Prince of Wales. But as these and similar effusions could never have survived the occasion which produced them, his fame as a poet must entirely rest on *The Shipwreck*, which, with all its faults, has a fair chance of immortality, appealing, as it does, directly to the feelings of one class of men, and indirectly to the natural sympathies of all. There is a warmth in its colouring, and a reality in its descriptions, which strongly impress the minds particularly of youth, and, notwithstanding the didactic character of the poem, sustain its interest, and enliven even the duller parts by a sort of reflected radiance. Natural feeling, natural imagery, and natural truth, are expressed in natural language, which, if it never rises to a great elevation, seldom sinks below the dignity of the subject, and is throughout animated by a glow of feeling which awakens a kindred emotion in the breast of the reader. Falconer has no striking outbursts of genius; he does not aspire to produce a great effect by a few bold touches, or the rapid and masterly grouping of appalling or horrible circumstances. He labours in detail, bringing before us, without apparent effort, the events as they arise, and conducting us with an interest constantly increasing towards the catastrophe. He paints with minute fidelity as well as picturesque effect; but it is from the general result, rather than from any portion or portions of the work considered separately, that the talents of the artist should be judged. Such a tremendous picture of shipwreck as that which Byron has, in wild sportiveness, thrown out in Don Juan, immeasurably transcends the powers of Falconer, and indeed stands alone in its terrible sublimity; but, on the other hand, the latter, by the careful elaboration of natural circumstances, and the general truth of his delineation, ultimately impresses the mind of the reader, if not with such vivid force, perhaps with even more enduring effect. Of the didactic merits of the poem, nautical men, who are necessarily the most competent judges in this particular, have spoken in terms of high commendation; and it has even been said that the rules and maxims therein delivered for the management of a ship in a perilous emergency are the very best which a practical mariner could adopt. But in our estimation this forms one of the principal defects of the poem considered as such, though it fell in with the spirit of the time when *The Shipwreck* was produced, and may still recommend it to sailors; nor by ordinary readers, who cannot understand or appreciate this sort of instruction, is it likely to be viewed in any other light than as an incumbrance to the march of the narrative and the progression of events.

FALCONRY, a field sport considered as of high importance in former ages, though greatly fallen into disuse in recent times. See FALCON in ORNITHOLOGY *Index*.

FALKIRK, a town of Scotland, in the county of Stirling. It is beautifully situated on the face of an eminence which overlooks the wide expanse of country called the Carse of Falkirk, and consists of one broad street, with a number of narrow streets and lanes branching off from it, or running parallel to it. The houses are in general lofty and well built; and the High Street is ornamented by a spire and clock of modern erection. Besides the parish church, there are a number of meeting-houses for dissenters. Several fine villas have recently been built towards the north of the town, and form a handsome continuation of it, uniting it with the villages of Grahamstone and Bainsford. Falkirk enjoys considerable trade; but the only manufacture carried on is one of leather. The inland trade constitutes the support of the town, the populous neighbourhood being supplied by it with most of the necessaries of life. The Carron iron-works, which are very extensive, are situated about two miles north of the town, and the numerous individuals there employed make Falkirk their general market. There are also some extensive coal-works, distilleries, malt-works, and flour-mills, in the immediate neighbourhood; and brewing is carried on to some extent. Falkirk is thus calculated to be a commercial depôt for a population amounting to nearly thirty thousand individuals. The town is chiefly noted for its three great cattle markets or *trysts*, held annually in August and the two following months. These markets are considered as amongst the largest in Great Britain, and to them a vast quantity of live stock of every description is brought. The traffic carried on in Falkirk is assisted by branches of the Bank of Scotland and Commercial Banking Company. It was at one time a burgh of barony under the earls of Linlithgow; but since the fall of that family, and the abolition of the heritable jurisdictions, it has possessed no form of municipal government. The affairs of the town are administered by a body of stent-masters, chosen by the different trades. A justice-of-peace court is held on the first Monday of every month. Falkirk is a town of considerable antiquity, and appears to have been a place of some note in the early part of the eleventh century. Its original name was Eglisbreck, which signifies the "speckled church," in allusion, it is supposed, to the colour of the stones, and translated by Buchanan *varium sacellum*. The old church, which was demolished in 1810, was erected in 1057, the year in which Malcolm Ceanmore assumed the sovereignty. The new church, which was built upon the site of the old one, in front of the town, is a very plain edifice, with an ancient spire attached to it. In the neighbourhood of this town was fought a celebrated battle between the Scotch and English, during the period when Edward I. of England attempted to usurp the sovereignty of Scotland. The Scotch, under Cuming of Badenoch and the renowned Sir William Wallace, were worsted, and two Scottish chiefs, Sir John Graham and Sir John Stewart, fell in the conflict. Their graves are still pointed out in the churchyard; and over the former a monument was erected with an inscription, which has been from time to time renewed. A second battle was fought here on the 17th of January 1746, between the royalists and the insurgents under Prince Charles Edward Stuart. The population of Falkirk, in 1821, amounted to 4000, and in 1831, including the parish, to 12,743. It is at the distance of twenty-four miles from Edinburgh, and twenty-two from Glasgow.

FALKLAND, a small town of Scotland, in the county of Fife, and the chief place of a parish of the same name. It is situated in rather a secluded part of the district, some miles west from the great thoroughfare through the county. It consists of a single street, broad and spacious at the east end, but insignificant at the opposite extremity, with several cross lanes. The houses are in many cases covered with thatch, and of an antique and primitive appearance. The chief occupation here is weaving; but there is little or no traffic of any kind. The principal attraction in Falkland is the royal palace, originally a stronghold belonging to the Macduffs, earls of Fife. On the attainder of Munro Stewart, the seventeenth earl, it became forfeited to the crown in 1424. James V. who was very fond of the place, enlarged and improved it. The remains evince its former magnificence and elegance, and the fine taste of the princely architect. The gateway is placed between two fine round towers, and on the right hand adjoins the chapel, whose roof is of wood, handsomely gilt and painted, but in a most ruinous condition. Beneath are several apartments. The front next to the court was beautifully adorned with statues, heads in bas-relief, and elegant columns not reducible to any order, but of fine proportion, with capitals approaching the Ionic scroll. Beneath some of these pillars was inscribed I. R. M. G. 1537, or *Jacobus Rex, Maria de Guise.* This place was also a favourite residence of James VI. on account of the fine park and abundance of deer. The east side was accidentally burnt in the time of Charles II. and the park ruined during Cromwell's usurpation, when the fine oaks were cut down in order to build a fort at Perth. There are various historical associations connected with Falkland. In a dungeon of the original castle, which is supposed to have constituted the north side of the court-yard of the palace, Robert, Duke of Rothesay, brother of James I. was ~~starved~~ to death by his uncle Albany. Falkland was erected into a burgh by James II. in 1458; and in 1595 James VI. renewed and confirmed its charter. The population of the place amounted in 1821 to 1050, and in 1831 to 2658.

Falkland, *Lord.* See Carey.

FALL, the descent of a heavy body towards the centre of the earth. It is also the name of a measure of length used in Scotland, containing six ells.

Fall of Man, in sacred history, that memorable event by which sin and death were introduced into the world. The account which Moses has given of this transaction is extremely concise; and hence several learned men, finding a difficulty in interpreting his statement, have been inclined to believe that all which is contained in Scripture on the subject ought to be taken in an allegorical sense, and not according to the strictness of the letter. They allege that the ancients, particularly the eastern nations, had two different ways of delivering their divinity and philosophy, one popular, and the other mysterious; that the Scripture uses both occasionally, sometimes accommodating itself to the capacities of the people, and at other times to the real but more veiled truth; and that, to obviate the many difficulties which occur in the literal history of this sad catastrophe, the safest way is to understand it as a parabolical story, under which the real circumstances are disguised and concealed, as a mystery not fit to be more explicitly declared.

FALLING Sickness, or Epilepsy. See Medicine.

Falling-Stars. See Star.

FALLOPIAN Tubes, in *Anatomy*, two ducts arising from the womb, one on each side of the fundus, and thence extending to the ovaria, and which have a considerable share in conception. They are called *tubæ*, from their form, which bears some resemblance to a trumpet; and their denomination of Fallopian they derive from Gabriel Fallopius, by whom they were first discovered.

FALLOPIUS, or Falloppio, Gabriel, a celebrated anatomist and surgeon of the sixteenth century, was born at Modena in 1523. Although he taught anatomy with great distinction, and enjoyed an immense reputation, the details of his life are not exactly known, and have been variously related by different biographers; some, as Tommasini and Ghilini, fixing his birth in 1490, which is a manifest error, refuted by Fallopius himself; and others, again, contending that he was the disciple of Vesale, although Martine and Haller attest the contrary. But be this as it may, Fallopius made great progress in medical study, first at Ferrara under Antonio Musa Brassavola, and afterwards at Padua. For a time, indeed, he possessed a canonry in the cathedral of Modena; but he soon renounced this function, which prevented him from indulging his taste for dissection. After having taught anatomy for some months in the university of Ferrara, and during three years in that of Pisa, he was chosen by the senate of Venice, in 1551, to fill the chair of anatomy and surgery at Padua. He was, besides, entrusted with the demonstration of medicinal plants, and the inspection of the botanic garden, which he enriched with several vegetables collected during his travels in Italy, France, and Greece. But whilst discharging with equal zeal and distinction the various duties which these functions imposed upon him, his career was suddenly arrested by death, on the 9th of October 1562, before he had attained the fortieth year of his age. Fallopius only published a single work, which is not voluminous, but full of curious facts and useful discoveries; it is entitled *Observationes Anatomicæ*, Venice, 1561, in 8vo, also, Padua, 1562, Paris, 1562, Cologne, 1562, Helmstadt, 1588; and certainly forms an epoch in the annals of anatomical science. It is the first work, indeed, in which we find the exact osteology and augiology of the fœtus; notions perfectly sound in regard to the epiphyses; and a luminous description of the delicate and complicated organ of hearing. The illustrious author clearly makes known the cochlea, the demi-circular canals, and the tortuous canal, which still bears the name of Fallopius. He describes, with a care formerly unknown, the ethmoid and sphenoid bones, the alveolar processes in which the teeth are encased, and the arteries, with the veins and nerves connected with them. He has likewise bequeathed his name to the ligament which runs from the anterior point of the ileon to the symphysis pubis. He points out, sometimes individually, at other times with more of method and detail, the occipital, palatine, laryngian, pharyngian, and pyramidal muscles of the abdomen; also the auricular, ocular, and facial muscles; together with the elevator of the eyebrow, and the sphincter of the bladder. Less profound in the knowledge of the vessels, he nevertheless enriched that portion of anthropotomy. Before his time anatomists had the most confused and inaccurate ideas respecting the sinus of the spinal marrow, the carotid, meningean, and ethmoidal arteries, the jugular and vertebral veins, and the origin of the artery of the penis. Nor was neurology less indebted to the researches of Fallopius, who discovered the fourth pair of nerves, enumerated the three branches of the fifth, and completed the description of the eighth. Lastly, he carried the same critical spirit into splanchnology in general, over which he diffused much light, particularly in regard to the different sets of apparatus for secreting the bile, the urine, and the semen ; and he also traced an excellent description of the clitoris, of the round ligaments, and of the extremities of the womb. To this enumeration of the anatomical labours of Fallopius it may be added, that he was powerfully seconded in his efforts by the principal men of the state. The protection afforded him by the grand duke of Tuscany was carried a length which may probably strike our readers with horror : *Princeps jubet ut nobis dent hominem, quem nostro modo interficimus, et illum anatomisamus.* The unfortunate men here alluded to were no doubt criminals ; yet it is impossible to avoid being shocked beyond expression by the perusal of these words. The lectures of Fallopius were published, after his death, by several of his disciples ; but none of the latter seems to have performed this task in a manner either creditable to himself or worthy of the great teacher of anatomy by whom they were delivered.

FALMOUTH, a sea-port of the county of Cornwall, in the hundred of Kerriar, 273 miles from London, at the spot where the river Fale falls into the sea. It has risen to importance from the excellence of its harbour, which is capable of containing large fleets of heavy ships in perfect security ; though difficult to get out of when the wind is easterly, and consequently fair for the passage across the Atlantic. The Lisbon packets sail regularly from this port, and at one period a beneficial trade was extensively carried on by them. Falmouth has now a considerable trade in the pilchard fishery. Near to it is Pendennis Castle, one of the defences of the harbour, built in the reign of Henry VIII., improved by Elizabeth, and greatly strengthened by Cromwell. It was occupied as a prison for Americans captured at the early stages of the war with the colonies in 1776. There are markets on Tuesday, Thursday, and Saturday. The population amounted in 1801 to 4849, in 1811 to 5307, in 1821 to 6374, and in 1831 to 7284.

FALSE, in general, something contrary to truth, right, or justice. Thus, we say a false action, false weights, false claim, and the like.

FALSI CRIMEN, in the civil law, is fraudulent subornation or concealment, with design to darken or hide the truth, and make things appear otherwise than they are. The *crimen falsi* is committed, first, by words, as when a witness swears falsely ; secondly, by writing, as when a man antedates a contract, or the like ; and thirdly, by deed, as when he sells by false weights and measures.

FALSIFY, in *Law*, is used for proving any thing to be false. Hence we find falsifying a record for showing it to be erroneous.

FALSTER, an island in the Baltic, forming a part of the kingdom of Denmark. It is separated from Zealand by the Gaade Sound, from Langeland by Guldborg Sound, and from Moen by Green Sound. In extent it is 184 square miles, and contains 16,500 inhabitants, in two cities and thirty parishes. Its produce of corn exceeds its consumption ; and it assists other parts of the kingdom with some supplies of butter, meal, live cattle, and fruit. The chief town is Mykopping, on Guldborg Sound.

FALU, one of the provinces of northern Sweden. It is bounded on the north by Hernosand, on the east by Gefleborg, on the south-east by Wastera, on the south by Orebro, on the south-west by Carlstadt, and on the west by Norway. It extends over 12,980 square miles, comprehends three cities, one market-town, and 1747 insulated establishments, and contains 124,816 inhabitants. The province is generally mountainous, the highest points rising to about 4000 feet above the level of the sea. Some agriculture is practised in the southern part, and rye, barley, and oats are grown ; but in the north nothing is to be seen except barren wastes. There are annually upwards of 2000 head of cattle brought from other parts to supply the few inhabitants who can afford to indulge in their flesh. The chief products are wood, potash, pitch, and tar from the soil, and iron, copper, and porphyry from the mines.

FALU, a town of Sweden, the capital of the province of that name. It is situated between the lakes Warpen and Runn, on a river which flows from one to the other. It is an ancient town, containing chiefly wooden houses to the number of 1135, and 4709 inhabitants, who chiefly find employment in the mines around them, but in some degree from various manufactures. Long. 15. 29. 34. E. Lat. 60. 35. 49. N.

FAMA CLAMOSA, in the judicial procedure of the church of Scotland, a ground of action before a presbytery against one of its members, independently of any regular complaint by a particular accuser.

Any person who is of good character may prefer to the presbytery a complaint against one of their members ; but the presbytery is bound not to proceed to the citation of the person accused, until the accuser under his hand shall give in the complaint, with some account of its probability, and undertake to make out the libel, under the pain of being considered as a slanderer. But when such an accusation is brought before them, they are obliged to examine or try the case. Besides this, however, the presbytery considers itself obliged to proceed against any of its members, if a *fama clamosa* of the scandal is such that the person implicated cannot be vindicated unless they begin the process. This they can do without any particular accuser, after they have inquired respecting the origin, occasion, and authors of this report. It is a maxim in the kirk of Scotland, that religion must suffer if the scandalous or immoral actions of a minister are not corrected ; and wherever a minister is reputed guilty of any immorality, although previously the most popular preacher in the kingdom, none almost will attend upon his ministry. Therefore the presbytery, for the sake of religion, is obliged to proceed against a minister in case of a *fama clamosa*. This, however, is generally done with great tenderness. After they have considered the report raised against him, they then order him to be cited, and draw out a full copy of what is reported, with a list of the names of the witnesses to be produced for proving the allegation. He is then formally summoned to appear before them ; and he has notice served upon him, at least ten days before the time of his appearance, to give in his answers to what is termed the *libel*. If at the time appointed the minister appear, the libel is read to him, and his answers are also read. If the libel be found relevant, then the presbytery endeavours to bring him to a confession. If a minister absent himself by leaving the place, and prove contumacious, without making any relevant excuse, a new citation is given him, and intimation is made at his own church when the congregation is met, that he is to be holden as confessed, since he refused to appear before them ; and accordingly he is deposed from his office.

FAME, a heathen goddess, celebrated chiefly by the poets. She is feigned to have been the last of the race of Titians produced by the earth, to have had her palace in the air, and to have possessed a vast number of eyes, ears, and tongues. She is mentioned by Hesiod, and particularly described by both Virgil and Ovid.

FAMIA, or Famieh, a town of Syria, the ancient Apamea. Here, under the rule of the Seleucidæ, was a school and nursery for cavalry, where 30,000 horses and 500 elephants were fed. There are now only a few buffaloes and sheep. It is thirty miles north of Damascus. Long. 36. 43. E. Lat. 35. N.

FAMILIARS of the Inquisition, persons who assist in apprehending such as are accused, and carrying them to prison. They are assistants to the inquisitor, and called *familiars*, because they belong to his family. In some provinces of Italy they were called *cross-bearers*, in others the *scholars of St Peter the Martyr*; and they wore a cross in front on the outside of the garment. They are properly bailiffs of the inquisition; and the office is esteemed so honourable, that in Portugal noblemen have been ambitious of belonging to it.

FAMILY denotes the persons who live together in one house, under the direction of one head or chief manager. It also signifies the kindred or lineage of a person; and is used by old writers to indicate a hide or portion of land sufficient to maintain one family.

Family, in *Natural History*, a term used to express any order of animals, or other natural productions, which exhibit certain affinities, or the same characters.

Family Islands, a cluster of small islands near the north-east coast of New Holland, and twelve miles northwest of Cape Sandwich.

FAN, a machine employed to produce coolness by agitating the air. That the use of the fan was known to the ancients is very evident from what Terence says:

> Cape hoc *flabellum*, et ventulum huic sic facito;

and also from the words of Ovid,

> Profuit et tenues ventos movisse *flabello*.

The fans of the ancients were made of various materials; but the most elegant were composed of peacocks' feathers, or perhaps painted so as to represent these.

In the Greek church, a fan is put into the hands of the deacons in the ceremony of their ordination, in allusion to a part of the deacon's office in that church, which is to keep the flies off the priests during the celebration of the sacrament.

What is called a *fan* amongst us is a thin skin, or piece of paper, taffety, or other light stuff, cut semicircularly, and mounted on several little sticks of wood, ivory, tortoise-shell, or the like.

Fan is also an instrument used to winnow corn. The machine employed for this purpose by the ancients seems to have been of a form similar to ours. The fan, which Virgil calls *mystica vannus Inachi*, was used at initiations into the mysteries of the ancients. For as the persons who were initiated into any of the mysteries required to be particularly good, the instrument which separates the wheat from the chaff was a fit emblem of setting apart the good and virtuous from the vicious and useless part of mankind.

FANATICS, enthusiastic, visionary persons, who pretend to revelation and inspiration. The ancients called those *fanatici* who passed their time in the *fana* or temples, and being often seized with a kind of enthusiasm, as if inspired by the divinity, showed wild and antic gestures. Prudentius represents them as cutting and slashing their arms with knives.

FANCY. See Imagination.

FANIONS, in the military art, small flags carried along with the baggage.

FANNERS, a machine for winnowing corn, or for separating the chaff from the grain. See Agriculture.

FANO, a city of the delegation Urbino, in the papal dominions, in Italy. It is situated on an arm of the river Metauro, on the sea shore, is surrounded with walls, and contains a cathedral, sixteen parish churches, nine monasteries, and five nunneries, a large opera house, and many handsome private houses, with a population of 14,670 persons, who depend for subsistence on the various branches of the silk trade, and on the fishery from its port. Long. 12. 54. 33. E. Lat. 43. 51. N.

FANSHAWE, Sir Richard, a distinguished cavalier in the heroic age of the civil wars and the protectorate, was the youngest son of Sir Henry Fanshawe, brother of Lord Viscount Fanshawe of Dromore in Ireland, and born at Ware-park, Hertfordshire, in June 1608. He had only attained his seventh year at the time of his father's death, when the care of his education devolved on his mother, who placed him under the celebrated schoolmaster Thomas Farnaby, and, in due time, sent him to Cambridge, where he was admitted as a fellow-commoner of Jesus College in November 1623. Having prosecuted his studies with success, and, in particular, discovered a taste for classical learning, he was, in January 1626, removed to the Inner Temple; but at his mother's death, which happened soon afterwards, he resolved to pursue a line of life more congenial to his inclination, and, with this view, he visited France and Spain, where, in the course of his travels, he acquired the languages and studied the manners and institutions of those countries. On his return to England he was appointed secretary of legation to the embassy at Madrid, whither he immediately repaired, and was left as chargé d'affaires at the Spanish court from the time of Lord Aston's resignation till the appointment of Sir Arthur Hopton as his successor in 1638.

On the breaking out of the civil war, Fanshawe, being then in England, declared at once for the king, and was entrusted with several important employments. In 1644, whilst attending the court at Oxford, he was made secretary to the Prince of Wales, whom he accompanied in his expedition to the western parts of England, and thence to the islands of Scilly and Jersey. In 1648, he was appointed treasurer of the navy under Prince Rupert, an office which he held till 1650, when he was created a baronet, and sent to Madrid to represent the necessitous condition of the king his master, and to implore assistance from Philip IV. Recalled to Scotland, where Charles II. had now made his appearance, he served there in the capacity of secretary of state, but without taking either the covenant or the engagement; and being recommended by the king to the York party, he was received with great kindness by the latter, and entrusted with the broad seal and signet. In 1651, Sir Richard was taken prisoner at the battle of Worcester, conveyed thence to London, and there committed to close custody; but having contracted a dangerous illness, he was liberated on giving bail to the amount of four thousand pounds, chiefly, as would appear, through the intercession and influence of Cromwell. In 1654, we find him at Tankerley-park, which he had hired of his friend Lord Strafford, to whom he dedicated his translation of the *Lusiad* of Camoens, written during his residence there. Early in 1659, he obtained the discharge of his bail, on pretence of going abroad with the eldest son of the Earl of Pembroke, and immediately repaired to Breda, where Charles II. received him with open arms, knighted him, and appointed him master of requests and Latin secretary.

On the restoration, Sir Richard expected, from a promise which had been formerly made to him, to be appointed secretary of state; but, through the paramount influence of Monk, Duke of Albemarle, the office was conferred on a creature of his own, Sir William Morrice. "The king," says Lady Fanshawe, in her *Memoirs*, "promised Sir Richard that he should be one of the secretaries of state, in the event of his restoration, and both the Duke of Ormond and Lord Chancellor Clarendon were witnesses to it; but that false man (Monk) made the king break his word for his own accommodation, and placed Mr Morrice, a poor country gentleman of about L.200 a year, a fierce presbyterian, and one who never saw the king's face; but still promises were made of the reversion to Sir Richard." In the parliament which met on the 8th May 1661, he took his seat as one of the representatives of the university of Cambridge, and was soon afterwards sworn a privy counsellor for Ireland. He was then sent as envoy extraordinary to Portugal; and being shortly afterwards appointed ambassador to the court of that country, he negotiated the treaty of marriage between Charles II. and the Infanta Donna Catharina, daughter of John VI. and returned to England towards the close of the year. In 1662 he was again sent as ambassador to the court of Lisbon, and, on his return to England the following year, was sworn a member of the privy council. Being considered by the king of Portugal as the fittest person to bring about an accommodation between that country and Spain, Sir Richard was, in the beginning of 1664, sent as ambassador to the court of Philip IV. by whom he was received with the most flattering marks of distinction, under the impression, as appears, that he was authorized, on the part of England, to give up Tangier and Jamaica to Spain. The Spaniards, however, finding themselves disappointed in this expectation, altered their tone; and cordiality having given place to coldness and distrust, the ambassador found himself exposed to frequent mortifications, and involved in the greatest perplexities. At the earnest desire of Spain he had made a journey to Lisbon, for the purpose of endeavouring to bring about an accommodation with Portugal, but returned without effecting any thing. At length, however, when the life of Philip IV. appeared to be drawing towards a close, a project of a treaty, containing greater commercial advantages, and insisting on fewer inconvenient conditions, than any that had formerly been proposed, was suddenly submitted to him, accompanied with an urgent demand of immediate acceptance or rejection, on account of the king's illness, which, it was alleged, might be followed by an entire change in the Spanish councils. In this emergency, the ambassador, after comparing the project with his instructions, and suggesting certain additions and modifications, which were agreed to, consented to sign the treaty, to which was annexed a secret article respecting Portugal, and immediately transmitted it to England. But objections having been taken to it in council, chiefly on the ground that the ambassador had exceeded his powers, the king was advised to withhold his ratification, and Sir Richard was in consequence recalled. But whilst he was preparing to return home, he was, on the 4th of June 1666, seized with a violent fever, which put an end to his life, at Madrid, on the 16th of the same month, the very day on which he had intended to take his departure for England.

Sir Richard Fanshawe was married in Wolvercot church, near Oxford, on the 18th May 1644, to a daughter of Sir John Harrison, by whom he had six sons and eight daughters, of whom only one son and four daughters survived him. Lady Fanshawe was related to her husband, inasmuch as her mother was daughter to Robert Fanshawe, Esq. of Fanshawe-gate, grand-uncle to Sir Richard. She is also the author of *Memoirs* which she composed for the use of her only surviving son, and which, besides many traits of natural feeling and noble sentiment, contain a very interesting account of the losses and sufferings of the Fanshawe family in the royal cause, and more particularly of the proceedings of her husband, Sir Richard, to whom she seems to have been most affectionately attached, and of whom, from the time of their marriage, she was the constant companion, amidst all the difficulties and perils of those troubled times. For a very judicious and discriminating notice of these *Memoirs* the reader is referred to the *Edinburgh Review* (vol. l. p. 75.)

Although much of Sir Richard Fanshawe's life was spent in active employment, he found leisure to produce the following works: 1. An English translation, in verse, of Guarini's *Pasto Fido*, 1646, in 4to; 2. A translation from English into Latin verse of Fletcher's *Faithful Shepherdess*, 1658; 3. An Ode on the king's proclamation in 1630, an English translation of the fourth book of the Æneid, Odes of Horace translated into English, and a Discourse of the Civil Wars of Rome, inserted in the octavo edition of the *Faithful Shepherdess;* 4. A translation of the *Lusiad* of Camoens, 1655, in folio; 5. Two pieces, entitled, *Querer per solo querer*, published after his decease, 1671, in 4to, and *Fiestas de Aranjuez*, both written by Antonio de Mendoza in 1623, and translated into English by Sir Richard in 1654; 6. Correspondence, entitled *Original Letters of his Excellency Sir Richard Fanshawe, during his Embassy in Spain and Portugal.*

FANTASIA, in the Italian music, signifies *fancy*, and is used for a composition, in which the composer ties himself to no particular time, but ranges according as his fancy, amidst various movements and different airs, dictates. This is also called the capricious style. Before sonatas were used, many compositions of this kind appeared, some of which even now remain.

FANUM, among the Romans, a temple or place consecrated to some deity. The deified men and women among the heathens had likewise their *fana;* and Cicero even erected one to his daughter Tullia.

FARAHA, a town of Arabia, on the south coast of the Persian Gulf, 200 miles east-south-east of El Catif. Long. 51. 30. E. Lat. 25. 7. N.

FARANDMAN, a traveller, or merchant stranger, to whom, by the laws of Scotland, justice ought to be done with all expedition, that his business or journey be not hindered.

FARCE was originally a droll petty show or entertainment, exhibited by charlatans, and their buffoons, in the open street, in order to gather the crowd together. The word is French, and signifies, literally, forced meat or stuffing. It was applied on this occasion on account of the variety of jests, gibes, and tricks, with which the entertainment was interlarded. Some authors derive the word farce from the Latin *facetia;* others from the Celtic *farce*, mockery; and others from the Latin *farcire*, to stuff.

Modern dramatists have reformed the wildness of the primitive farces, and brought them to the taste and manner of comedy. The difference between the two on our stage is, that comedy keeps to nature and probability; whereas farce disallows all laws, or rather upon occasion sets them aside. Its end is purely to excite mirth; and it sticks at nothing which may contribute thereto, however wild and extravagant. Hence the dialogue is usually low, the persons of inferior rank, the fable or action trivial or ridiculous, and nature and truth everywhere heightened and exaggerated, to afford the more palpable ridicule. See DRAMA.

FARDAPOOR, a town of Hindustan, in the province of Berar. The fort is of no strength. It is forty-three miles north-west of Jalnapoor. Long. 76. 12. E. Lat. 20. 29. N.

FAREHAM, a market-town of the county of Southampton, in the hundred of its own name, seventy-two miles from London. It stands nearly at the head of Portsmouth harbour, and vessels of considerable burden can discharge their cargoes there. It is resorted to in the summer for the purpose of sea-bathing. There is a corporation who regulate the local business of the town. The market is held on Wednesday. The inhabitants amounted in 1801 to 3030, in 1811 to 3225, in 1821 to 3677, and in 1831 to 4402.

FAREWELL Cape, on the north-west coast of Tavai Poenammoo, the southern island of New Zealand. Long. 186. W. Lat. 40. 33. S.

FARLEU, money paid by the tenants in the west of England, in lieu of a heriot. But in some manors of Devonshire, farleu is often distinguished as the best goods, whilst heriot is the best beast, payable at the death of a tenant.

FARM, Farin, or *Ferm* (*Firma*), in *Law*, signifies a little country messuage or district, containing house or land, with other conveniences, and which is hired or taken by lease, at a certain yearly rent. See Agriculture.

In the corrupted Latin, *firma* signified a place inclosed or shut in; and hence, in some provinces, as Ménage observes, they call *closerie*, or *closure*, what in others they call a *farm*. We also find *locare ad firmam*, signifying to let to *farm*; probably on account of the sure hold the tenant here has in comparison of tenants at will.

Spelman and Skinner, however, chuse to derive the word *farm* from the Saxon *fearme*, or *feorme*, that is, *victus*, provision; by reason of the country people and tenants having anciently paid their rents in victuals and other necessaries, which were afterwards converted into the payment of a sum of money. Hence a *farm* was originally a place which furnished its landlord with provisions. Amongst the Normans, farms which pay in kind, that is, in provisions, and those which pay in money, are still distinguished; the former being simply called *fermes*, and the latter *blanche ferme*, or white farm.

Spelman shows, that the word *firma* anciently signified not only what we now call a *farm*, but also a feast or entertainment, which the farmer gave the proprietor or landlord, during a certain number of days, and at a certain rate, for the lands held of him. Thus *fearme* in the laws of King Canute has been rendered *victus*; and thus also we read of *reddere firmam unius noctis*, and *reddebat unum diem de firma*, denoting provision for a night and day. About the time of the conquest rents were all paid in provisions; a custom which is said to have been first altered under King Henry I. We also speak of *farming* duties, imposts, and the like.

FARMER, he who tenants a farm, or is lessee thereof; and generally every lessee for life, years, or at will, is called *farmer*. As this word implies no mystery, except it be that of husbandry, husbandman is the proper addition for a farmer.

Farmer, *Hugh*, an English clergyman and a man of letters, belonging to the protestant nonconformists, was descended from people of respectability in North Wales, and first drew breath at Shrewsbury, in the year 1714. Dr Charles Owen was for some time his tutor; but previously to the period when he was under that master, he had been at a school in Llanegrin. His parents from the first having designed him for the ministry, he was in 1730 sent to prosecute his studies under Dr Doddridge at Northampton. Here, by the rectitude of his conduct and wonderful proficiency, he gained the esteem of that excellent person, who always spoke of him in the most respectful terms. Having completed his academical studies, Mr Farmer became the chaplain of William Coward, Esq. of Walthamstow, in the county of Essex, and was at the same time chosen minister of a dissenting congregation in that village. But notwithstanding the gratitude with which Mr Coward deserves to be remembered by many for his charitable institutions, he had certain peculiarities of temper which rendered him a very disagreeable companion. His doors were shut at an uncommonly early hour of the night, and neither visitor nor resident could afterwards obtain admission. Mr Farmer having one evening been detained a little beyond that hour, found the doors shut against him, and was under the necessity of applying to a Mr William Snell, solicitor, a man of eminence, and possessed of many excellent qualifications. In the family of this gentleman he remained for about thirty years, living in the greatest friendship and intimacy. Here also he gradually prepared those valuable treatises and dissertations which were afterwards given to the public, and which acquired him so much celebrity as a man of letters. He likewise continued to discharge the duties of his ministerial function to the people of Walthamstow.

When a day of thanksgiving was appointed for the suppression of the rebellion in 1745, Mr Farmer preached a sermon on that occasion, which was published the following year. His next work was of much greater importance, being entitled, An Inquiry into the Nature and Design of our Lord's Temptation in the Wilderness. In this production it was the design of Mr Farmer to prove that the whole was transacted in vision, the different stages of which were intended to point out to him the difficulties and duties of his subsequent ministry. The originality of thought and profound erudition which this work displayed, soon obtained for it a very extensive circulation, and called forth the exertions of those who were of an opposite opinion. It received one reply under the title of Christ's Temptations real Facts, which possessed considerable merit, but was much inferior to Mr Farmer's in energy of expression, depth of thinking, and force of argument. But the most masterly, perhaps, of all Mr Farmer's literary productions was his Dissertation on Miracles, designed to show that they are arguments of a divine interposition, and absolute proofs of the mission and doctrine of a prophet; a work which was first published in the year 1771. But as great talents are frequently envied, so this work of Mr Farmer was declared by some to have been chiefly borrowed from Lemoine's treatise on the same subject; slander which he refuted in a very able and satisfactory manner. In the year 1775 he published his celebrated Essay on the Demoniacs of the New Testament, which may be considered as the completion of the design he had in view by his dissertation on miracles. The hypothesis which he adopted had formerly been defended with great ability by Mede, Sykes, Lardner, and others; but it was reserved for the critical acuteness of Mr Farmer to free it from those difficulties with which it was surrounded, and to place the subject in a much clearer light. His essay on demoniacs was successively attacked by Dr Worthington and Mr Fell, both of them men of considerable erudition, but much inferior in ability to their antagonist.

Mr Farmer having continued for several years the sole pastor of the congregation at Walthamstow, an able colleague was appointed him in 1761, in consequence of which he became the afternoon preacher to the congregation of Salter's Hall, in the city of London, and soon afterwards the Tuesday lecturer at the same place. But he resigned his ministerial employments as he advanced in years, a circumstance which the people committed to his charge very much regretted. In the year 1785 an affection in his eyes nearly deprived him of sight, but by means of a surgical operation he was for some time enabled to resume his studies. Mortality is, however, the inevitable lot of all men, and in 1787 the growing infirmities of Mr Farmer brought him to the grave, in the seventy-third year of his age.

Farmer, *Richard*, D. D. a scholar and critic of considerable eminence, was the son of a hosier at Leicester, at which place he was born in the year 1735. Here he received the rudiments of his education, and afterwards became a student at Cambridge, and pensioner of Emanuel College. He was considered as a young man well acquainted with books, much esteemed among his friends, and looked upon as possessed of lively parts, even before he had acquired any extraordinary reputation as a scholar. He was made bachelor of arts in 1757, and master of arts in 1760. Several years after this period, having been for some time a curate, he took the degree of bachelor in divinity, and became a preacher at Whitehall. Besides the attention he paid to the Greek and Roman authors, he prosecuted the study of books in his own language, printed in black letter, and thus laid the foundation of a work which added more to his literary reputation than any other performance. This was an Essay on the Learning of Shakspeare, which he published in 1766. Men of letters had long turned their attention to the learning of Shakspeare, in order to ascertain its real extent. It could not be questioned that he was acquainted with the history and mythology of the ancients, but it was still a matter of dispute from what sources that acquaintance had been derived. To obviate this difficulty, Mr Farmer's knowledge of books enabled him to demonstrate, that translations of the far greater part of the classical authors were to be met with in the time of our distinguished dramatist; and as he showed that Shakspeare had even copied the blunders and errors of these translations, he made it manifest beyond the possibility of a rational doubt, that he was wholly incapable of consulting the originals. This essay passed through three editions in a very short time, and was much admired for the sprightliness of its composition, whilst the readers of it were in general persuaded that he had fully established his point.

This performance brought him into notice, and became extremely favourable to his professional advancement. By the influence of Bishop Hurd, he procured the chancellorship and a prebend in the cathedral of Lichfield; and in 1775 he was elected master of Emanuel College, and took the degree of doctor in divinity. He was soon afterwards appointed principal librarian to the university, and served in turn the office of vice-chancellor. He was made prebendary of Canterbury by Lord North, at that time prime minister, and Mr Pitt twice offered him a bishopric; but the constraints and solemnity of the episcopal character were not congenial to his natural temper, on which account he declined the offer, and having resigned his office as prebendary, he accepted of a residentiaryship of St Paul's. This obliged him to reside three months annually in London, which he spent with equal pleasure and advantage in the society of literary men. From nature he inherited a fund of good humour, and was of such an obliging turn, that he buried party spirit in the satisfaction which he found in the performance of beneficent actions. Though in general an enemy to reforms of every kind, and anxious to preserve things as they were, both in church and state, he was nevertheless instrumental in amending the police of Cambridge, especially as it related to the paving and lighting of the streets. At his instigation also, monumental sculpture was admitted into the cathedral of St Paul's, and will continue to exhibit a striking proof of national gratitude, as well as serve to cover the nakedness of the walls.

It was at one time the intention of Dr Farmer to publish a history of the town and antiquities of Leicester; but either his independent circumstances, or a degree of native indolence, made him relinquish the design, and the few materials which he had collected were therefore given to Mr John Nichols, at that time engaged in an elaborate work on the same subject. After a painful illness of some length, Dr Farmer died at Emanuel College in the month of September 1797, in the sixty-second year of his age. Dr Parr wrote an epitaph for his tombstone, in which we find the following testimony to his worth: *Vir facetus et dulcis, festique sermonis, Græce et Latine doctus, in explicanda veterum Anglorum poesi subtilis et elegans.*

FARNABIE, Thomas, son of a carpenter in London, and born in 1575, staid a short time at Oxford, where being enticed to abandon his religion, he went to Spain, and was there educated in a college belonging to the Jesuits. Being weary of their severe discipline, he accompanied Sir John Hawkins and Sir Francis Drake in their last voyage in 1595. He was afterwards a soldier in the Low Countries; but being reduced to great want, he returned to England, where, wandering about for some time under the name of Thomas Bainrafe, the anagram of his name, he settled at Mattock in Somersetshire, and there taught a grammar school with good reputation. He afterwards removed to London, and opened a school with large accommodations for young gentlemen. Whilst he taught this school, he was made master of arts at Cambridge, and incorporated into the university of Oxford. In 1636, he removed to Seven Oaks in Kent, and taught the sons of several noblemen and gentlemen, who boarded in his house, with great success, and grew rich. His works gained him reputation. Upon the breaking out of the civil commotions in 1641, he was cast into prison, and it was debated in the House of Commons whether he should be sent to America; but this motion being rejected, he was removed to Ely House, in Holborn, where he died in the year 1647. Farnabie was a very eminent grammarian; and many writers have spoken with great approbation of his labours. Mr Bayle in particular says, "His notes upon most of the ancient Latin poets have been of very great use to young beginners; being short, learned, and designed chiefly to clear up the text."

FARNHAM, a market-town at the western end of the county of Surrey, in the hundred of the same name, 41 miles from London, on the road to Portsmouth. The vicinity is chiefly remarkable for the quality of the hops produced, which by their celebrity, and consequently high price, have extended the cultivation very considerably. There is an ancient castle transformed into a palace, the residence of the Bishop of Winchester. The making of worsted hose, which once flourished, has now disappeared. The market is held on Thursday, and the sale of wheat at it is extensive. The population amounted in 1801 to 2508, in 1811 to 2911, in 1821 to 3132, and in 1831 to 3142.

FARNOVIANS, in *Ecclesiastical History*, a sect of Socinians, so called from Stanislaus Farnovius, who separated from the other Unitarians in the year 1568, and was followed by several persons eminent for their learning. This sect did not last long; for having lost their chief, who died in 1615, it was scattered abroad and reduced to nothing. Farnovius was engaged by Gonesius to prefer the Arian system to that of the Socinians; and consequently asserted that Christ had been produced out of nothing by the Supreme Being, before the creation of this terrestrial globe. His sentiments concerning the Holy Ghost are not certainly known; but it appears that he warned his disciples against paying the tribute of religious worship to the Divine Spirit.

FARNWORTH, a township of the county of Lancaster, within the parish of Dean, occupied chiefly by manufacturers of cotton goods, whose numbers amounted in 1801 to 1439, in 1811 to 1798, in 1821 to 2044, and in 1831 to 2928.

FARO, a city on the sea coast, in the province of Algarve, in Portugal, in lat. 37. 2. N. It is a little to the westward of Cape Santa Maria, and only admits ships to enter or depart at spring tides. It has some trade with the north of Europe, to which it exports figs, resins, oranges, lemons, olives, and almonds, cork, sumach, and ropes and cords of esparto and the tunny fish. The streets of this town are broad and regularly built, and it contains a cathedral, 927 houses, and 6025 inhabitants.

FAROE, Faroer, or Feroe, a group of European islands, situated in the Northern Ocean, between Zetland and Iceland, about 200 miles north-west of the former. They appear to form the country described by the early Venetian navigators under the name of Friesland, though that term was afterwards applied by the English to the northern extremity of Greenland. These islands are twenty-two in number, of which the principal are Stromoe, Osteroe, Suderoe, Wangoe, and Sandoe. They consist throughout of rocks and hills, rising to a considerable height, and separated from each other by narrow valleys, or rather ravines. Although, however, these hills rise abruptly, there are often on their summits, or at different stages of their ascent, plains of considerable magnitude. They everywhere present to the sea perpendicular cliffs, broken into a thousand fantastic forms, and which, to those who sail along the coast, present at every turn the most picturesque and varied scenery. The highest peak is that of Skellingfell, in the island of Stromoe, which is supposed to rise about 3000 feet above the sea. The rocks consist generally of trap, and exhibit little variety of composition, though they present some striking geological phenomena. The zeolites and chalcedonies here collected have long supplied the best specimens of these minerals to the cabinets of Europe.

The population of the Faroe Islands, according to a statistical table drawn up in 1812, amounted to 5209. Agriculture is in a very imperfect state, the infield, or cultivated land, being supposed to bear to the outfield, or uncultivated, the proportion of one to sixty. The plough is scarcely ever used, being in fact ill suited to the rugged and uneven surface of which all the islands consist. The ground is therefore turned up with the spade, care being taken not to destroy the roots of the grass. Horses and cows are few in number, and the latter give very little milk, in consequence, probably, of the very coarse hay upon which they are fed. Sheep form the chief riches of the islanders, and the number possessed by them was calculated in 1812 at 35,307. Some individuals have flocks of two or three hundred. These sheep are allowed to run about, both in summer and winter, without ever being housed, and in severe seasons they suffer considerably. The wool is generally coarse, and is torn off the animals in so rough a manner, as often to lacerate the skin. The fishery, which was once considerable, has been neglected, and is now of little consequence. The catching of the numerous birds which build their nests upon the face of the cliffs, forms a great source of subsistence to the inhabitants. Those persons employed in this hazardous trade display great ingenuity and the most adventurous spirit. Sometimes the fowler is let down from the top of the cliff by a rope fastened to his waist; at other times, where there is any footing at all, he climbs the steepest rocks, or, where that is impossible, has himself thrust up by poles made for the purpose. The puffin (*Alca Arctica*) is the most common of these birds, and the eider duck is here often shot for food.

The Danish government has given the monopoly of the trade of the Faroe Islands to a mercantile house at Copenhagen, under the condition of supplying the inhabitants with a sufficient quantity of grain at a constant fixed price. Should the market price be such as to render this a losing transaction, the merchant is indemnified by government. This care of provisioning the islands is probably superfluous; and the natural bad effects of a monopoly are felt in the high price of other imported articles, a good jacket being often given for a few leaves of tobacco. The exports consist of hose knit on the islands, to the annual amount of 100,000 pairs; tallow, fish, train-oil, feathers, skins, and butter. During the war between Britain and Denmark, the Fort of Thorshaun was, in 1808, destroyed by Captain Baugh, lest it should afford harbour to privateers. A German adventurer, who assumed the name of Baron Hompesch, afterwards landed and plundered the place; but his conduct was disavowed by the British government, who even restored the value of the property of which the natives had been robbed. Finding also, that the people having lost their communication with Denmark, were in danger of suffering from famine, Britain permitted a limited intercourse to be carried on, under license, from Leith. But the peace restored all things to their usual channel.

Thorshaun, the principal place in the country, does not contain above 520 inhabitants. It is situated on the eastern coast of the island of Stromoe, upon a narrow tongue of land, having creeks on each side, where ships may be safely moored. The houses are built of wood, and roofed with birch bark covered with turf; the greenness of which makes it impossible, at a very short distance, to distinguish the place from the surrounding fields. The character of the people is generally marked by great simplicity of manners, kindness, and hospitality. (See *A Description of the Faroe Islands;* by the Rev. G. Landt; translated from the Danish; London, 1810. *An Account of some Geological Facts observed in the Faroe Islands;* by Sir George Stewart Mackenzie, Bart. in the *Transactions of the Royal Society of Edin.* vol. vii. *An Account of the Mineralogy of the Faroe Islands;* by Thomas Allan, Esq. *ibid.*)

FARQUHAR, George, a celebrated comic writer, was the son of a clergyman, and born in 1678 at Londonderry, in Ireland, where he received the rudiments of his education, and gave early indications of that genius for which he afterwards distinguished himself. As he was one of a numerous family, his parents, having no fortune to leave to their children, resolved to give him the compensatory benefit of a liberal education; and, with this view, young Farquhar, as soon as he was qualified for the university, was sent to Trinity College, Dublin. This took place in 1694. At first our youth Farquhar made great progress in his studies, and even acquired considerable reputation; but at length the retirement and restraint of a college life proving distasteful to him, he quitted Trinity, where he found himself incapable of seeking advancement by the slow and regular progression of university degrees; and betaking himself to the stage, he obtained admission into the company of the Dublin theatre. Though his voice was somewhat weak, he had the advantage of a good person, which, with his evident talents, ensured him a favourable reception as an actor; and he resolved to continue on the boards until something better should present itself for his acceptance. But an accident of rather a serious kind put an end to this resolution, and suddenly altered the whole complexion of his life. Being to play the part of Guyomar in Dryden's *Indian Emperor,* and having forgotten to blunt his sword, or exchange it for a theatrical rapier, Farquhar, in the scene where Guyomar is supposed to kill the Spanish general Vasquez, run through the body his brother tragedian who represented that part. The poor general of the scene believed himself killed in good earnest, but happily the wound, though dangerous, did not prove mortal. Farquhar, however, was so shocked at the occurrence, that he quitted the stage, determined never again to expose himself to the risk of such accidents. But this histrionic essay had been sufficient to form his taste and develope his talents for dramatic literature.

Having now no inducement to remain at Dublin, Farquhar proceeded to London, where, in 1696, Wilks the actor, knowing his humour and abilities, prevailed on him to write a play, at the same time assuring him that he was generally considered as better qualified to furnish compositions for the stage than to act a part in those of other writers. His first comedy, called *Love in a Bottle*, was brought out in 1698, and well received, on account of its sprightly dialogue and busy scenes. About this time the Earl of Orrery, to whom Farquhar was already known by his literary talents, and esteemed for his character, gave him a commission as lieutenant in his own regiment, then in Ireland, in which capacity he served several years, and gave proofs both of courage and conduct. In 1700 he produced his *Constant Couple, or Trip to the Jubilee*, so called because it was then the jubilee year at Rome, whither persons of all countries flocked for indulgences and amusements. In Sir Harry Wildair he delineated a gay and airy character, so impregnated with wit and vivacity, and withal so well adapted to the peculiar talents of Wilks, that the player acquired almost as much reputation as the dramatist. Towards the close of this year Farquhar visited Holland, probably in his military capacity, and, in several letters which he wrote, gave a very humorous description of the people, and the adventures he met with, particularly of an entertainment given by the Earl of Westmoreland, whilst not only that nobleman himself, but King William and others, were detained by a violent storm. In 1701 he was a spectator, if not a mourner, at the funeral of Dryden. Encouraged by the success of his *Constant Couple*, he this year wrote a continuation of the play, called *Sir Harry Wildair, or the Sequel of the Trip to the Jubilee*, in which Mrs Oldfield, whom the author had introduced to the stage, was as greatly admired, and obtained as much reputation, in her part, as Wilks had previously done in his.

In 1702 he published his *Miscellanies*, consisting of poems, letters, and essays, all filled with humorous and pleasant sallies. Some of these letters were, it is said, published from copies returned at his request by Mrs Oldfield, to whom they had been addressed. At the end there is a *Discourse upon Comedy*, in reference to the English stage; and one of the letters contains *The Picture*, a descriptive character of the writer, in which he is represented as an ingenious, good-natured, and thoughtless person. In 1703 he brought out another comedy, entitled *The Inconstant, or the Way to win him;* but as the public taste, influenced by fashion, was now turning in favour of French and Italian operas, which have long been the bane of our native genius, this production, though not inferior in merit, was more coldly received than any of its predecessors. This year Farquhar married (as he was led to believe) a person of fortune. The lady, it seems, had fallen violently in love with him, and resolved to have him at any rate; but, knowing his habits, and aware that he was too dissipated to think of matrimony unless advantages were annexed to it, she caused a report to be circulated that she had a great fortune, and followed this up by an intimation of her love for the dramatist. Farquhar fell into the snare, and married her. But although he found himself grossly deceived, his circumstances embarrassed, and his family increasing, he, with rare magnanimity, never once upbraided his wife with the imposition she had practised on him, but behaved to her with all the delicacy and tenderness of a kind and indulgent husband.

Early in 1704, Farquhar, in conjunction with another person, produced a farce called *The Stage-coach*, which was well received. His comedy entitled *The Twin Rivals* was played in 1705, and *The Recruiting Officer* made its appearance in 1706. His last production, *The Beaux Stratagem*, was only performed a few days before his death, which happened in April 1707, but not until he had been made aware of the complete success of the comedy. *The Beaux Stratagem* is generally regarded as Farquhar's masterpiece, and, certainly, of all his plays it is that which has kept the firmest hold of the stage. The characters are said to have been drawn from living originals whom the author met with in Lichfield and its vicinity; but whether this was the case or not, he has sufficiently generalized his delineations to divest them of partial or localized distinctions, and has thus imparted to them an interest which neither time nor change of manners has in any material degree impaired. Towards the close of his life Farquhar was unhappily oppressed with debt, which obliged him to sell his commission; a circumstance which, with some collateral disappointments, preyed upon his spirits, and hurried him to a premature grave before he had attained the age of thirty. Soon after his death, the following letter, addressed to Mr Wilks the actor, was found amongst his papers: "Dear Bob, I have not any thing to leave thee to perpetuate my memory but two helpless girls; look upon them sometimes, and think of him that was to the last moment of his life, thine, George Farquhar." This affecting recommendation, resembling the testament of Eudamidas, was not lost on the generous player, who watched over the orphans of his gifted friend, and, when they came of age to be put out in the world, procured each of them a benefit to supply the means necessary for the purpose.

Of Farquhar's merits as a dramatic writer various opinions have been entertained, and different judgments consequently pronounced. It can scarcely be disputed, however, that he was commonly fortunate in the choice of his subjects, which he embellished with a great variety of characters and incidents; that his style is in general simple, unaffected, and natural; that his dialogue is full of gaiety and wit, and flows in a natural, easy current, less sparkling and brilliant than that of Congreve, but at the same time also less elaborate; and that his plots, though almost all founded on improbable or romantic suppositions, are naturally conducted, and full of amusing vivacity. He has been justly reproached with licentiousness, which, in his discourse upon comedy, he even attempts to defend; but this was the vice of the age rather than of the writer, who felt himself obliged to consult its taste, and adapt his compositions to its prevailing manners; and is certainly not less imputable to Congreve than to Farquhar. The tone of their characters, indeed, appears to have been that of the society of the time, of which these are, as it were, reflections; and hence in the comedies of both there is a relative truth, which must not be lost sight of in estimating the moral qualities of their works. The manners represented are no doubt detestable, and vice appears rampant and unblushing, without the mask of hypocrisy, which, in less degenerate times, she is compelled to assume as a reluctant homage to virtue; but these manners are real, not imaginary; and it is from such delineations alone that we can acquire accurate conceptions of the true spirit and character of the age when they were relished and applauded. Pope, it seems, used pettishly to stigmatize Farquhar as a mere farce-writer. But posterity has been more just to his merits than the Wasp of Twickenham; and his productions, with all their faults, still keep their place on the stage, and are likely to do so, as long as the redeeming attributes of wit and genius possess any attraction in scenic representation.

FARRIER, one whose employment it is to shoe horses, and cure them when diseased or lame. The term *farrier* is probably a corruption of *ferrier*, in French *ferrans*, from the verb *ferrer*, to shoe a horse; all these words being derived from the Latin *ferrum*, iron. There is no doubt that the word *farrier* was at first used to denote a person who shod horses; but as persons of this description were for a long period the only *horse-doctors*, the term was soon used in the more extensive sense of *horse-doctor* or *horse-leech;* and hence *farriery* came to signify the *art of curing the diseases of horses.*

There can be little doubt that the word *farrier* was originally spelt *ferrier* or *ferrer*, as we meet with this latter orthography in some of our older writers. Thus Blundeville, who wrote in the time of Queen Elizabeth, in his Address to the Gentlemen of England, book fourth, has the following sentence: "All horses, for the most part, do come into their decay sooner than they should do, by one of these four waies; that is to say, either for lacke of being well bred, or through the rashness of the rider, the negligence of the keeper, or else through the unskilfulnesse of the *ferrer.*" Again, the same author mentions "Martin Ghelly of Aston, called Martin Alman, chiefe *ferrer* to the queen's magistie."

Farriery, in the usual acceptation of the word, forms only a part of the more general art, which has been commonly called the *veterinary art*, by which is understood the art of medicine as applied to the inferior animals, an art which has been long called by the French *l'art vétérinaire*, or *médicine vétérinaire.* This word *veterinary* is of very ancient date, being derived from the Latin *veterinarius*, which is used by Columella to denote a *horse-doctor* or *cattle-doctor.* The term *veterinary*, being derived from *veterinus*, a softened and abbreviated form of *veheterinus*, *à vehendo*, *carrying*, is properly applicable only to beasts of burden; but *veterinary medicine* is now commonly employed in a more comprehensive sense, to denote the art of curing the diseases of *domestic animals* in general. See VETERINARY MEDICINE.

FARRINGDON, a market-town of the county of Berks, in the hundred of the same name, sixty-eight miles from London. It is finely situated on the declivity of the termination of a range of hills, at the foot of which the Thames runs, and where the ruins of an ancient castle are to be seen. It is a town of but little trade, except what arises from a good market held on Tuesday. The inhabitants amounted in 1801 to 1691, in 1811 to 1843, in 1821 to 2784, and in 1831 to 2729.

FARS, a province of Persia, bounded by Irak on the north, Kerman and Laristan on the east, Kuzistan on the west, and on the south by the Persian Gulf. This province is divided into the Germaseer and Sirhud, or the warm and the cold climates. It is in general sandy and barren, though with some considerable exceptions. The Tabris, formed by the junction, within a few miles of the town of Zeitoon, of two streams which take their rise in the mountains of Fars, is the most considerable river of the province. It divides Fars from Kuzistan, and, eight miles below the town of Endian, falls into the sea. The warm region of this district extends from the sea to the latitude of Kazeroon, and runs parallel with the gulf from the banks of the Tabris to the confines of Laristan. It is chiefly a sandy plain at the foot of the mountains, the cultivation of which depends on the periodical rains; and when these prove abundant, the country yields abundance of dry grain; but when the rains fail, which too frequently happens, a famine generally ensues. The sandy plain, or the Dushtistan as it is called, is divided into two districts, which are separated by the projecting mountain of Bung. These two districts are thinly peopled and badly cultivated; and the few mud villages which are scattered over the plain bespeak but too clearly the wretchedness and poverty of their possessors. The cold region comprehends most of the mountainous part of Fars, extending from the latitude of Kazeroon to that of the town of Yezdekhast, situated on the bed of what appears to have been formerly a river, which separates this province from Irak. The mountains are here intersected by plains, which seldom exceed eight or ten miles in breadth, whilst in length they vary from fifteen to a hundred. They are in general fertile, affording abundance of pasturage; nor are they so deficient in water as they have sometimes been represented. A few of them, such as those of Shiraz, Kazeroon, and Merdesht, are tolerably well cultivated. But they are for the most part, particularly to the northward and westward, destitute of inhabitants. It is mentioned by Kinneir, in his Geographical Memoir of the Persian Empire, that in 1809 he travelled in this country "through the most delightful valleys, covered with wood and verdure," but all was solitary, nor was the face of a human being anywhere to be seen. The country, it appears, had been possessed by a predatory tribe, who, in consequence of their licentious conduct, had been extirpated by the vengeance of the prince, and who having in consequence fled to the lofty and inaccessible mountains, lived there on the scanty fare of a sort of bread afforded by acorns, and thence sallying forth on the low country beneath, robbed and plundered the unwary traveller, sometimes extending their inroads to villages, the inhabitants of which they either murdered, or carried away captive, to be sold for slaves in an unknown and distant land. The face of the country in the eastern parts of Fars is somewhat different, being open, the plains of greater extent, and of a sandy soil, where water is not so plentiful. The great range of mountains seen from the coast is a mere elongation of the chain of Mount Tagros, which extends in a continued succession of ridges from the borders of the Persian Gulf to the Caspian Sea and the Caucasus. These hills in Fars are situated at different distances from the sea. At Bushire they are distant twenty-four miles. But towards Bunder Reig the plain becomes contracted; and a low ridge, known by the name of Kohi Bung, or the hill of Bung, and about seven or eight miles broad, suddenly projects to the south, and touching the sea, separates the district of Leerawee from that of Hiadouat. Beyond this hill, at the plain of Leerawee, the mountains are about twenty miles distant from the sea, at which distance they continue for eighteen or nineteen miles, when they again approach the south; and this branch is known by the name of Zeitoon, on turning the southern point of which they again abruptly retire to the northward; and at the port of Mashoor they are thirty miles from the sea. The principal towns of the province are Shiraz, the capital, with 40,000 inhabitants; Bushire, the chief port in the Persian Gulf; Darabjerb, Bebahan, and some others. Within its confines also are the ruins of the cities of Shapoor and Persepolis; the latter containing some magnificent remains of antiquity.

FARTACH, or FARTAK, a sea-port of Arabia, in the province of Hadramaut, belonging to the sheik of Keshun. It is 133 miles south-east of Hadramaut, and 480 east of Mocha.

FARTHING, a small English copper coin, amounting to one-fourth of a penny. It was anciently called *fourthing*, as being the fourth of the integer or penny.

Farthing of Gold, a coin used in ancient times, containing in value the fourth part of a noble, or 20d. in silver. It is mentioned in the statute 9 Henry V. cap. 7, where it is enacted that there shall be good and just weight of the noble, half noble, and farthing of gold.

Farthing of Land seems to differ from *farding-deal* For in a survey-book of the name of West Hapton, in Devonshire, there is an entry thus: A. B. holds six farthings of land at L.126 per annum. So that the farthing of land must have been a considerable quantity, indeed far more than a rood.

FASCES, in Roman antiquity, axes bound together with rods or staves, and borne before the Roman magistrates as a badge of their office and authority. According to Florus, the use of the fasces was introduced by the elder Tarquin, the fifth king of Rome; and they were then the mark of the sovereign dignity. In after times they were borne before the consuls by turns, who had each twelve, borne by as many lictors. These fasces consisted of branches of elm, with a *securis* or axe in the middle, the head of which projected beyond the rest. But Publicola took the axe out of the fasces, as Plutarch assures us, in order to remove all occasion of terror. After the consuls, the prætors assumed the fasces. In the government of the decemvirs, it was the practice at first for only one of their number to have the fasces borne before them; but afterwards each had twelve, after the manner of the kings. When the magistrates, who by right had the axes carried before them, intended to show deference to the people, or some person of singular merit, they either sent away the lictors, or commanded them to lower the fasces, which was denominated *submittere fasces*. Many instances of this occur in Roman history.

FASCETS, in the art of making glass, are the irons thrust into the mouths of bottles, in order to convey them to the annealing tower.

FASCIA, in *Antiquity*, a thin sash which the Roman women wrapped round their bodies next to the skin, in order to make them slender. Something of this sort seems also to have been in use amongst the Grecian ladies.

Fascia, in *Architecture*, signifies any flat member having considerable breadth and but small projection, as the band of an architrave, larmier, and the like. In brick buildings, the juttings out of the brick beyond the windows in the several stories except the highest are called *fascias* or *fasciæ*.

FASCINATION, from the Greek βασκαινειν, to *fascinate* or *bewitch*, a sort of witchcraft supposed to operate either by the eye or the tongue. Ancient writers distinguish two sorts of fascination; one performed by looking, or the efficacy of the eye, and the other by words, especially by malignant praises.

Fascination of serpents, a faculty which these animals are supposed to possess of attracting birds from the air, and making prey of them.

FASCINES, in *Fortification*, are a kind of faggots made of small branches of trees or brushwood, tied in three, four, five, or even six places, and are of various dimensions, according to the purposes to which they are to be applied. Those which are to be pitched over, for burning lodgments, galleries, or any other works of the enemy, should be one and a half or two feet in length; but those which are intended to form epaulements or chandeliers, to raise or fill up ditches, are made from six to ten feet in length, and from one foot to one and a fourth in thickness. Fascines are made in the following manner: Six small pickets are stuck into the ground, two and two, forming little crosses well fastened in the middle with willow bindings; on these trestles the branches are laid, and bound round with withes at every two feet. Six men are employed in making a fascine; two cut the boughs, two gather them, and the remaining two bind them. These six men can make twelve fascines every hour.

FAST, in general, denotes abstinence from food; but is more particularly used for such abstinence on a religious account.

Religious fasting has been practised by most nations from the remotest antiquity. Some divines even pretend that it had its origin in the earthly paradise, where our first parents were forbidden to eat of the tree of knowledge. But though this seems carrying the matter too far, it is certain that the Jewish church has observed fasts ever since its first institution. Nor were the neighbouring nations, the Egyptians, Phœnicians, and Assyrians, without their fasts. The Egyptians, according to Herodotus, sacrificed a cow to Isis, after having prepared themselves by fasting and prayer; a custom which he likewise ascribes to the women of Cyrene. Porphyry affirms, that the Egyptians, before their stated sacrifices, always rested a number of days, sometimes even of weeks; and that during this time the priests and devotees not only abstained from flesh, fish, wine, and oil, but even from bread, and some kinds of pulse. These austerities were communicated by them to the Greeks, who observed their fasts much in the same manner. The Athenians had the Eleusinian and Thesmophorian fasts, the observance of which was very rigorous, especially amongst the women, who spent one whole day sitting on the ground in a mournful dress, without taking any nourishment. In the island of Crete, the priests of Jupiter were obliged to abstain during their whole lives from fish, flesh, and baked meats. Apuleius informs us, that whoever had a mind to be initiated in the mysteries of Cybele was obliged to prepare himself by fasting ten days; and, indeed, all the pagan deities, whether male or female, required this duty of those who desired to be initiated into their mysteries, of the priests and priestesses who gave out the oracles, and of those who came to consult them.

Amongst the heathens fasting was also practised before some of their military enterprises. Aristotle informs us, that the Lacedæmonians having resolved to succour a city of the allies, ordained a fast throughout the whole extent of their dominions, without excepting even the domestic animals; and this they did for two ends, first, to spare provisions in favour of the besieged, and, secondly, to draw down the blessing of heaven upon their enterprise. The inhabitants of Tarentum, when besieged by the Romans, demanded succours from their neighbours of Rhegium, who immediately commanded a fast throughout their whole territories. Their enterprise having proved successful by throwing a supply of provisions into the town, the Romans were obliged to raise the siege; and the Tarentines, in memory of this deliverance, instituted a fast to be annually observed ever afterwards.

Fasting has always been reckoned a particular duty amongst philosophers and religious people, some of whom have carried their abstinence to an incredible length. At Rome it was practised both by kings and emperors. Numa Pompilius, Julius Cæsar, Augustus, Vespasian, and others, we are told, observed stated fasts; and Julian surnamed the Apostate was so exact in this observance as to outdo the priests themselves, and even the most rigid philosophers. The Pythagoreans kept a continual lent; but with this difference, that they believed the use of fish to be equally unlawful with that of flesh. Besides their constant temperance, they also frequently fasted rigidly for a considerable time. In this respect, however, they were all outdone by their master Pythagoras, who continued his fasts for no less than fifty days together. Even Apollonius Tyaneus, one of his most celebrated disciples, could never equal him in the length of his fasts, though these greatly exceeded those of the ordinary Pythagoreans. The Gymnosophists, or Brahmins of the East, are also very remarkable for their severe fastings; and the Chinese, according to Father Lecomte, have likewise their stated fasts, with forms of prayer, for preserving them from barrenness, inundations, earthquakes, and other calamities. The Mahommedans too, who possess so large a part of Asia, are very remarkable for the strict observance of fasts; and the exactness of their dervises in this respect is extraordinary.

Fasting was often used by the heathens for superstitious purposes; sometimes to procure the interpretation of dreams; at others, to serve as an antidote against the pernicious consequences of nocturnal visions. The Jews, though expressly forbidden to fast upon Sabbath days, think themselves at liberty to dispense with this duty when they happen the night preceding to have had frightful and unlucky dreams, which they consider as presaging great misfortunes. On these occasions they observe a formal fast during the whole day; and at night the patient, having invited three of his friends, addresses himself to them seven times in a very solemn manner, saying, "May the dream I have had prove a lucky one;" and his friends answer as many times, "Amen, may it be lucky, and God make it so;" after which, in order to encourage him, they conclude the ceremony with the words of Ecclesiastes, "Go eat thy bread with joy," and then set themselves down to table. They have also added several fasts not commanded in the law of Moses, particularly three, in memory of sore distresses which their nation has at different times suffered. The abstinence of the ancient Jews commonly lasted twenty-seven or twenty-eight hours at a time, beginning before sunset, and not ending till some hours after sunset the next day. On these days they were obliged to wear white robes in token of grief and repentance, to cover themselves with sackloth, or their worst clothes, to lie on ashes, to sprinkle these on their heads, and to perform other like ceremonies. Some spent the whole night and day following in the temple or synagogue, in prayers and other devotions, barefooted, with a scourge in their hands, of which they sometimes made a good use, in order to excite their zeal. Lastly, to complete their abstinence, they were accustomed at night to eat nothing but a little bread dipped in water, with some salt for seasoning; except indeed they chose to add to their repast some bitter herbs and pulse.

The ancients, both Jews and Pagans, had also their fasts for purifying the body, particularly the priests and such as were any way employed at the altars; for when nocturnal disorders happened to them, it was unlawful to approach the altars all the next day, which they were bound to employ in purifying themselves. On this account, at great festivals, where their ministry could not be dispensed with, it was usual for them, on the eve of these solemn occasions, not only to fast, but also, for the greater certainty, to abstain from sleep. For this purpose the high priest had under officers to awake him, if overtaken with sleep, against which other preventives were also employed.

FASTERMANS, or Fasting-men, was used in our ancient customs to signify men of repute and substance; or rather pledges, sureties, or bondsmen, who, according to the Saxon polity, were bound fast to answer for one another's peaceable behaviour.

FASTI, in Roman antiquity, the kalendar in which were expressed the several days of the year, with their feasts, games, and other ceremonies.

There were two kinds of *fasti*, the greater and less; the former being distinguished by the appellation of *fasti magistrales*, and the latter by that of *fasti kalendares*. The *fasti kalendares*, which were properly and primarily called *fasti*, are defined by Festus Pompeius to be books containing a description of the whole year, that is, ephemerides, or diaries, in which the several kinds of days, *festi*, *profesti*, and *fasti*, *nefasti*, are distinguished. The author of these was Numa, who committed the care and direction of the *fasti* to the *pontifex maximus*, whom the people used to consult on every occasion. This custom continued until the year of Rome 450, when C. Flavius, secretary to the pontifices, exposed in the forum a list of all the days on which it was lawful to work; and this proved so acceptable to the people, that they made him curule ædile. The *fasti kalendares* were of two kinds, namely, *urbani* and *rustici*. The *fasti urbani*, or *fasti* of the city, were those which obtained or were observed in the city. Some are of opinion that they were thus called, because they were exposed publicly in different parts of the city; though from the various inscriptions of this kind upon antique stones, it may be conjectured that private persons had likewise *fasti* in their houses. Ovid undertook to illustrate these *fasti urbani*, and comment on them, in his *Libri Fastorum*, of which the first six books are still extant; the last six, if they were ever written, being now lost. In the *fasti rustici*, or country *fasti*, were expressed the several days, feasts, and the like, to be observed by the country people. For as the latter were occupied in tilling the ground, fewer feasts, sacrifices, ceremonies, and holidays, were enjoined on them than on the inhabitants of cities; and they had also some peculiar ones not observed at Rome. These rustic *fasti* contained little more than the ceremonies of the kalends, nones, and ides; the fairs, signs of the zodiac, increase and decrease of the days, the tutelary gods of each month, and certain directions for rustic labours to be performed each month. In the greater fasti, or *fasti magistrales*, were expressed the several feasts, with every thing relating to the gods, religion, and the magistrates; the emperors, their birthdays, offices, days consecrated to them, with feasts and ceremonies established in their honour, or for their prosperity. When flattery had at length swelled the *fasti* with a number of such circumstances, they came to be denominated *magni*, in order to distinguish them from the bare kalendar, or *fasti kalendares*.

Fasti was also a chronicle or register of time, in which the several years were denoted by the respective consuls, with the principal events which happened during their consulates. This register was denominated *fasti consulares*, or the consular *fasti*.

Fasti, or *Dies Fasti*, likewise denoted court days. The word *fasti*, *fastorum*, is formed from the verb *fari*, to speak, because during those days the courts were opened, causes might be heard, and the prætor was allowed *fari*, to pronounce the three words, *do*, *dico*, *addico*. The days in which this was prohibited were called *nefasti*.

The *dies fasti* were noted in the kalendar by the letter *F;* but it is to be observed that there were some days *ex parte fasti*, partly *fasti*, partly *nefasti*, in which justice might be distributed at certain times of the day, and not at others. These days were called *intercisi*, and were marked in the kalendar by the letters *F. P. fastos primo*, in which justice might be demanded during the first part of that day.

FASTOLF, Sir John, a renowned English officer, who served in France under Henry IV., Henry V., and Henry VI., was descended from an ancient family in Norfolk, and was born about the year 1377. He was as much distinguished for his virtue at home, as for his valour abroad; and became no less amiable in his private than he had been admired in his public character. He died in 1457, being then upwards of eighty years of age, as we learn from his contemporary William Caxton, the first English printer. By an unaccountable mistake it has been asserted, that Shakspeare's Falstaff was drawn in order to ridicule Fastolf; and this circumstance has made judicious biographers the more studious to vindicate his reputation.

FAT, an oily concrete substance, deposited in different parts of animal bodies.

Fat, in nautical language, signifies the same with broad. Thus a ship is said to have a fat quarter, if the trussing in or tuck of her quarter be deep.

Fat likewise denotes an uncertain measure of capacity. Thus a fat of isinglass contains from three and a fourth hundredweight to four hundredweight; a fat of unbound books, half a maund or four bales; of wire, from twenty to twenty-five hundredweight; and of yarn, from 220 to 221 bundles.

Fat, or Vat, is also applied to several utensils; as, a great wooden vessel, employed for measuring of malt, and containing a quarter or eight bushels; a large brewing vessel, used by brewers to run their wort in; and a leaden pan or vessel for making salt at Droitwich.

FATA Morgana, a very singular phenomenon, mentioned by different philosophical writers and travellers, who inform us that it is seen in the Straits of Messina, and sometimes denominated the *Castles of the Fairy Morgana*. The accounts of this phenomenon differ considerably from one another, and travellers are not agreed as to the causes of its production.

Minasi, in his dissertation on the *Fata Morgana*, gives a description of this remarkable phenomenon. When the rising sun shines from that point whence its incident ray forms an angle of 45° on the Sea of Reggio, and the bright surface of the water in the bay is not disturbed either by the wind or the current, whilst the spectator is placed on an eminence, with his back to the sun and his face to the sea, there appear on a sudden in the water, as in a catoptric theatre, multiplied objects, numberless series of pilasters, arches, castles well delineated, regular columns, lofty towers, superb palaces, with balconies and windows, extended alleys of trees, delightful plains with herds and flocks, armies of men on foot and horseback, and many other strange images, in their natural colours and proper actions, passing rapidly in succession along the surface of the sea during the whole of the short period of time that the above-mentioned circumstances remain as described. But if, in addition to these circumstances, the atmosphere be highly impregnated with vapour and dense exhalations, not previously dispersed by the action of the wind or waves, or rarefied by the sun, it then happens that in this vapour, as in a curtain extended along the channel to the height of from fifteen to twenty feet, and nearly down to the sea, the same objects are beheld not only reflected from the surface of the sea, but likewise in the air, though not so distinct or well defined as the former objects from the sea.

If the air be slightly hazy and opake, and at the same time dewy and adapted to form the iris, then the above-mentioned objects will appear only at the surface of the sea, as in the first case, but all vividly coloured, or fringed with red, green, blue, and other prismatic colours.

From this account, then, it appears, that there are three different species of *Fata Morgana*; the first, that which appears at the surface of the sea, being denominated the *Marine Morgana*; the second, that which is seen in the air, called the *Aerial Morgana*; and the third, that which is observed only at the surface of the sea, being the *Morgana* fringed with prismatic colours. Minasi has attempted to trace the etymology of the word *Morgana*, which, he thinks, is derived from μωρος, *tristis*, and γανοω, *lætitia afficio*. This splendid sight affects all descriptions of men with such joy, that they run towards the sea, exclaiming *Morgana, Morgana*. The etymology of Minasi, therefore, though it may at first view seem to be a contradiction in terms, will appear not unnatural, when, besides the joy which the Morgana inspires, we take into account the corresponding sorrow or dejection which must be felt when it vanishes away. The same author informs us, that he beheld this magnificent appearance three times, and would rather behold it again than the most superb theatrical exhibition in the world.

In his physical and astronomical remarks on this phenomenon, Minasi observes that the sea in the Straits of Messina exhibits the appearance of a large inclined speculum; that, in the alternate current or tide which flows and returns in the straits six hours each way, and is constantly attended by an opposite current along shore to the medium distance of about half a league, there are many eddies and irregularities at the time of the change of its direction; and that the Morgana usually appears at this period. He ascribes the effects produced by it to the supposed inclination of the surface of the sea, and its subdivision into different planes by the contrary eddies; and the effects produced in the air he considers as the result of saline and other effluvia suspended in the air. These appearances are produced by a calm sea, and one or more strata of superincumbent air differing in refractive, and consequently in reflective power, rather than from any considerable change in the surface of the water, with the laws of which we are much better acquainted than with those of the atmosphere.

To this account may be added that given by Houel, whose judgment and accuracy render his authority highly respectable. In fine summer days, says he, when the weather is calm, there arises above the great current a vapour, which acquires a certain density, so as to form in the atmosphere horizontal prisms, the sides of which are disposed in such a manner, that when they come to their proper degree of perfection, they reflect and represent successively, for some time, like a moveable mirror, the objects on the coast or in the adjacent country. They exhibit by turns the city and suburbs of Messina, trees, animals, men, and mountains; and are certainly beautiful aerial moving pictures. There are sometimes two or three prisms, equally perfect; and they continue in this state from eight to ten minutes. After this, some shining inequalities are observed upon the surface of the prism, which render confused to the eye the objects which had before been so accurately delineated, and the picture vanishes. The vapour forms other combinations, and is dispersed in air. Different accounts have been given of this singular appearance, which may perhaps be attributed to a bitumen which issues from certain rocks at the bottom of the sea, and is often seen to cover part of its surface in the Straits of Messina. The subtile parts of the bitumen being attenuated, combined, and exhaled with the aqueous globules which are raised by the air, and formed into bodies of vapour, give to this condensed vapour more consistence, and contribute, by their smooth and polished particles, to the formation of a kind of aerial crystal, which receives the light, reflects it to the eye, and transmits to it all the luminous points which colour the objects exhibited in this phenomenon, and render them visible.

FATE (*fatum*), denotes an inevitable necessity depending upon a superior cause. The word is formed *a fando*, from speaking, and primarily implies the same with *effatum*, a word or decree pronounced by God, or a fixed sentence by which the Deity has prescribed the order of things, and allotted to every person what shall befal him. The Greeks called it ειμαρμενη, as if it were a chain or series of things indissolubly linked together.

The term is also used to express a certain unavoidable destination of things, by which all agents, voluntary as well as necessary, are swayed and directed to prescribed ends. In this last sense, fate is distinguished into astrological, arising from the influence and position of the heavenly bodies, which, it was supposed, gave laws both to the elements and mixed bodies, and to the wills of men; and Stoical, defined by Cicero an order or series of causes, in which cause being linked to cause, one produces another, and thus all things flow from one prime first cause. To this fate the Stoics subject even the gods. But fate is divided by later authors into physical and divine. Physical fate is an order and series of natural causes, with their consequent effects; and the results of it are all the events and phenomena of nature. Divine fate is what is more usually called *Providence.*

FATESCH, one of the circles into which the Russian province of Kursk is divided. It is a district fertile in corn, watered by the Usoscha, and contains about 46,000 inhabitants. The chief place is of the same name, and has a population of 2450 persons. It is situated in long. 37. 5. E. and lat. 52. 20. N.

FATHEMITES, Fathimites, or Fatimites, the descendants of the prophet Mahommed by Fathema, or Fatima, his daughter.

FATHER, a term of relation denoting a person who has begotten a child. By the laws of Romulus, a father had an unlimited power over his children. Amongst the Lacedæmonians, as we learn from Aristotle's *Politics,* the father of three children was excused from the duty of mounting guard for the security of the city; and the father of four children was exempted from every public burden. The Poppæan law, amongst the Romans, granted many valuable privileges to the father of three children, one of which was, that he should be excused from civil offices, and that the mother should have liberty, in her father's lifetime, to make a will, and manage her estate without the authority of tutors.

Natural Father is he who has illegitimate children.

Adoptive Father is he who takes the children of some other person, and acknowledges them as his own.

Putative Father is he who is only the reputed or supposed father.

Father is also used in theology to signify the first person in the Trinity.

Father, in *Ecclesiastical History,* is applied to ancient authors who have preserved in their writings the traditions of the church. Thus, St Chrysostom, St Basil, and others, are called Greek Fathers; St Augustin and St Ambrose, Latin Fathers. No author who wrote later than the twelfth century is dignified with the title of Father.

Father is also a title of honour given to prelates and dignitaries of the church, to the superiors of convents, to congregations of ecclesiastics, and to persons venerable for their age or quality. Thus we say, the right reverend father in God, the father general of the Benedictines, the fathers of the council of Nice, the father of his country, and so in many other cases.

FATHOM, a lineal measure containing six feet, and used chiefly at sea for measuring the length of cables and cordage.

FATSISIO, a barren and almost inaccessible island, about eighty miles from the south coast of the isle of Niphon. Thither criminals are banished, and employed in making gold brocade. Long. 140. 10. E. Lat. 33. 40. N.

FATUARII, in *Antiquity,* were persons who, appearing inspired, foretold things to come. The word is formed from *Fatua,* wife of the god Faunus, who was supposed to inspire women with the knowledge of futurity, as Faunus himself did men. Fatua had her name from *fari,* used in the same sense as *vaticinari,* to prophesy.

FAUNA, a deity amongst the Romans, who was daughter of Picus, and originally called *Marica.* Her marriage with Faunus procured her the name of *Fauna,* and her knowledge of futurity that of *Fatua* and *Fatidica.* It is said that she never saw a man after her marriage with Faunus, and that her uncommon chastity occasioned her being ranked among the gods after death. According to some, she is the same as *Bona Mater.*

FAUNALIA, in *Antiquity,* Roman feasts celebrated in honour of the god Faunus, who was the same amongst the Romans as *Pan* amongst the Greeks.

The Faunalia were held on the day of the nones of December, or on the fifth day of that month. The principal sacrifice was a roebuck, or rather, according to Horace, a kid, attended with libations of wine and the burning of incense. It was properly a country festival, being performed in the fields and villages with peculiar joy and devotion. Struvius in his Roman kalendar marks the feast of Faunus on the day of the ides of February; and the Faunalia he places on the fifth of the ides of December, or the 9th of that month. He also shows, that there really were two Faunalia; the one in February, mentioned by Ovid (*Fast.* lib. iv. ver. 246), and the other on the 9th of December, mentioned by Horace in the eighteenth ode of his third book.

FAUNS (*Fauni*), among the ancients, were a species of demi-gods inhabiting the forests, called also Sylvans (*Sylvani*), and differing little from the Satyrs. They delighted more particularly in vineyards, and generally appear as attendants of Bacchus, in the representation of Bacchanalian feasts and processions. The Fauns were represented as half men, half goats, having the horns, ears, feet, and tail of a goat, a very flat nose, and the rest of the figure human. Though the Fauns were considered as demi-gods, yet they were supposed to die after a long life. Arnobius shows that their father or chief, Faunus himself, lived only a hundred and twenty years.

FAUSSIGNY, a province of the duchy of Savoy, in the kingdom of Sardinia, with the title of a barony. It extends over 748 square miles, and contains three cities and seventy-two towns and villages, with 54,520 inhabitants. It is one of those provinces the neutrality of which was fixed by the congress of Vienna.

FAUSTUS. See Fust.

FAVERSHAM. See Feversham.

FAVIGNANA, an island on the west coast of Sicily, in the Mediterranean, named collectively the Formiche. It is situated to the south of Levanso, is a very fertile spot, and contains 2500 inhabitants, who grow corn, oil, wine, and cotton.

FAVISSÆ, in *Antiquity,* were, according to Festus and Aulus Gellius, cisterns for containing water. But the *favissæ* in the capitol at Rome were subterranean cellars, where old statues, broken vessels, and other things used in the temple, were usually laid up. They were much the same with the *archives* and *treasury* of modern churches.

FAVONIUS, amongst the Romans, the wind which blew directly from the west.

FAVORINUS, an ancient orator and philosopher of Gaul, who flourished under the emperor Hadrian, and taught with high reputation both at Athens and Rome. Many works are attributed to him, amongst which may be mentioned a Greek miscellaneous history, often quoted by Diogenes Laertius.

FAWKES, Francis, a poet of some note, who received his school education at Leeds, whence he was removed to Jesus College, Cambridge, where he took the degrees in arts. Having early entered into holy orders, he settled first at Bramham in Yorkshire, near the elegant seat of that name, which he celebrated in verse in 1745, in a quarto pamphlet published anonymously. His first poetical publications were, Gawin Douglas's Description of May and Winter modernized. Having afterwards removed to the curacy of Croydon in Surrey, he recommended himself to the notice of Archbishop Herring, then residing there on account of his health, to whom, besides other pieces, he addressed an ode on his recovery in 1754, which is printed in Mr Dodsley's collection. In 1755 his grace collated him to the vicarage of Orpington, with St Mary Gray in Kent; and Mr Fawkes lamented his patron's death in 1757 in an elegy styled *Aurelius,* first printed, with his grace's seven sermons, in 1763. In April 1774, by the favour of Dr

Plumtree, he exchanged his vicarage for the rectory of Hayes. He was also one of the chaplains to the princess dowager of Wales. He published a volume of poems by subscription in 8vo, 1761; the Poetical Kalendar, 1763, and Poetical Magazine, 1764, in conjunction with Mr Woty; Partridge Shooting, an eclogue, to the honourable Charles Yorke, 1767, 4to; and a Family Bible with notes, in 4to, a compilation. But his great strength lay in translation, in which, since Pope, few have surpassed him. His fragments of Menander; his works of Anacreon, Sappho, Bion, Moschus, and Musæus, 12mo, 1760; his Idyllia of Theocritus, by subscription, 8vo, 1767; and his Argonautics of Apollonius Rhodius, by subscription, a posthumous publication, completed by the Reverend Mr Meen of Emanuel College, Cambridge, 8vo, 1780, may be referred to in proof of this observation. He died on the 26th August 1777.

FAWN, among sportsmen, a buck or doe of the first year, or the young one of the buck's breed in its first year.

FAYOUM, a province of Egypt. See the article EGYPT.

FE, SANTA, a city of Spain, on the river Xenil, in the province of Granada, which was almost entirely overthrown by an earthquake in 1807. Near to it is Sota de Roma, the estate conferred on the Duke of Wellington by the government of Spain.

FE, FO, or FOHI, the name of the chief god of the Chinese, whom they adore as the sovereign of heaven. They represent him as shining all in light, with his hands hid under his robes, to show that his power does all things invisibly. He has at his right hand the famous Confucius, and at his left Lanza or Lanca, chief of the second sect of their religion.

FEALTY, in *Law*, an oath taken on the admittance of any tenant, to be true to the lord of whom he holds his land. By this oath the tenant holds in the freest manner, on account that all who have fee hold *per fidem et fiduciam*, that is, by fealty at the least.

This fealty, at the first creation of it, bound the tenant to fidelity, the breach of which was the loss of his fee. It has been divided into general and special; general, that which is to be performed by every subject to his prince; and special, required only of such as, in respect of their fee, are bound by oath to their lords. To all manner of tenures, except tenancy at will, and frank-almoign, fealty is incident, though it chiefly belongs to copyhold estates held in fee and for life.

FEAR is defined an apprehension of impending evil, attended with a desire of avoiding it. Fear in the extreme is called *terror*. Fear, in Scripture, is used in various senses. The *fear of God* is either filial or servile. Filial fear is a holy affection or gracious habit in the soul, by which it is inclined to obey all God's commandments, and to hate and avoid evil. Slavish or servile fear is the consequence of guilt; a judicial impression produced by sad thoughts of the provoked majesty of heaven; an alarm within that disturbs the rest of a sinner. Though this fear be in wicked men, yet it is often preparative to faith and repentance. *Fear* is likewise used for the *object* of fear. God says that he will send his *fear* before his people; that is, a dread wrought by him, in order to terrify and destroy the inhabitants of Canaan.

FEAR was deified by the Pagans. Tullius Hostilius brought the worship of this deity to Rome. The Ephori of Sparta erected a temple to Fear, near their tribunal, in order to strike awe into those who approached it. Fear was likewise worshipped at Corinth.

FEAST, or FESTIVAL, in a religious sense, is the ceremony of feasting and thanksgiving. The word is formed from the Latin *festum*, which some derive *a feriari*, to keep holiday; others, however, derive it from the Greek ἑστιαω, *I feast* or *entertain*, from ἑστια, *hearth*, or *fire*. Feasts and the ceremonies connected with them have formed great part of the religion of almost all nations and sects; of the Greeks, Romans, Hebrews, Christians, and Mahommedans.

The first feasts amongst the Greeks were celebrated in solemn assemblies of the whole nation, on occasion of their games, as the Olympian, the Pythian, the Isthmian, and Nemæan; but in process of time they had many others, the principal of which are enumerated in the course of this work.

The Romans also had abundance of stated feasts in honour of their deities and heroes; as the Saturnalia, Cerealia, Lupercalia, Liberalia, Neptunalia, Consualia, Portumnalia, Vulcanalia, Palilia, Divalia, and others. They had also feasts instituted occasionally, as Carmentalia, Quirinalia, Terminalia, Floralia, Compitalia, Lemuria, Vernalia; besides other moveable and occasional ones, to give thanks to the gods for benefits received; to implore their assistance, or to appease their wrath, as the Paganalia, Feralia, Bacchanalia, Ambarvalia, Amburbalia, Suovetaurilia, and various others, denominated *feriæ;* as Sementinæ, Latinæ, &c. The feasts were divided into days of sacrifice, and days of banqueting and feasting; days of games, and days of rest or *feriæ*. As there was but little history written, or at least published, in those days, one end of these feasts was to preserve the remembrance of past occurrences.

The principal festivals of the Jews were the feast of trumpets, that of the expiation, that of tabernacles, that of the dedication, that of the passover, that of pentecost, and that of purification. The modern Jews have other feasts marked in their kalendar, but these are of modern institution. The Mahommedans, besides their weekly feast or Sabbath, which is observed on Friday, have two solemn feasts, the first of which is called the Feast of Victims, and celebrated on the tenth day of the last month of their year; and the second is called Bairam. The Chinese have two solemn annual feasts, in the memory of Confucius, besides others of less note on various days of the year.

Festivals amongst us are either *immoveable* or *moveable*. *Immoveable feasts* are those constantly celebrated on the same day of the year. The principal of these are Christmas day or the Nativity, the Circumcision, Epiphany, Candlemas or the Purification, Lady Day or the Annunciation, called also the Incarnation and Conception, All Saints, and All Souls; besides the days of the several apostles, which with us are feasts, though not *feriæ*. *Moveable feasts* are those which are not confined to the same day of the year. Of these, the principal is Easter, which gives the law to the rest, all of them following and keeping their proper distances from it; as Palm Sunday, Good Friday, Ash-Wednesday, Sexagesima, Ascension-Day, Pentecost, and Trinity-Sunday. The four feasts which the English laws take special notice of are, the Annunciation of the blessed Virgin Mary, or Lady Day, the 25th of March; the nativity of St John the Baptist, on the 24th of June; the Feast of St Michael the Archangel, on the 29th of September; and that of St Thomas the Apostle, on the 21st of December.

Besides these feasts, which are *general*, and enjoined by the church, there are others *local* and *occasional*, enjoined by the magistrate, or voluntarily observed by the people; as days of thanksgiving for delivery from wars, plagues, and other evils; and also the vigils or wakes in commemoration of the dedication of particular churches.

The prodigious increase of festival days in the Christian church commenced towards the close of the fourth century, and was occasioned by the discovery which was then made of the remains of martyrs and other holy men, for the commemoration of whom they were established. But instead of being set apart for pious exercises, these festivals were abused in indolence, voluptuousness, and criminal practices. Many of them were instituted on a Pâgan model, and perverted to the most scandalous purposes.

Feast is also used to signify a banquet or sumptuous entertainment, without any immediate view to religion.

The use of the word, in this sense, arises from the circumstance that part of the ceremony in many of the ancient festivals, both those of the heathens and of the Christians, was good eating; though Huet chooses to derive the word from *festinare*, which, in an ancient Latin version of Origen's Commentary on Matthew, signifies to feast: *Ut veniens illuc Jesus festinet, cum discipulis suis.*

Social or civil feasts were also expressed by the words *convivium* and *compotatio* or *concœnatio*. Cicero says that, in the Roman language, the word *convivium*, which means people assembled at table, is more significant of refinement than the Greek word *compotatio* or *concœnatio*. The Roman term, says he, expresses the conjunction of body and mind which ought to take place at an entertainment; the Greek merely denotes what relates to the body alone.

As food is necessary to our existence, eating together forms a bond of association among mankind. People at a feast, says one of the ancients, seem to form but one body and one soul. All nations, whether savage or civilized, have regarded the pleasures of the table as the occasion of the most agreeable society. This species of enjoyment, abstracting from its susceptibility of abuse, makes but one family of all whom it brings together. It levels the distinctions introduced by policy or prejudice, and disposes men to regard one another as brethren. It is here that people feel the equality established by nature, forget the evils of life, extinguish their hatred, and cause their enmities to cease. For this reason Aristotle considers as a breach of the social principle the custom of eating apart which obtained amongst the ancient Egyptians, and praises the convivial repasts established by Minos and Lycurgus.

The Persians generally deliberated on business at table, but never determined or put their determinations in execution, except in the morning before having eaten.

When the Germans, says Tacitus, wanted to reconcile enemies, to form alliances, to appoint chiefs, or to treat of war and peace, it was during the repast that they took counsel; a time in which the mind is most open to the impressions of simple truth, or most easily animated to great attempts. These artless people during the conviviality of the feast spoke without disguise, and next day weighed the counsels of the former evening; they deliberated at a time when they were not disposed to deceive, and took their resolution when they were least liable to be deceived.

By a fundamental law of the state, people of rank amongst the Rhodians were obliged to dine daily with those who had the management of affairs, in order to deliberate with them concerning such things as were necessary or useful for the country; and on this account the principal ministers of the kingdom were obliged to keep open table for all who could be of service to the state.

Amongst the Romans, the place where they supped was generally the vestibule, lest a more retired part of the house should encourage licentiousness and disorder. There were several laws which restricted their meals to the vestibules. But when luxury reigned at Rome, the wealthy had superb halls for their entertainments. Lucullus had many, each of which bore the name of some deity; and this was a mark which indicated to the servants the expense of the entertainment. The expense of a supper in Lucullus's hall of Apollo amounted to fifty thousand drachmas. The hall in which Nero feasted imitated the revolutions of the heavens, by the circular motion of its walls and its ceiling; and represented the different seasons of the year, changing at every course, and showering down flowers and perfumes on the guests.

The Romans did not, like us, confine themselves to one table at their feasts; they had generally two; one for the service of animal food, which was afterwards removed; and another for the dessert, at which last they sung, and poured out their libations. The Greeks and eastern nations observed the same custom, and even the Jews in their solemn feasts and at sacrifices.

The Romans, in the time of Nero, had tables made of citron wood brought from Mauritania, which were covered with purple and gold, and raised on feet of carved ivory. It is said that these tables were more precious than gold itself. Dion Cassius affirms that Seneca had five hundred of these, which he made use of one after another; and Tertullian informs us that Cicero had only one. The Romans usually chose the king of the feast, or chairman as we would call him, by a cast of the dice.

We learn from Herodotus that the ancients had neither cups nor bowls, but drank out of little horns tipped with silver or gold.

The Greeks and Romans kept a domestic for the purpose of reading during their meals and feasts. The head of the family sometimes performed the office of reader himself; and we learn that the Emperor Severus often read whilst his family sat or rather reclined at table. The time of reading was generally at supper; and guests were invited to a reading, as they are now a-days to play cards. In their flourishing times the Greeks did not, according to their own expression, profane the sanctity of the table, but rather adorned it with ingenious and elegant conversation, proposing moral topics, of which Plutarch has preserved a collection. Ancient philosophers have remarked, that heroes rarely assembled convivially without bringing affairs of consequence into discussion, or deliberating upon those which regarded either present affairs or future contingencies.

When Rome became corrupted with luxury, singers, dancers, musicians, stage-players, and people who told pleasant tales, were brought into the hall to amuse the guests. Plutarch informs us that Cæsar, after his triumphs, treated the Roman people at twenty-two thousand tables; and by calculation it would seem that there must have been at these tables upwards of two hundred thousand persons.

It was a custom among the Romans, at the end of a feast, to drink out of a large cup as often as there were letters in the names of their mistresses.

Feasting seems to have been the chief delight of the Germans, Gauls, Britons, and all the other Celtic nations; and in this they indulged themselves to the utmost, as often as they had an opportunity. "Amongst these nations," says an author who had carefully studied their manners, "there is no public assembly, either for civil or religious purposes, duly held; no birth-day, marriage, or funeral, properly celebrated; no treaty of peace or alliance rightly cemented, without a great feast." It was by frequent entertainments of this kind that the great men or chieftains gained the affections and rewarded the services of their followers; and those who made the greatest feasts were sure to be most popular, and to have the largest retinue. These feasts, in which plenty was more regarded than elegance, commonly lasted several days, and the guests seldom retired until they had consumed the provisions and exhausted the liquors provided for the occasion. Athenæus describes an entertainment given by Arcamnes, a wealthy prince of Gaul, which continued a whole year without interruption, and at which all the people of Gaul, and even all strangers who passed through that country, were made welcome. At these feasts they sometimes consulted about the most important affairs of state, and formed resolutions relating to peace and war; imagining that men spoke their real sentiments with the greatest freedom, and were apt to form the boldest designs, Feather ‖ Fechingse.

when their spirits were exhilarated with the pleasures of the table. The conversation at these entertainments frequently turned on the great exploits which the guests themselves or their ancestors had performed in war; a circumstance which sometimes occasioned quarrels, and even bloodshed.

As to the drink used at these feasts, particularly in Britain, it seems probable that before the introduction of agriculture into the island, mead, or honey diluted with water, was the only strong liquor known to its inhabitants, as it was to many other ancient nations. And this continued to be a favourite beverage amongst the ancient Britons and their posterity long after they had become acquainted with other liquors. The mead-maker was the eleventh person in dignity in the courts of the ancient princes of Wales, and took place next to the physician. An ancient law of that principality shows how much this liquor was esteemed by the British princes. "There are three things in the court which must be communicated to the king before they are made known to any other person: first, every sentence of the judge; second, every new song; and, third, every cask of mead." This was perhaps the liquor which is called by Ossian the joy and strength of shells, with which his heroes were so much delighted. After the introduction of agriculture, ale or beer became the most general drink of all the British nations who practised that art, as it had long been of all the Celtic nations on the Continent. If the Phœnicians or Greeks imported any wine into Britain, it was only in small quantities; and that generous liquor was but little known in this island until after it had been conquered by the Romans.

In the reign of Charles V. of France, the custom of placing the lights upon the table had not yet been introduced. A number of domestics held the lights in their hands during the whole time of the repast.

FEATHER, in *Physiology*, a general name for the covering of birds; it being common to the animals of this class to have their whole body, or at least the greater part of it, covered with feathers or plumage. Feathers form a considerable article in commerce, particularly those of the ostrich, heron, swan, peacock, and goose, for plumes, ornaments of the head, filling of beds, writing-pens, and the like.

Geese are plucked five times a year in some parts of Great Britain; and in cold seasons many of them die by this barbarous custom. Those feathers which are brought from Somersetshire are esteemed the best, and those from Ireland the worst.

Eider down is imported from Denmark; the ducks which supply it being inhabitants of Hudson's Bay, Greenland, Iceland, and Norway. Our own islands west of Scotland breed numbers of these birds, which form a profitable branch of trade to the poorer class of the inhabitants. Hudson's Bay also furnishes very fine feathers, supposed to be of the goose kind. The down of the swan is brought from Dantzic.

FEBRIFUGE, an appellation given to such medicines as serve to mitigate or remove a fever.

FEBRUARY, in *Chronology*, the second month of Numa's year. This month is not found in the calendar of Romulus, but was added to the year by Numa. It had its name from *Februa*, *Februaca*, or *Februalis*, all names of Juno, who presided over the purifications of women; in this month also the Lupercalia were held in honour of Juno, and women were purified by the priests of Pan Lyceus at that festival. February, in a common year, consists only of twenty-eight days; but in bissextile year it has twenty-nine, on account of the intercalary day added that year.

FECHINGSE, a small and neatly-built city of China, in the province of Pe-tche-li, near Pekin. It has a good appearance, though the houses are low, from the walls and pavilions being kept in good repair. Near the town is a fine bridge crossing the river; it is built of stone, and is 216 paces in length.

F mp ‖ e.

FECAMP, a sea-port city of the department of the Lower Seine, in France, situated at the mouth of the river of the same name. It has a good tide harbour. It contains 1000 houses and 7939 inhabitants, many of whom are employed in the herring and mackerel fisheries, some in ship-building, and others in the manufacture of sail-cloth, flannels, counterpanes, and tent-cloth. Long. 0. 16. 40. E. Lat. 49. 46. N.

FECIALES, or Fœciales, an order of priests or officers amongst the ancient Romans, consisting of twenty persons, appointed to proclaim war, to negotiate peace, and to perform various other duties.

Festus derives the word from *ferio*, I strike, as *ferire fœdus* signifies to conclude a treaty; and accordingly, instead of *feciales* he would have it written *feriales*. Others derive it from *fœdus*, which was anciently written *fedus*, probably from *fides*, faith; and others again from *facio*, *feci*, I make, because they made war and peace. Vossius chooses to derive it from *fatu*, the latter supine of the verb *fari*, to speak, in which sense the *feciales* should be the same with *oratores;* and this opinion is also confirmed by the authority of Varro, who says that they were called indifferently *feciales* and *oratores*.

The *feciales* were a sort of heralds, who, when the Romans had any dispute with their neighbours, were sent first to demand the thing intended to be usurped, or to require satisfaction for the injury alleged to be done. If an answer satisfactory to the people and the senate was not returned by them, they were dispatched again to declare war; and the same thing took place in treating for peace, the *feciales* being the only persons appointed to negotiate between the senate and the enemy.

Plutarch, in the life of Numa, and Dionysius of Halicarnassus, observe that the *feciales* were first instituted by that prince. The latter adds that they were originally chosen out of the best families in Rome; that their office, which was reputed a sort of *sacerdotium*, or priesthood, only ended with their life; that their persons were sacred and inviolable, like those of other priests; that they were even charged to see that the republic did not declare war unjustly; that they were authorized to receive the complaints and remonstrances of nations who pretended to have been in any way injured by the Romans; that if these complaints were found just, they were bound to seize the criminals, and to deliver them up to those whom they had offended; that they were invested with the rights and privileges of ambassadors; that they not only concluded treaties of peace and alliance, but took care that these were executed, and even abolished them, if they were found not to be equitable. Livy (lib. i. cap. 24) ascribes the institution of *feciales* to Ancus Martius, in the year of Rome 114. But Varro assures us, that in his time most of the functions of the *feciales* were set aside; though Plutarch observes that they had still some authority in his time.

The *feciales* were crowned with *verbena* or vervain when they proceeded to declare war. The head was covered with a veil, over which the crown was applied. In this equipage they proceeded to the frontiers of the country which had been declared hostile, and threw a bloody dart or javelin into the ground within the same. In Livy and other ancient authors we have the formula used in such declarations.

FEE, in *Law*, signifies a complete feudal property. See Feudal Law.

Fee also signifies a certain allowance or *honorarium* to barristers, physicians, and certain other professional persons, as a reward for their pains and labour.

Fee-Farm, a kind of tenure without homage, fealty, or other service, except that mentioned in the feoffment, which is usually the full rent, or at least a fourth part of it.

FEEJEE Islands, a group of islands in the South Pacific Ocean, the exact number of which has not been ascertained. They are situated from about 15. 33. to 19. 15. of south latitude, and extend to about 175. east longitude. They are equally fertile with the generality of the islands in the South Pacific Ocean, and abound in the same sort of produce. Sandal wood is plentiful, and a considerable trade is carried on with the Europeans in this article. The inhabitants are a ferocious race, being all cannibals. These islands were originally discovered by Tasman in the year 1643. They were seen by Captain Bligh in the years 1789 and 1792; and many European vessels have since visited them.

FEET-Bearer, the name of an officer in the courts of the ancient Anglo-Saxon and Welsh princes. He was a young gentleman, whose duty it was to sit on the floor, with his back towards the fire, and hold the king's feet in his bosom all the time he sat at table, in order to keep them warm and comfortable; a piece of state and luxury unknown, and, we may add, unnecessary, in modern times.

FEHRABAD, or **Fahrabad**, a town of Persia, in the province of Mazanderan, situated on the southern shore of the Caspian Sea, at the mouth of a river. Its population, formerly computed at 16,000, consisted principally of Armenians and Georgians, who are represented as having been lively, active, and industrious. The neighbouring country is fertile, producing sugar, cotton, and silk; and the inhabitants carry on a trade in rice, salt-fish, and pottery. It is 126 miles west of Asterabad, and 270 north of Ispahan. Long. 53. 12. E. Lat. 35. 56. N.

FELANICHE, a Spanish town on the island and in the province of Majorca, with some distilleries of brandy and wine, and with a population of 6800 souls. Long. 0. 14. W. Lat. 39. 32. N.

FELAPTON, in *Logic*, one of the six first modes of the third figure of syllogisms; the first proposition being an universal negative, the second an universal affirmative, and the third a particular negative.

FELEGYAZA, a city of Hungary, in the circle of the Hither Danube, where the archives of the circle are preserved, and all the legal processes are carried on. It is also the head quarters of the army. It contains 1028 houses and 9405 inhabitants. Long. 19. 45. E. Lat. 46. 43. N.

FELIBIEN, Andre', was born at Chartres in 1619, and went as secretary under the Marquis de Fontenay-Mareuil, who was French ambassador at the court of Rome in 1647. On his return M. Colbert procured him the place of historiographer to the king, and also that of superintendent of buildings, and of the arts and manufactures, in France. He became afterwards deputy comptroller-general of the bridges and dykes in that kingdom; and died in 1695. Felibien wrote several pieces relating to the fine arts, the principal of which is his Dialogues on the Lives and Works of the most eminent Painters.

FELICITAS, Felicity, or *Happiness*, was deified by the ancient Pagans. Lucullus built a temple to this goddess, and Lepidus erected another. The Greeks paid divine worship to Macaria, daughter of Hercules, who was the same with the Felicitas of the Romans. This deity is pictured upon medals, generally with a cornucopia in one hand, and a caduceus in the other.

FELICUDI, one of the Lipari Islands, in the Mediterranean Sea, belonging to the kingdom of Naples. It is inhabited by about 1200 persons, who grow wheat and produce wine, some of which is shipped at the small haven.

FELO de Se, in *Law*, a person who deliberately lays violent hands on himself, and is the occasion of his untimely death, whether by hanging, drowning, stabbing, shooting, or in any other way.

FELON, in *Law*, a person guilty of felony.

FELONY, in the general acceptation of the law, comprehends every species of crime which occasions at common law the forfeiture of lands or goods. This most frequently happens in those crimes for which a capital punishment either is or used to be inflicted; for those felonies which are called *clergyable*, or to which the benefit of clergy extends, were anciently punished with death in all lay or unlearned offenders; though now, by the statute law, that punishment is for the first offence universally remitted. Treason itself, says Sir Edward Coke, was anciently included under the name of *felony*; and in confirmation of this we may observe, that the statute of treasons (25 Edw. III. c. 2), speaking of some dubious crimes, directs a reference to parliament, that it may be there adjudged "whether they be treason or *other* felony." All treasons, therefore, strictly speaking, are felonies; though all felonies are not treason. And to this also we may add, that all offences now capital are in some degree or other felonies; but this is likewise the case with some other offences which are not punished with death, as suicide, where the party is already dead, homicide by chance-medley or in self-defence, and petit-larceny or pilfering; all which are, strictly speaking, felonies, as they subject those who commit them to forfeitures. Upon the whole, therefore, the only adequate definition of felony seems to be that which was before laid down, namely, an offence which occasions a total forfeiture of either lands or goods, or both, at the common law, and to which capital or other punishment may be superadded, according to the degree of guilt.

The word *felony*, or *felonia*, is undoubtedly of feudal original, being frequently to be met with in the books of feuds, and in other works; but the derivation of it has much puzzled the juridical lexicographers Pratæus, Calvinus, and others. Some derive it from the Greek φηλος, *an impostor* or *deceiver*; others from the Latin *fallo, fefelli*, to countenance which they would have it called *fellonia*. Sir Edward Coke, as his manner is, has given us a still stranger etymology; that it is *crimen animo felleo perpetratum*, a crime perpetrated with a bitter or gallish inclination. But all agree in the description that it is such a crime as works a forfeiture of the offender's lands or goods. And this gives great probability to Sir Henry Spelman's derivation from the Teutonic or German, in which language, indeed, as the word is clearly of feudal origin, we ought rather to look for its signification, than amongst the Greeks and Romans. *Felon*, then, according to him, is derived from two northern words, namely, fee, signifying the fief, feud, or beneficiary estate; and lon, which means price or value. Felony is therefore the same as *pretium feudi*, the consideration for which a man gives up his fief; as we say in common speech, such an act is as much as your life or estate is worth. In this sense it clearly signifies the feudal forfeiture or act by which an estate is forfeited, or escheats to the lord.

To confirm this we may observe, that in the sense of forfeiture to the lord, the feudal writers constantly use it. For all those acts, whether of a criminal nature or not, which at this day are generally forfeitures of copyhold estates, are styled *feloniæ* in the feodal law: *scilicet, per quas feudum amittitur*. Thus, *si domino deservire noluerit; si per annum et diem cessaverit in petenda investitura; si dominum ejuravit*, id est, *negavit se a domino feudum habere; si a domino in jus eum vacante, ter citatus non comparuerit*; all which, with many others, are still causes of forfeiture in our copyhold estates, and were denominated *felonies* by the feudal constitutions. So likewise injuries of a more substantial or criminal nature were denominated *felonies*, that is, forfeitures; as assaulting or beating the lord; vitiating his wife or daughter, *si dominum cucurbitaverit*, id est, *cum uxore ejus concubuerit*; all these are esteemed felonies, and the latter is expressly so denominated, *si fecerit feloniam, dominum forte cucurbitando.* And as these contempts or smaller offences were felonies or acts of forfeiture, of course greater crimes, as murder and robbery, fell under the same denomination. On the other hand, the lord might be guilty of felony, or forfeit his seignory to the vassal, by the same act as that by which the vassal would have forfeited his feud to the lord. *Si dominus commisit feloniam, per quam vasallus amitteret feudum si eum commiserit in dominum, feudi proprietatem etiam dominus perdere debet.* One instance given of this sort of felony in the lord is beating the servant of his vassal, so that his service is lost; which seems merely in the nature of a civil injury, in as far as it respects the vassal. And all these felonies were to be determined *per laudamentum sive judicium parium suorum*, in the lord's court; as with us forfeitures of copyhold lands are presentable by the homage in the court-baron.

Felony, and the act of forfeiture to the lord, being thus synonymous terms in the feudal law, we may easily trace the reason why, upon the introduction of that law into England, the crimes which induced such forfeiture or escheat of lands (and, by a small deflection from the original sense, such as induced the forfeiture of goods also) were denominated *felonies*. Thus it was that suicide, robbery, and rape, were felonies; that is, the consequence of such crimes was forfeiture: but by long use we began to signify by the term of *felony* the crime actually committed, and not the penal consequence thereof. And upon this system only can we explain the reason why treason in ancient times was held to be a species of felony; we mean, because it induced a forfeiture.

Hence it follows, that equal punishment does not by any means enter into the true idea and definition of *felony*. Felony may be without inflicting capital punishment, as in the cases instanced of self-murder, excusable homicide, and petit-larceny; and it is possible that capital punishments may be inflicted, and yet the offence be no felony, as in the case of heresy by the common law, which, though capital, never worked any forfeiture of lands or goods, an inseparable incident to felony. And of the same nature was the punishment of standing mute, without pleading to an indictment; which at the common law was capital, but without any forfeiture, so that such standing mute was no felony. In short, the true criterion of felony is forfeiture; for, as Sir Edward Coke observes, in all felonies which are punishable with death, the offender loses his lands in fee-simple, and also his goods and chattels; but in such as are not punishable he loses his goods and chattels only.

The idea of felony is indeed so generally connected with that of capital punishment, that we find it hard to separate them; and to this usage the interpretations of the law now conform. If a statute, therefore, makes any new offence felony, the law implies that it shall be punished with death, that is, by hanging as well as forfeiture, unless the offender pray the benefit of clergy; which all felons are entitled once to have, unless the same is expressly taken away by statute.

FELT, in *Commerce*, a sort of stuff deriving all its consistence merely from being fulled, or wrought with lees and size, without either spinning or weaving. Felt is made either of wool alone, or of wool and hair.

FELTING, the method of working up hair or wool into a species of cloth, independently of either spinning or weaving. Felting in Britain is not much practised, excepting in the manufacturing of hats. See HAT-MAKING.

FELUCCA, in nautical affairs, a little vessel rowed with six oars, and frequent in the Mediterranean. It has this peculiarity, that its helm may be applied either in the head or stern, as occasion requires.

FELUDJE, FELUGIA, a village of Asiatic Turkey, situated on the eastern shore of the Euphrates, north of Hillah, in a fertile soil, productive in dates, grapes, grain, and cotton. Here a palace was erected by Soliman the Great, pasha of Bagdad. It was anciently a place of celebrity, and taken by the Romans under the Emperor Julian.

FELUDSJE, FELUJA, a small island in the north-west part of the Gulf of Persia, near the Arabian shore. It is ten miles east of Koueit. Long. 48. E. Lat. 29. 45. N.

FEMALE (FŒMINA), a term peculiar to animals, signifying that sex which conceives and generates its young.

FEMERN, an island in the Baltic Sea, a part of the kingdom of Denmark, the centre of which is in latitude 54. 29. north, and longitude 10. 24. east. The extent of it is fifty-two square miles, or 33,280 acres. It contains a city and market-town, and forty villages, with 7626 inhabitants. The soil is productive, and the sea around it abounds with fish, the taking of which affords occupation to many of the inhabitants. The capital is Burg.

FEMME COVERT, in *Law*, signifies a married woman.

FEMME Sole, an unmarried woman, whose debts, contracted before marriage, become those of her husband after it.

FEMININE, in *Grammar*, one of the genders of nouns, namely, the second.

The feminine gender is that which denotes that the noun or name belongs to a female. In the Latin the feminine gender is formed from the masculine by altering its termination, particularly by changing *us* into *a*. Thus, of the masculine *bonus equus*, a good horse, is formed the feminine *bona equa*, a good mare; and so, of *parvus homo*, a little man, is formed *parva fœmina*, a little woman.

In French, the feminine gender is expressed, not by a different termination, but by a different article. Thus, *le* is joined to a male, and *la* to a female.

In English, we are generally more strict, and express the difference of sex, not by different terminations nor by different particles, but by different words; as boar and sow, boy and girl, brother and sister; though sometimes the feminine is formed by varying the termination of the masculine into *ess*, as in abbot, abbess, and the like.

FEN, a place overflowed with water, or abounding with bogs. Fens are either made up of a congeries of bogs, or consist of a multitude of pools or lakes, with dry spots of land intermixed, like as many little islands.

FENCE, in *Gardening* and *Husbandry*, a hedge, wall, ditch, bank, or other inclosure, made round gardens, fields, woods, and the like.

FENCE-Month, the month in which deer begin to fawn, and during which it is unlawful to hunt in the forest. It commences fifteen days before midsummer, and ends fifteen days after it. This month, by ancient foresters, is called *defence-month*.

FENCING, is the proper use of the small-sword or foil. The small-sword is a light court-dress sword, made to taper gradually from the hilt to the point, and of a size regulated by the judgment of the wearer, if he understand the use of the weapon. The foil, with which the art of fencing is practised, is a small quadrangular blade, about the length of a small sword, and mounted in nearly the same manner; but, for the convenience of the exercise, it is made lighter, blunted, and covered with leather at the point, to prevent accidents in practice.

The first weapon in use amongst mankind, whether for offensive or defensive purposes, appears to have been the sword, and combat with this weapon is perhaps nearly as old as the world. The most ancient book extant makes frequent mention of the sword, and the same thing may be said of Homer, who is full of continual allusions to this weapon. The earliest swords were probably made of wood, like those used by the natives of Mexico when first visited by the Spaniards; but after the discovery of metals, copper swords were introduced, of which kind many have at different times been found in Ireland. As soon, however, as the art of tempering steel had been discovered, that metal superseded all other substances in the fabrication of arms; nor is it probable that any change in this respect will take place, or that any further improvement is attainable. The form of the sword, however, has varied at different times and in different countries. Those used by the Roman legions were short and strong, with a blade seldom exceeding nineteen inches in length, but two-edged, and calculated both for the cut and the thrust. The British swords, called *spathæ*, were large, long, and heavy; and the Saxon and the Norman partook of the same character. The ancient practice of the weapon was probably carried to its greatest perfection amongst the Romans, whose partiality for gladiatorial exhibitions formed a remarkable feature of their character. The various and complicated methods of combat in which this celebrated people took delight are either alluded to or described by most of their writers, particularly by Livy, Juvenal, Seneca, and Suetonius.

The history of the modern small-sword or rapier is involved in some obscurity. The latter term, though now considered as synonymous with the former, properly denotes a long, ordinary, old-fashioned, cutting sword. But modern usage has identified the expressions, and by a rapier is now always meant a sword for the thrust, in contradistinction to one constructed for cutting. The small-sword or rapier is undoubtedly very ancient, although there is reason to believe that it was not brought into general use until armour began to wear out of fashion. Since that time the art of fencing has always been considered as a gentlemanly accomplishment, and in many parts of the Continent it is cultivated with the greatest zeal and assiduity. Shakspeare, indeed, makes Hamlet, who lived at the court of Florwendillus, a fencer; but as our great dramatist has not been very careful in avoiding anachronisms, it may reasonably be doubted whether the small-sword has any claim to such antiquity. Some have maintained that the weapon was not used in England before the reign of Elizabeth; and Darcie (*Annals of Elizabeth*) informs us that one Rowland York, who appears to have betrayed Deventer to the Spaniards in the year 1587, was the first who brought into England "that wicked, pernicious fashion to fight in the fields in duels with a rapier called a tucke only for the thrust." Stowe also mentions that long tucks and long rapiers began about the twelfth or thirteenth year of Elizabeth, and that "he was held the greatest gallant that had the deepest ruffe and largest rapier. The offence," he adds, "to the eye of the one, and the hurt unto the life of the subject that came by the other, caused her majesty to make proclamation against them both, and to place selected grave citizens at every gate to cut the ruffes and breake the rapier's points of all passengers that exceeded a yard in length of their rapiers, and a nayle of a yard in depth of their ruffes."[1]

But at what time soever the small-sword came into use in this country, it is not surprising that, when once introduced, it should have been cultivated as the fairest and most equitable instrument of duelling. Before this period meetings for the purpose of single combat were utterly revolting to human nature. No regard was paid to equality of arms or numbers; advantages, however unfair, were seized whenever an opportunity offered; and the ferocious passions, instead of being curbed, had fuller scope given for their gratification. "The duellist of former times," says Sir Walter Scott, in a note to *The Lady of the Lake*, "did not always stand upon those punctilios respecting equality of arms, which are now judged essential to fair combat. It is true that in formal combats in the lists, parties were, by the judges of the field, put as nearly as possible in the same circumstances. But in private duels it was often otherwise." In the desperate combat which was fought between Quelus, a minion of Henry III. of France, and Antraquet, with two seconds on each side, and from which only two persons escaped alive, Quelus complained that his antagonist had the advantage of a poniard which he used in parrying, whilst his own left hand, which he was obliged to use for the same purpose, had been cruelly mangled. When he charged Antraquet with this odds, "Thou hast done wrong," answered the latter, "to forget thy dagger at home; we are here to fight, not to settle punctilios of arms." In another duel of a similar kind, however, a younger brother of the house of Aubange in Angoulême behaved more generously, and at once threw away his dagger when his antagonist challenged it as an undue advantage. Nevertheless, it would be difficult to conceive any thing more brutal and savage than the mode in which private quarrels were at this time conducted in France. Those who were most jealous on the point of honour, and who thence acquired the title of *raffinés*, did not scruple to avail themselves of every advantage of strength, numbers, surprise, and arms, in order to accomplish their revenge.

Brantôme, in his discourse on duels, informs us that the Italian masters of the science of defence made a great mystery of their art and mode of instruction; that they never suffered any person to be present except the scholar who was to be taught, and even examined beds, closets, and other places of probable concealment. The lessons of these teachers often gave the most treacherous advantages to their pupils; for the challenger having by usage a right to choose his weapons, frequently selected some strange and inconvenient kind of arms, the use of which he had practised under his instructor, and thus killed at his ease an antagonist, to whom, perchance, the weapon was presented for the first time on the field of battle. Nor can we doubt that the same, or even still more treacherous advantages, are taught by some Italian masters of the present day, especially when we learn, from an authentic publication of the life of a late pope, that in Rome upwards of a thousand persons annually fall victims to the stiletto, either by the hands of hired assassins, or in private quarrels. Dr Moore estimates the number of murders perpetrated by the dagger in Naples alone at not less than four hundred annually. Such are the cowardly and ferocious modes in which vengeance usually seeks its gratification amidst an enslaved and degraded people.

The practice of deciding duels with the sword, however, may be considered as now extinct in this country. When the rapier was looked upon as an indispensable part of a gentleman's dress, the facility of immediate rencounter which it offered gave occasion to frequent and dangerous brawls, by which the public tranquillity was disturbed, and the lives of peaceable citizens sometimes sacrificed. But still it may reasonably be doubted, whether the comparatively rare occurrence of duels since the introduction of the pistol, be not fearfully overbalanced by a long list of fatal results, not to mention amputated limbs and distressing mutilations. Be this as it may, however, the discontinuance of sword duels in England has, in a great measure, removed one of the chief objections against fencing; namely, that adroitness in the use of weapons creates a fondness for contention, and a disposition to indulge in violence and insult. Since arms have ceased to be worn, such an objection can no longer be urged against the art of defence; and it may perhaps be questioned whether it had much weight, even when arms formed part of the equipment of every one who called himself a gentleman. All parties were thus placed upon nearly an equal footing; and if turbulent characters went about armed, there was nothing to prevent the peaceably disposed from being as well provided as the brawlers, and also on a par with them in respect of skill in the use of weapons. If the thief makes use of a crowbar, the honest housekeeper has the protection of an iron bolt. The primary intention of fencing is the security of one's own person; and where the weapons and the art of using them skilfully were equally accessible to all, the evil disposed had no advantage, and therefore small temptation to indulge their turbulent propensities.

---

[1] In *The Two Angry Women of Abingdon*, a comedy printed in 1599, we find the following pathetic complaint: "Sword and buckler fights begin to grow out of use. I am sorry for it; I shall never see good manhood again. If it be once gone, this poking fight of rapier and dagger will come up; then a tall man, and a good sword-and-buckler man, will be spitted like a cat or a rabbit."

The practice of the foil in England, however, is now confined to the most laudable purposes, namely, the enjoyment of salutary recreation, and the acquisition of a graceful and unconstrained deportment. The beneficial effects of moderate fencing to persons of weak constitutions, or of studious and sedentary habits, have been attested by medical practitioners of the first eminence. On this subject the suffrages of the most distinguished members of the British schools of medicine and of surgery, which Mr Angelo has annexed to his engravings, illustrative of the fencing attitudes, seem completely decisive.[1] To the public speaker, also, the practice of the fencing-room has been found to impart an ease and freedom of gesture attainable perhaps by no other exercise, not excepting even the discipline of the ballet-master. A modern writer on the subject of delivery or elocution, gives it as his opinion that the use of the foil and the broadsword diffuses ease, elegance, and grace all over the body, and imparts to the look and gesture an appearance of intellectual vigour. It does more; it teaches invaluable lessons of patience and self-command, and contributes to discipline the temper, whilst it serves to develope the corporeal powers, and to strengthen them by unconstrained and salutary exercise. We may add here, that several works of merit have appeared on this subject; but the most valuable and complete one yet published is Roland's *Treatise on the Theory and Practice of the Art of Fencing*, Edinburgh, 1823; nearly all the others we have met with being deficient either in explanation or in practical utility.

Having already described the weapons used in fencing, we shall now proceed to give such definitions as appear to be requisite for conveying a general idea of the subject, referring the reader for the necessary details to the excellent work of Mr Roland, which will be found equally clear in its explanations, and comprehensive in its views of every branch of the art.

After the first positions have been acquired, the different modes of attack come to be considered. *Attacks* are made in three ways: first, by a quick thrust proceeding merely from the wrist, the arm at the same time being elevated and advanced, with the point directed towards the adversary's breast; secondly, by what is technically called an extension; and, lastly, by longeing and recovering. The *parades*, in which consists the defensive part of the art, naturally follow the attack. A parade is a defence of the body, made by an opposition of one's blade to that of an adversary, in such a situation as, upon his attack, to prevent the point of his sword hitting. The parades are eight in number, viz. six simple, and two round or counter parades, and they are called *quarte, tierce, circle, octave, prime, quinte*, and round or counter in quarte and tierce. When and how these parades are made in fencing may be learned by consulting Mr Roland's work (p. 32 et seqq.).

The next division of the subject includes *straight thrusts, simple disengagements*, and *bindings of the blade*. A *straight thrust* is used as an attack, when an antagonist, from his position on guard, leaves sufficient opening to enable him to be touched upon that side of the body on which blades are joined. When such an opportunity offers, the wrist must be suddenly raised, so as to bring the *forte* of one's sword to the *foible* of the adversary's; after which *longe* immediately on the same line to his breast, observing, however, to preserve a correct opposition. In fencing, *opposition* signifies the art of covering the body at the time of delivering a thrust, on that side where the foils happen to cross, in order to prevent an antagonist exchanging hits. The *disengagement* is made either as an attack, or as a return after defending one's-self from a thrust, and is executed both under and over the wrist or foils. A disengagement over the arm may be parried with tierce or prime, and, if made low, by the parade of circle; from the position of octave, by quarte, or, if the thrust be delivered low, by circle; from the position of quinte, by prime as the readiest defence, but quarte and tierce are also correct parades against this thrust. There are three different ways of *binding the blade*. Of these, *flanconnade* is the principal, as it is sometimes a safe attack when any other mode would be attended with considerable danger; it is also made as a *riposte*. The attack of flanconnade is commenced when the blades are joined in quarte, and it is parried either by octave or quinte, or by the parade of quarte. The return over the arm, after the parade of circle, is parried by prime or tierce, or by changing quickly to the counter in quarte. The return over the arm, after the parade of prime, is parried by prime or tierce, or, if made at a considerable distance, by the counter in quarte.

In fencing there are a great variety of *feints*, which it is not easy to describe intelligibly without figures. A *feint* is an intentional movement made to deceive an adversary. All thrusts, therefore, may, strictly speaking, come under the definition of feints, as the fencer's object, in all his attacks, is to deceive his antagonist. For the sake of convenience, however, straight thrusts and simple disengagements have been arranged under a separate head. In executing the feint called *one, two*, inside of the arm, supposing the adversary's body to be covered in quarte, the parade of tierce is deceived; commencing from the outside, that of quarte is deceived; from the position of the circle the octave, and from that of the octave the circle is deceived.

---

[1] "Perhaps there is no exercise whatever," says Mr Roland, "more calculated for these purposes (developing and cultivating bodily strength and activity) than fencing. Riding, walking, sparring, wrestling, running, and pitching the bar, are all of them certainly highly beneficial; but, beyond all question, there is no single exercise which combines so many advantages as fencing. By it the muscles of every part of the body are brought into play; it expands the chest, and occasions an equal distribution of the blood, and other circulating fluids, through the whole system. More than one case has fallen under the author's own observation, in which affections of the lungs, and a tendency to consumption, have been entirely removed by occasional practice with the foil; and he can state, upon very high medical authority, that since the institution of a *Salle d'Armes* at Geneva, scrofula, which was long lamentably prevalent there, has been gradually disappearing." (*Theory and Practice of Fencing*, p. 163.)

This feint, if made inside the arm, is parried by the parade of quarte, or by the counter in tierce, made upon an opponent's second disengagement; upon the outside of the arm, by tierce, prime, or the counter in quarte; and from the position of the octave, by octave or quinte. The feint *one, two*, is likewise made as a return after the parade of quarte or tierce, or sometimes after that of circle or octave. The *cut and disengage* is a species of *one, two*, in making which from the position of quarte, an adversary's parade of tierce is deceived, and from the position of tierce his parade of quarte. *Cut and disengage*, if made inside of the arm, is parried by quarte, or the counter in tierce; if outside, by tierce or counter in quarte. *Feint seconde* is another feint very nearly resembling *one, two*, and is generally made as a return after the parades of tierce, prime, or quinte. In this feint the octave or quinte is deceived; and it is parried by tierce, prime, or quarte, the two former being the readiest where quinte is the parade deceived, but if the feint has been answered with octave, the thrust must then be parried with quarte. The feint *one, two, three*, is made on either side of the blade, upon precisely the same principles as *one, two;* the only difference between them consisting in making one disengagement more in the latter than in the former movement. The *cut and one two* is a species of *one, two, three.* These feints, if made over the arm, are parried with the simple parade of tierce; if on the inside, with simple quarte. The other feints are, *doubling*, which, *mutatis mutandis*, is executed upon precisely the same principles; *one two and deceive the circle*, executed from the inside position of quarte; *one two and deceive the counter*, which may be made from either side of the blade, but is most frequently used commencing from the position of tierce; *feint flanconnade*, which can be commenced only from the engagement of quarte; *feint one two and deceive octave*, which is commenced either from the outside or inside engagement; *feint seconde and deceive quarte*, which is always commenced from the outside engagement, whether made as an attack or a return; *feint seconde and deceive tierce*, which differs from the preceding only in the last disengagement; *one two and deceive quarte from the position of the circle*, when the first disengagement is made over the adversary's wrist towards the body under the arm, and the second over the wrist towards the inside of the body; and *doubling on both sides of the arm*, which is too complicated a feint to be frequently used in actual fencing, because it is difficult to follow the adversary's sword with certainty through many different parades, and there is much danger of *time thrusts* upon feints which consist of so many disengagements.

Time thrusts are so called because the success of these movements depends entirely upon their being executed at the exact moment of time employed by the adversary in planning or in executing his attack; and, when made correctly, they are by far the most scientific movements in fencing. There are two sorts of time thrusts, in the execution of one of which it is necessary that the blades should cross each other, but for the completion of the other it is not absolutely necessary that the blades should even meet. Those time thrusts in the execution of which the blades cross are more scientific, and expose the fencer less to exchanged hits. There are two time thrusts *in opposition;* one the *time over the arm*, and the other the *time in octave.* The former is applicable to all thrusts, however simple or complex the feint may be, provided the longe is made upon the outside; whereas all longes directed to the inside of the body, or under the arm, are exposed to the time in octave; and thus almost every thrust made in fencing affords an opportunity for one or other of these two movements. Those time thrusts in which the opposition is not essential are made upon incorrect movements of the adversary, when he exposes himself by the wideness of his attacks, or by quitting the blade in a dangerous position, or by making too many disengagements in his feints, or by giving a variety of openings which the judgment of the fencer must determine how he is to take advantage of. This thrust is practised almost entirely upon irregular attacks, and requires great caution to be observed. It has been already stated, that time thrusts in opposition, when correctly made upon good attacks, are, perhaps, the finest movements in fencing; but young fencers should nevertheless attempt them very seldom, from the danger of misjudging the attack, and thus exposing themselves to the certainty of being hit. And the time out of opposition is attended with still greater hazard, as its success depends rather upon the wideness and irregularity of an adversary's movements, than on the security of one's own situation afforded by the opposition in the former species of time thrust.

When fencing was comparatively little known, it was thought necessary that there should be some intermediate practice for the pupil between the lesson of the master and his making the assault; for which purpose, it appears, he was taught to longe, at a proper distance, at the wall. This was called by the French *tirer au mur*, and was considered as useful for planting the learner well upon his legs, accustoming him to measure distance correctly, and causing his motions, in making his extension and longe, to follow one another in the proper succession. But as the art became better understood, observation induced masters to place pupils together for their mutual advantage, the one to attack by simple disengagements, the other to parry by quarte and tierce alternately; and this practice, from its origin, was for a considerable time called *tirer au mur*, a denomination which it still retains amongst fencers of the old school. It is now, however, generally known by the denomination of *quarte and tierce*, and, in its improved state, is not merely intended as an exercise for the scholar, but also as a graceful display of the principal motions of fencing; for which reason it should be invariably practised before commencing the assault, and in fencing before company it is never dispensed with. Quarte and tierce appears very simple in its execution, yet it is exceedingly useful to fencers in all stages of their progress, and difficult to acquire with such correctness that all its movements shall take place in their proper succession, and be made with the grace and precision characteristic of a good fencer. For a description of the method of thrusting quarte and tierce, we must refer the reader to the fifth chapter of Mr Roland's work, section first. The *counters* is also a practice of importance to young fencers, and should consequently be attended to by them.

In the language of the fencing-room, making the *assault* and *playing loose* are synonymous, signifying the practice of attack and defence, or, in other words, a just application of the lessons received, which, in fact, ought to be done as correctly as if with sword in hand. In the assault, the mere movements should be almost mechanical; for the mind being wholly employed in discovering and counteracting the designs of the adversary, as well as in concealing its own, the hand should, on the proper opportunity being given, instantly execute that which the mind conceives, without any consideration of the manner in which the particular motion is to be made, as loss of time would most probably prove fatal to its success. The rules to be observed are few and distinct. The first thing which the attention of a young fencer should naturally be directed to is, the most secure manner in which he can come into the position of the guard, when opposed to an adversary ready to take every advantage of his inexperience. Whilst advancing into distance, it is also an object of importance to have one side of the body secured by the position, particularly that side to which the antagonist's blade is opposed; so that, if he commence an attack during this movement, he must quit the blade in order to direct his thrust or feint at any opening afforded him by the position of his opponent; and the opportunities of attack being few, his designs will thus be the more easily discovered. In short, the commanding an opponent's blade almost obliges him to effect some change in the relative situations of the contending parties, before he advances into distance; and as the necessity of such previous movement must be foreseen, any attempt of this kind is favourable for making an attack on him. And, generally, whilst standing in the position of the guard, it is an advantage to have one side of the body covered, and to command the foible of the adversary's blade. Straight thrusts and simple disengagements, executed with quickness and vigour, should frequently be attempted, even though they do not succeed in hitting; and this counsel should be particularly attended to in fencing with a stranger. Quick simple thrusts are almost the only certain way of ascertaining his favourite parades, and consequently of knowing by what feints to attack him with a probability of success. The suddenness and rapidity of the attack will inevitably extort from him the secret of his favourite defence.

Many masters of the old school, and some, too, of the present day, have treated *disarming* as a matter of importance in the art; but, from its inutility, not to mention danger, in the field, it is now considered by the highest authorities on the subject as incompatible with good fencing. Mr Roland, in the work already referred to, shows by what methods this may be accomplished, and at the same time demonstrates the utter uselessness of the trick, for it is no better. The only advantage of disarming indeed is that of annoying the person disarmed; for, sword in hand, it is rendered nugatory by the use of a sword-knot, with which, it may be presumed, every person at all acquainted with the weapon will take especial care to fasten it to his wrist in a serious affair. As the manœuvre of disarming may therefore be defeated by the most ordinary precaution, attempting it can serve no other purpose than to make one play heavily and unpleasantly; whilst, from the strength it requires for the execution of its movements, it takes from the necessary quickness, and affords an adversary favourable moments of attack during the time an attempt is being made to bind his blade. In short, disarming is considered as characteristic of unskilful fencing; since perfection in the trick can only tend to render fencing disagreeable with the foil and ineffectual with the sword. We may add, that *volting*, *demi-volting*, *pirouetting*, parrying with and opposing the left hand, are manœuvres now totally disused in fencing.

As far back as 1692 a very curious book on the subject of fencing was published by Sir William Hope; it is now very scarce. In 1780 a Lieutenant M'Arthur published a work on fencing, which he dedicated to the Duke of Argyll, and which, we believe, is considered as a respectable performance. But since the latter period nothing worth noticing appears to have been written on the subject, with the exception of Angelo's book, illustrated by engravings, and the works of the two Rolands; of these, the most complete and satisfactory is Mr George Roland's *Treatise on the Theory and Practice of Fencing* above referred to. The only standard French works on the subject are, a Treatise by M. Danet, director of the royal academy of privileged fencing-masters; and one by M. Laboissier; both works of great merit, and highly esteemed in France.

FENELON, FRANÇOIS DE SALIGNAC DE LAMOTTE, was descended of an ancient and illustrious family, and born at the castle of Fénélon in Périgord, on the 6th of August 1651. Under the eyes of a virtuous father, he advanced in his literary studies with equal rapidity and success; and being from childhood nurtured in classical antiquity, and in particular familiarised in his solitude with the masterpieces of Grecian genius, his taste was formed on the purest models, whilst his benign genius was simultaneously developed. Called to Paris by his uncle, the Marquis of Fénélon, to complete his philosophical studies, and commence the course of theology requisite for the vocation to which he was destined, he, at the age of fifteen, underwent the same trial as Bossuet, and preached before an auditory, less distinguished, perhaps, than that which assembled in the hôtel de Rambouillet, but still highly respectable, who listened to him with a mixture of surprise and admiration. But this premature reputation rather alarmed than gratified the Marquis of Fénélon, who, in order to withdraw the young apostle from the seductions of the world and of glory, placed him in the seminary of St Sulpice. In this retreat Fénélon imbibed the evangelical spirit, and acquired the friendship of the virtuous Tronson, the superior of the establishment; and here also he received holy orders. About this time his religious fervour inspired him with the design of devoting himself to the missions in Canada. But being thwarted in this scheme by the apprehensions of his family and the weakness of his constitution, he soon turned his regards towards the missions of the Levant, particularly Greece, where the sacred and the profane, St Paul and Socrates, the church of Corinth, the Parthenon, and Parnassus, equally invited his poetical and religious imagination. Fortunately for the Catholic church and for France, however, this project also misgave; and Fénélon, diverted from distant missions, devoted himself to an apostleship, which he thought not less useful, namely, the instruction of the *Nouvelles Catholiques*, or newly-converted women in Paris. The duties and cares of this employment, in which he buried his genius during ten years, prepared him for the composition of his first work, entitled *Traité de l'Education des Filles*, a masterpiece of delicacy and of reason, which has not been equalled by the author of *Emile* and painter of Sophie. This work was intended for the Duchess of Beauvilliers, the pious mother of a numerous family. In the modest obscurity of his ministry, Fénélon had already formed with the Dukes of Beauvilliers and of Chevreuse that virtuous friendship which resisted equally the seductions of favour and the frowns of disgrace, the smiles of the court and the decree of exile. But in the case of Bossuet he met with an attachment which was destined to be much less durable. Admitted into familiarity with this great man, Fénélon studied his genius and his life; and the example of Bossuet, whose polemical religion exercised itself in controversies and conversions, probably suggested to him the *Traité du Ministère des Pasteurs*, a work in which he combats the heretics with a moderation which formed no part of the character of his illustrious model. The subject, the merit of this work, and the all-powerful suffrage of Bossuet in its favour, induced Louis XIV. to confide to Fénélon the charge of a new mission to Poitou. The rigorous uniformity which the French monarch was desirous of establishing in matters of religion, and the resistance which sprung from the oppressive measures adopted for this purpose, often obliged the monarch to cause his missionaries be supported by troops. Fénélon, however, not only rejected peremptorily the co-operation of the dragoons, but even reserved to himself the choice of the ecclesiastical colleagues who should share with him in the ministry of persuasion and gentleness. He converted without persecuting, and made the faith of which he was the apostle an object of love instead of hatred. The importance which was then attached to such missions fixed all eyes upon Fénélon, who had so happily acquitted himself of that entrusted to his care.

A great object was now presented to his ambition and his talents. The dauphin, grandson of Louis XIV., had at length passed the period of childhood, and the king was looking out for a person to whom the education of the young prince might be confided. This was in the year 1689. By the favour of Madame de Maintenon, virtue obtained the preference in this appointment. M. de Beauvilliers was named governor, and he recommended to the king Fénélon as preceptor of the young prince. These virtuous friends, seconded by the attentions of men worthy of imitating them, commenced the task of educating the future king; and history attests that there was never seen a more perfect concurrence of principle and exertion. But Fénélon, by the natural superiority of his genius, formed the soul of this reunion; it was he who, transported by the hope of one day realizing the *beau ideal* of a prince on the throne, and viewing the happiness of France as in a great measure dependent on the education of its future sovereign, destroyed with admirable art all the dangerous germs which nature and the premature sentiment of power had implanted in his youthful breast, and gradually moulded an almost indomitable character to the habit of the most salutary virtues. This system of education, precious vestiges of which remain in some of the writings of Fénélon, appears to have been a masterpiece of that genius which devotes itself to advance the happiness of mankind. When brought into the midst of the court, Fénélon, without intermingling in its intrigues, secured general admiration by the graces of his brilliant and ready wit, and the charm of his noble and eloquent conversation. In his character the apostle and the great lord seemed to be strangely united. Imagination and genius escaped him on all occasions; and the most refined politeness at once embellished and rendered pardonable in the eyes of courtiers, the ascendency of his talents. This personal superiority indeed excited much more admiration than even the writings which proceeded from his pen, and, at the period of his reception in the Academy, was made the subject of eloquent commendation. "On sent," says La Bruyère, writing of him soon afterwards, "la force et l'ascendant de ce rare esprit, soit qu'il prêche de génie et sans préparation, soit qu'il prononce un discours étudié et oratoire, soit qu'il explique ses pensées dans la conversation ; toujours maître de l'oreille et du cœur de ceux qui l'écoutent, il ne leur permet pas d'envier ni tant d'élévation, ni tant de faculté de delicatesse de politesse." This ascendency of virtue, of grace, and of genius, which excited in the hearts of the friends of Fénélon a tenderness mixed with enthusiasm, and which had even won Madame de Maintenon, in spite of her distrust and reserve, proved altogether unavailing against the prepossessions of Louis XIV. This monarch no doubt esteemed the man to whom he had confided the education of his grandson, but he never had any relish for his society. It is supposed indeed that the brilliant and ready elocution of Fénélon was distasteful to Louis, intolerant as he was of any sort of pre-eminence except his own. But if we cast our eyes on the letter in which Fénélon, in an expansion of confidence, informed Madame de Maintenon "that Louis XIV. had no idea of his duties as a king," we shall probably find, in the expression of this honest but uncourtly opinion, a better explanation of the aversion of a monarch accustomed to adulation, than in any supposed jealousy of the superiority of his conversational powers. Fénélon passed five years in the eminent situation of preceptor to the dauphin, without asking or receiving any thing; and, indeed, during his residence at court he had preserved the most irreproachable disinterestedness. Louis XIV. however, who knew how to recompense merit, even though its possessor might not be personally agreeable to himself, wished to repair this oversight, and, in 1694, named Fénélon Archbishop of Cambrai.

But at this moment of favour and prosperity his credit was destined to receive a blow, which would have inflicted a mortal wound on a less inviolable reputation. Fénélon, whose natural temperament disposed him to cherish a lively and spiritual devotion, had for some time fancied that he recognised some of his own principles in the mouth of a pious mad woman, who, not doubt, had great talents for persuasion, since she obtained an extraordinary influence over several superior minds. Madame Guyon, writing and discoursing on grace and on pure love, at first persecuted and arrested, soon afterwards admitted into the intimate society of the Duke of Beauvilliers, received by Madame de Maintenon, and authorized to disseminate her doctrine in St Cyr, then suspected by Bossuet, arrested of new, interrogated, and condemned, served as a pretext for the disgrace of Fénélon. The inexorable Bossuet, who loved not the mystical subtilties and refinements concerning divine love, with which the lively and tender imagination of Fénélon was captivated, wished to bring it about that the new Archbishop of Cambrai should himself condemn the errors of a woman who had been his friend. Fénélon, however, refused, both from conscience and delicacy, to gratify his antagonist in this particular. Fearing to compromise opinions which were dear to him, wishing to manage and restrain an unfortunate woman, whose only offence appeared to consist in some venial exaggeration about the love of God, and perhaps also shocked at the theological haughtiness of Bossuet, who pressed upon him as if for the purpose of proselytism, he stood upon the defensive, and published his *Maximes des Saintes*, which may be regarded as an indirect apology for, or even as a subdued exposition of, the principles of Madame Guyon. In an age when a religious opinion was a political event, the first appearance of this work excited murmurs of astonishment; and all those who had been secretly envious of the genius and the promotion of Fénélon, declared loudly against the errors of his theology. Bossuet, a man incapable of indulging mean or unworthy sentiments, but at the same time inflexible, impatient of contradiction, and regardless of all external observances, when he believed the faith to be compromised, denounced to Louis XIV. in the midst of his court, the alleged heresy of the Archbishop of Cambrai; and at the moment when this attack was made upon Fénélon, the burning of his palace at Cambrai, and the consequent loss of his library, manuscripts, and papers, put his patience to a new trial, yet only drew from him the touching remark, "It is better that the fire should have consumed my dwelling than the cottage of a poor labourer." Nevertheless Bossuet, committed by his declaration to the king, prepared to pursue his rival, and seemed eager to extort from him a recantation; whilst, on the other hand, Madame de Maintenon, hitherto the friend and protectress of Fénélon, treated him with the greatest coldness. In the mean time Fénélon submitted his book to the judgment of the holy see. Bossuet, however, having already composed remarks, in which bitter and vehement censure is surrounded with ostentatious expressions of friendship and regret, proposed a conference; but this Fénélon declined, preferring to defend his book at the tribunal to which he had appealed. It was then that he received orders to quit the court and retire into his diocese; a circumstance which occasioned great grief to the Duke of Burgundy. The cabal wished to profit by the fall of Fénélon to overthrow the Duke of Beauvilliers; but the latter was saved by his own virtuous conduct; for his devotion to the cause his unfortunate friend interested the generosity of Louis XIV. and their design miscarried. Notwithstanding the evident desire of this monarch, however, the court of Rome hesitated to condemn an archbishop so illustrious as Fénélon. But the repugnance evinced by Innocent VIII. only served to stimulate the talents of the accuser and accused; and, whilst the judges (a commission consisting of ten cardinals) remained undecided, the writings of the two adversaries succeeded one another with prodigious rapidity. The contest had, in fact, now changed its character. After having exhausted the dogma, Bossuet threw himself upon the facts; and the *Relation du Quiétisme*, written with equal spirit and malignity, seemed calculated to involve Fénélon in a portion of the ridicule which inseparably attached to Madame Guyon. The Abbé Bossuet, an unworthy nephew of the Bishop of Meaux, extended still further these personal inculpations, and, having collected some odious rumours, sought to impeach the purity of Fénélon's character. Never did the indignation of a virtuous and calumniated spirit display itself in greater eloquence. Fénélon, in his defence, demolished these vile accusations; and it required new letters from Louis XIV. prepared by Bossuet, and new intrigues, carried even to the extent of menace, to extort from the court of Rome a reluctant condemnation, which, when obtained, was found to be softened both in the form and in the expressions.[1] But the long and glorious resistance of the Archbishop of Cambrai had exasperated to the utmost the resentment of Louis XIV.; and the hesitation of the court of Rome to condemn him rendered his disgrace at that of France more irrecoverable than ever. When the brief, so long delayed, and obtained after so much discussion and intrigue, at length arrived in 1699, Fénélon hastened to subscribe it, and to ratify his own condemnation by a mandatory letter, conceived in the most touching and simple language, although Bossuet did not fail to discover in it much parade and ambiguity.[2]

The modest submission of Fénélon, his silence, his episcopal virtues, and the admiration which these had inspired, would not, in all probability, have re-opened to him the doors of the court of Louis XIV.; but an unexpected event, which occurred at this time, served to irritate that monarch more than ever against him. The *Télémaque*, composed several years previously during the period of his favour, was published some months after the affair about Quietism, through the infidelity of a domestic who had been employed to transcribe the manuscript, and who, it appears, had contrived to take a copy for himself. The work, though suppressed in France, was reproduced by the presses of Holland, and obtained throughout all Europe a success which malignity rendered injurious to Louis XIV., by seeking in it allusions to the conquests and misfortunes of his reign. This prince, who had always disliked the political notions of Fénélon, and had even described him as "un bel esprit chimérique," regarded the author of *Télémaque* as a detractor of his glory, who to the guilt of ingratitude added the more irritating injustice of satire. There cannot be a greater absurdity, however, than to construe this production as a political satire, or to seek in it for allegorical and premeditated censure of Louis XIV.; all the details being, in fact, combined in the best manner imaginable for disconcerting allusions, and avoiding as much as possible the inevitable fatality of resemblances. We are convinced indeed that this generous precaution occupied the mind of Fénélon whilst composing the work, and that, writing for the happiness of nations, he selected those primitive manners, and antique forms of society, which are the most remote from the picture of life presented by modern Europe, but which served equally well to embody his poetical conception, and to suggest those instructive lessons which it was his grand object to inculcate. Besides, why should he have thought of representing Louis XIV. under the character of the imprudent Idomeneus, or that of the sacrilegious Adrastus, rather than under the masterly delineation of the great and virtuous Sesostris?

Fénélon, however, soon learned the indelible impression which *Télémaque* had produced upon the heart of the king; and, resigned to his banishment from court, which he had sometimes the weakness to call his disgrace, he sought to console himself for the loss of the royal favour by endeavouring to diffuse happiness around him in his retreat at Cambrai. The sanctity of the ancient bishops, the severity of the primitive church, the attraction of the most indulgent virtue, the charm of the most captivating politeness, the utmost eagerness to fulfil even the humblest duties of the ministry, indefatigable goodness, inexhaustible charity; such are the traits of Fénélon's character as delineated by an eloquent and virtuous prelate, who knew him well, and who dwells with enthusiasm on the picture which he has drawn of his illustrious friend. The first care of Fénélon was to instruct the clergy of a seminary which he had founded; nor did he even disdain to teach their catechism to the children of his diocese. Like the bishops of ancient days, he often ascended the pulpit of his cathedral, and, trusting at once to his faith and his feelings, spoke without preparation, diffusing all the treasures of his natural eloquence. When the misfortunes of the war, which chastised the ambition of Louis XIV., brought the allied army into the diocese of Cambrai, the occasion called for new efforts and new sacrifices upon the part of the good archbishop, who, by his wisdom, his firmness, and the nobleness of his language, inspired the hostile commanders with a salutary respect for the unfortunate provinces of Flanders. Marlborough and Eugène indeed were worthy of listening to the voice of the great man whose genius and worth they so well appreciated.[3]

The situation of Cambrai on the frontiers of France attracted to the archiepiscopal residence many strangers, none of whom approached or quitted its lord without being affected with a sort of religious admiration. Not to mention Ramsay, who passed several years under his roof, the celebrated Marshal Munich, and the unfortunate Chevalier de St George, called James III., experienced the delight of his society, and derived instruction from his superior sagacity. By the wise counsels which he gave to James III., Fénélon showed his high esteem for the English constitution, powerful alike against despotism on the one hand, and anarchy on the other. The archbishop was exempt from that narrow patriotism which undervalues whatever exists beyond the frontiers. His virtuous and benevolent spirit

---

[1] The interest of this discussion, so foreign to the ideas of our age, has been admirably preserved in the excellent *History of Fénélon* by M. de Bausset, in which will be found an animated picture of the court of Rome and of the court of France, which took such a lively interest in this frivolous question, which, however, was aggrandized by the opinions of the time, and the prodigious talents of the rival disputants.

[2] Pope Innocent, who appears to have heartily disapproved the violent proceedings adopted against the Archbishop of Cambrai, wrote thus to the prelates who had particularly distinguished themselves as adversaries of Fénélon: *Peccavit excessu amoris divini, sed vos peccâstis defectu amoris proximi*; one of the most pungent reproofs, perhaps, which is to be found in all history.

[3] It is now known that the *Vie du Prince Eugène*, though written as if it were an autobiography in the first person, is the production of the Prince de Ligne. In this clever performance, the veteran is made to speak thus of the great preachers of his time: "Quand Bourdaloue me fait tout craindre, Massillon me fait tout espérer. Nous sommes nés la même année, et je l'ai connu à son entrée dans le monde, parfaitement aimable. Bossuet m'étonne; Fénélon me touche. Je les avais vus aussi dans ma jeunesse; et Marlborough et moi, nous avons rendu *au dernier* tous les honneurs possibles, quand nous avons pris Cambrai." (*Vie du Prince Eugène*, p. 225. Paris, 1810, 8vo.)

concerned itself for the welfare of the whole human family. "I love my family," said he, "better than myself; I love my country better than my family; but I love the human race better than my country." The humanity of Fénélon was not, however, confined to exaggerated speculations and impracticable generalities, which always suppose great ignorance of the details of human affairs. His politics were not the dream of a virtuous but fanciful mind. He had seen and judged both the court and the world; he was acquainted with the history of all ages; and he was endowed with an independence of spirit which raised him above the prejudices of his age and nation. In the different memoirs which he addressed to the Duke of Beauvilliers may be seen proofs of the wisdom of his views respecting the greatest interests, particularly the succession to the throne of Spain, the policy best suited to Philip V., the views of the allies, the conduct of the war, and the necessity of peace. The disastrous war of the succession having brought the theatre of action near to the archiepiscopal residence of Fénélon, afforded him an opportunity, after ten years' absence, of seeing the young prince whom he had formed, and who had just assumed the command of the French troops. It cannot be disguised, however, that, in the command of armies, the pupil of Fénélon fell far below the promise of his youth and the opinion of France respecting him. The letters of the archbishop to the Duke of Burgundy, at this decisive epoch, evince a severe frankness, and show the ascendency which the master had acquired over the mind of the scholar; so much so, indeed, as to create a suspicion that the young prince, though well informed, docile, and virtuous, was of too timid a genius. In these letters also severe judgments are pronounced on all the generals who then formed the hope of France. Fénélon, in fact, though he possessed great sweetness of disposition, had not a little of domination in his character. His ideas were absolute and decisive; the promptitude and force of his mind rendered his judgments energetic and inflexible. But the continual attention which he gave to the political interests of France in no degree diminished his zeal for the affairs of religion and the church; and those who have been accustomed to honour him as a philosopher, will perhaps be surprised to find him entering into all ecclesiastical discussions with an ardour equal to that of Bossuet himself. When the unfortunate disputes about Jansenism were, after a long interruption, revived, Fénélon wrote against men who did not imitate him in his respect for the court of Rome, and he soon found himself engaged in a controversy scarcely less animated than that which had taken place concerning Quietism.

The courtiers supposed that in acting thus Fénélon had views of ambition and flattery. But if he had desired to regain the favour of the sovereign, he employed, about the same period, a much more effectual method for accomplishing his object, by feeding at his own expense the whole French army during the disastrous winter of 1709. His aim in both cases was to serve religion and his country. The same sentiments dictated the view which he presented the following year of the evils of France, and also the project of associating the nation with the government, by convoking an assembly of the notables, a proposition remarkable in itself, and still more so when considered in connection with subsequent events. In the memoir which contains the exposition of this scheme, Fénélon shows that he had rightly estimated the strength and the weakness of despotism, as well as the salutary power of liberty. Meanwhile, an unexpected event appeared to accelerate the moment when the counsels of Fénélon were to govern France. The grand dauphin died, and the Duke of Burgundy, long oppressed by the mediocrity of his father, saw himself all at once brought close to the throne of which he was heir, and to the king, whose stay and support he now became. His virtues, freed from a jealous tutelage, had at length scope for action; and the pupil of Fénélon showed himself worthy of his master. Full of hope and joy, the latter wrote to the young prince, who, according to St Simon, reigned in advance, "Il ne faut pas que tous soient à un seul, mais un seul doit être à tous pour faire leur bonheur;" language which, we believe, has but rarely been addressed to the heirs apparent of thrones. But whilst Fénélon was devising plans for promoting the welfare of France, and advancing the glory of its future sovereign, all his hopes were blasted by the sudden death of the young heir of the old king, who remained unshaken amidst all the humiliations of his glory, and all the disasters of his family. Fénélon survived this event some time, and, notwithstanding his grief, laboured to prevent the evils incident to a long and inevitable minority. In several confidential memoirs which he wrote on this subject, we discover the novelty of his political views, and that spirit of liberty which, in his age, was not the least of its innovations. One of these papers is devoted to a discussion of the probabilities of the guilt of the Duke of Orleans, and whether he was actuated by an ambition which required other crimes besides that which had been laid to his charge; a memoir in which, without dwelling upon all the horrors of the popular reports, he judges severely the scandalous profligacy of the Duke of Orleans, and condemns his vices in the tone and language which it became a Christian bishop to assume. The last public discussion in which Fénélon engaged related to the bull *Unigenitus*, which, as is well known, gave rise to much controversy, and occupied his attention towards the close of his life. Malignity has supposed that the zeal of Fénélon in this matter was sharpened by an old grudge against the Cardinal de Noailles; but when the conduct of this virtuous and excellent man seems to be authorized by his duty, it is not necessary to explain it by reference to his alleged weaknesses. Faithful above all things to his episcopal character, he conceived himself bound to combat errors which he considered as calculated to disturb the consciences of men, and to interrupt the repose of the church. But his wine of life was now upon the lees. His friends, like the travellers on the bridge in the Vision of Mirza, had dropped off one by one, till the Duke of Beauvilliers alone remained to him; and when the latter was also removed by death, Fénélon followed him to the grave at the brief interval of four months. This great and good man expired on the 7th January 1715, at the age of sixty-four; and his death, which a slight fall had accelerated, was, like his life, that of a virtuous and exemplary Christian bishop. In the *Dissertations* prefixed to this work (vol. i. p. 335) the reader will find the characters of Fénélon and Bossuet ably contrasted, by Sir James Mackintosh.

The following list of the works of Fénélon includes every thing of any consequence which proceeded from his pen: 1. *Traité de l'Education des Filles*, 1681 and 1687; 2. *Traité du Ministère des Pasteurs*, 1688, in 12mo; 3. *Explication des Maximes des Saints*, 1697, in 12mo; 4. *Aventures de Télémaque*, 1699, the editions of which are innumerable; 5. *Dialogues des Morts, composés pour l'éducation d'un Prince*, 1712, in 12mo; 6. *Dialogues sur l'Eloquence en général, et sur celle de la Chaire en particulier, avec une Lettre à l'Académie Française*, 1718, in 12mo; 7. *Examen de la Conscience d'une Roi*, 1734; 8. *Lettres sur divers sujets, concernant la Religion et la Métaphysique*, 1718; 9. *Démonstration de l'Existence de Dieu, tirée de la connaissance de la Nature, et proportionée à la faible intelligence des plus simples*, 1713, in 12mo; 10. *Recueil de Sermons choisis sur différents sujets*, 1710, in 12mo; 11. *Œuvres Spirituelles*. There is no very complete edition of the works of Fénélon. The clergy of France undertook one some years before the Revolution, and entrusted the preparation of it first to the Abbé Gallard, and afterwards to the Abbé de Querbeuf; but, from whatever cause, in this collection of the writings of Fénélon, which appeared at Paris in nine volumes 4to, 1787–1792, the reader will seek in vain for those on Quietism and Jansenism, his *Explication des Maximes*, and his *Mandements*. In the edition of the *Œuvres de Fénélon*, published at Toulouse, 1809–1811, in nineteen vols. 12mo, the life of Fénélon by Querbeuf has been introduced, together with four *Instructions Pastorales*, and an *Abrégé des Vies des anciens Philosophes*, which are not contained in the former edition. Some years after the death of Fénélon there appeared *Recueil de quelques Opuscules de M. de Salignac de Lamotte-Fénélon, archevêque de Cambrai, sur différentes matières importantes*, in 8vo, a rare volume, which is precious as containing a detailed catalogue or notice of all his works, reprinted in the edition of *Les Aventures de Télémaque* published at Lyons in 1815. The éloge of Fénélon by D'Alembert will be found in the *Histoire des Membres de l'Académie Française* (tom. i. and iii.). That of Laharpe gained the prize proposed by the Academy, whilst the abbe obtained the *accessit*. But the most complete biographical account of this illustrious man is that given by M. de Bausset, formerly bishop of Alais, in his *Histoire de Fénélon*, 1808, in 3 vols. 8vo, reprinted the year following with corrections and additions. (A.)

FENTON, Sir Geoffrey, an eminent writer and statesman during the reigns of Elizabeth and James I., was brother to Edward Fenton, the navigator, who accompanied Sir Martin Frobisher in his expeditions, and was afterwards sent out independently to endeavour to discover a north-west passage. The time of Sir Geoffrey's birth is uncertain, but he appears to have received a liberal education, and certainly gave many proofs of his acquaintance with ancient and modern learning, particularly of his knowledge of the French, Spanish, and Italian languages. He is best known, however, for his translation of the *History of the Wars of Italy* by Guicciardini, which he dedicated to Queen Elizabeth. But this was his last work, as is proved by the date of the dedication (7th January 1579) just mentioned. He had previously published, 1. Certain Tragical Discourses, written oute of French and Latin, 1567, in 4to; 2. An Account of a dispute at Paris, between two Doctors of the Sorbonne and two Ministers of God's Word, 1571; 3. An Epistle, or Godly Admonition, sent to the Pastors of the Flemish Church at Antwerp, exhorting them to concord with other Ministers; translated from the original of Antonio de Carro, 1578; 4. Golden Epistles, containing variety of Discourses, both moral, philosophical, and divine, gathered as well out of the remainder of Guevara's works, as other authors, Latin, French, and Italian, 1577. The familiar epistles of Guevara had been published in English by Edward Fellowes, in 1574; but Fenton's collection consists of pieces not contained in that publication, and, like his translation of Guicciardini, has risen in public estimation since the language and literature of the Elizabethan age have been more generally studied. In the capacity of queen's counsellor or secretary, Fenton served for a considerable time in Ireland, where his conduct appears to have given great satisfaction to his royal mistress, and whence he was frequently sent for to be consulted respecting Irish affairs. Nor does the confidence which his sovereign had in his judgment and understanding appear to have been misplaced. Maintained in office by her favour alone, he repaid her kindness by communicating salutary truths, and recommending wise and liberal measures. To his honour be it stated, he took every opportunity of impressing on the mind of the queen the important truth, that the Irish were to be governed only by a strict observance of the rules of justice, and that the safety and glory of her government in that island depended on her subjects enjoying the protection of equal laws. How much misery, and suffering, and humiliation, might have been spared to Ireland, if succeeding counsellors and secretaries in that country had been capable of appreciating the enlightened policy so strongly recommended by Fenton! In 1603 Sir Geoffrey married his only daughter to Mr Boyle, afterwards Earl of Cork, and died at his house in Dublin on the 19th October 1606. (A.)

Fenton, *Elijah*, an English poet of considerable note, was born at Shelton, near Newcastle-under-Line, in Staffordshire, on the 20th May 1683. Being the youngest of twelve children, he was destined for the church as a profession; and with this view, after passing through the usual course of grammatical education, he was, on the 1st July 1700, admitted a pensioner of Jesus College, Cambridge, where he prosecuted his studies with much diligence and assiduity; but having refused to take the oaths to government, he was obliged to quit the university without a degree, and forced to trust to his abilities for a subsistence. Whatever were the difficulties and discouragements which he had to struggle with, however, Fenton never descended to mean or dishonourable shifts; and as his conduct was without reproach, so his name was never mentioned except with commendation. His first employment promised more than it afterwards realized. He accompanied the Earl of Orrery to Flanders in the capacity of private secretary, and returned with his lordship to England in 1705. Being thus left without employment, he became assistant in a school at Headley, in Surrey, and was soon afterwards appointed master of the free grammar-school at Sevenoaks in Kent. In 1710 he was prevailed on to give up the drudgery of teaching, for the worse drudgery of political dependence; Lord Bolingbroke, who had persuaded him to take this unwise step, having, with characteristic recklessness, neglected his interest, and left him disappointed and in debt. But not long afterwards he was appointed tutor to Lord Broghill, only son of the Earl of Orrery; and when this engagement expired, he was, on the recommendation of Pope, employed to give private instructions to Mr Craggs, secretary of state, who, feeling his own want of literature, was anxious, with the aid of such an instructor, to supply the deficiencies of his education. The sudden death of Craggs, however, disappointed the expectations which had been formed from this connection, and Fenton was again thrown out of employment. His next engagement was with Pope himself. The success of the translation of the Iliad having induced the latter to undertake that of the Odyssey, he, in order to lighten the task, resolved to engage auxiliaries; and, with this view, retaining twelve books for his own share, he distributed the remaining twelve between Broome and Fenton. Of these, according to Johnson and Warton, Fenton translated the first, fourth, nineteenth, and twentieth; though the Earl of Orrery has asserted that he translated double the number of books which Pope has acknowledged.[1] In 1723 his tragedy of *Mariamne* was brought out, and performed with such success that the author's profits are said to have amounted to nearly a thousand pounds. The poetical merit of this tragedy is considerable; but the

---

[1] In a letter to Mr Duncombe, Lord Orrery says, "His reward was a trifle, an arrant trifle. He has even told me that he thought Pope feared him more than he loved him. He had no opinion of Pope's heart; and declared him, in the words of Bishop Atterbury, "*Mens curva in corpore curvo.*"

diction is too figurative and ornate for a dramatic composition, and accordingly it has not retained its place on the stage. In 1727, Fenton superintended a new edition of Milton's *Poems*, to which he prefixed a life, of which Johnson has spoken with commendation; and, in 1729, he published a splendid edition of Waller, with notes, which is accounted among the best of that poet's works. The latter part of Fenton's life was passed in tranquillity. By the recommendation of Pope, Lady Trumbull appointed him tutor to her son, first at home, and afterwards at Cambridge; and when he had acquitted himself of the duties of this office, she still retained him in her family as auditor of her accounts, in which capacity he seems to have enjoyed his ease, and found leisure to pay frequent visits to his literary friends in London. He died at East Hampstead, Berkshire, on the 13th July 1730, and was interred in the parish church, where his tomb bears inscribed on it an epitaph written by Pope. Fenton, naturally indolent, was capable of greater things than he performed. His reputation as a poet rests chiefly on his *Mariamne*, and his share in the translation of the *Odyssey*, which the readers of poetry have never been able to distinguish from the portion executed by Pope himself; but to his *Miscellaneous Poems*, published in 1717, he has been indebted for a place amongst the English poets in Dr Johnson's collection. Of his morals and conversation the account is uniform. "He was never named," says Dr Johnson, "but with praise and fondness, as a man in the highest degree amiable and excellent. Such was the character given of him by the Earl of Orrery, his pupil; such is the testimony of Pope; and such were the suffrages of all who could boast of his acquaintance." (A.)

FEOD, or FEUD. See FEUDAL LAW.

FEODOSIA, one of the circles into which the Russian province of Taurida is divided. It stretches along the eastern side of the peninsula which separates the Black Sea from the Sea of Azoph. It is a fertile tract of land, and was formerly much more thickly peopled, and much better cultivated, than it is at present. The chief place, known before the Russian possession by the name of Kaffa, but now by that of the province, is situated on a bay in the Black Sea, and has an excellent harbour, though not safe in the winter. It contains from 400 to 500 houses, and about 4500 inhabitants. It was declared a free port in 1806, since which period its inhabitants and trade have greatly increased. It is situated in latitude 45. 4. N. and longitude 35. 14. E.

FEOFFMENT, in *Law* (from the verb *feoffare* or *infeudare*, to give one a fief), the gift or grant of any corporeal hereditament to another. He who so gives, or enfeofs, is called the *feoffer*, and the person enfeoffed is denominated the *feoffee*.

FERALIA, in *Antiquity*, a festival observed amongst the Romans on the 21st February, or, according to Ovid, on the 17th of that month, in honour of the manes of their deceased friends and relations.

Varro derives the word from *inferi*, or from *fero*, on account of a repast carried to the sepulchres of such as had that day the last offices rendered to them. Festus derives it from *ferio*, on account of the victims sacrificed. Vossius observes that the Romans called death *fera*, cruel, and that hence might arise the word *feralia*. Macrobius (*Saturnalia*, lib. i. cap. 13), refers the origin of the ceremony to Numa Pompilius. Ovid, in his *Fasti*, goes back for its institution as far as the time of Æneas. He adds, that on the same day a sacrifice was performed to the goddess Muta, or Dumb; and that the persons who officiated were an old woman and a number of attendant young girls.

During the continuance of this festival, which lasted eleven days, presents were made at the graves of the deceased, marriages were forbidden, and the temples of the gods were shut. Whilst the ceremonies continued, it was imagined that the ghosts suffered no punishments in hell, but that their tormentors allowed them to wander round their tombs, and to feast upon the meats which their surviving friends had prepared for them.

At the feralia public feasts were sometimes given to the people, at the tombs of the rich and great, by their heirs or particular friends.

FER DE FOURCHETTE, in *Heraldry*, a cross having at each end a forked iron, like that formerly used by soldiers to rest their muskets on. It differs from the cross fourche, the ends of which were bent as well as forked; whereas, this has the same sort of fork fixed upon the square end. See HERALDRY.

FERAH, a town of Persia, in the province of Seistan, ninety miles north-north-east of Zareng, and a hundred and fifty west of Candahar. Long. 62. 22. E. Lat. 33. 20. N.

FERE, LA, a town of the department of the Aisne, in France, at the junction of the rivers Serre and Oise. It is strongly fortified, and has in it an establishment for educating artillery officers. It contains 436 houses, and 2604 inhabitants. Long. 3. 13. E. Lat. 49. 40. N.

FERENTARII, in Roman antiquity, were auxiliary troops, lightly armed, whose weapons were a sword, a bow and arrows, and a sling

FERETRIUS, a surname of Jupiter, *a ferendo*, because he had assisted the Romans; or *a feriendo*, because he had conquered their enemies under Romulus. He had at Rome a temple built by Romulus, to which the spoils called *opima* were always carried.

FERETRUM, amongst the Romans, the bier used in carrying out the bodies of the dead, a duty which was performed by the nearest male relations of the deceased. Thus, sons carried out their parents, brothers their sisters, and so on.

FERG, or FERGUE, FRANCIS PAUL, a landscape painter, was born at Vienna in 1689, and there learned the first principles of his art. He successively practised under Hans Graf, Orient, and Thiele. The last of these, who was painter to the court of Saxony, having invited him to Dresden to insert small figures in his landscapes, Ferg repaired to that city, whence he proceeded into Lower Saxony, and painted for the Duke of Brunswick and for the gallery of Salzdahl. From Germany he passed over to London, where he might have lived in esteem and affluence, if, by an indiscreet marriage, he had not been so effectually depressed, not to say degraded, that he was ever afterwards involved in difficulties. The necessities which arose out of his domestic troubles compelled him to diminish the prices of his paintings in order to procure immediate subsistence; and as these necessities increased, his pictures sunk still more in price, though not in intrinsic value. By a series of misfortunes, however, he became overwhelmed in debt, and, to avoid the pursuit of his creditors, was constrained to secrete himself in different parts of London. He died suddenly in the street one night as he was returning from some friends, about the year 1738, before he had attained his fiftieth year, and left four children wholly destitute. This pleasing artist, Mr Walpole observes, had formed a manner of his own from various Flemish painters, though resembling Poelemburg most in the enamelled softness and mellowness of his colouring; but his figures are greatly superior, every part of them being sufficiently finished, and every action expressive. He painted small landscapes, fairs, and rural meetings, with much natural truth; his horses and cattle are not inferior to those of Wouvermans; and his buildings and distances seem to owe their respective softness to the intervening air, not to the pencil. More faithful to nature than Denner, he knew how to omit exactness, when the result of the whole demanded less precision in parts. The greater number of his works are in London and Germany; and the price they now bear is the best proof of their real merit. He also etched well with aquafortis; and his prints of that description are generally esteemed by the curious.

FERGUSON, Adam, LL.D., a distinguished philosopher and historian, was born at Logierait, in the Highlands of Perthshire, on the 20th of June 1723. His father, the Reverend Adam Ferguson, a native of the neighbouring parish of Moulin, had been minister of Crathie and Braemar, in Aberdeenshire, from 1700 to 1714; but, on the eve of the rebellion under the Earl of Mar, had been translated to Logierait, where he passed the remainder of his long life, discharging the duties of his laborious charge with such exemplary piety, fidelity, and firmness, that, though at the period of his induction the parishioners were almost universally hostile to presbyterian principles, he speedily secured the respect and admiration of all ranks; and, till the close of his incumbency in 1754, retained a degree of influence which proved that his knowledge of mankind was not inferior to his zeal for their religious improvement. This excellent man left a numerous family, of whom Adam was his youngest son, by Mary Gordon, daughter of Mr Gordon of Hallhead, in Aberdeenshire.

It is believed that Adam received the first part of his education at the village school of his native parish, under the superintendence of Mr John Connacher, of whose literary attainments little can now be ascertained. Whatever may have been the merits of this teacher, they do not seem to have been estimated so highly as those of the schoolmasters of Dunkeld and Perth; to one or other of which places it was at this time customary for the parishioners of Logierait to send such of their sons as they wished to prepare for a course of academical study. Two, at least, of Mr Ferguson's younger sons attended the grammar-school of Perth, between the years 1732 and 1738, whilst Mr James Martin was rector, and Mr Andrew Cornfute one of the assistants. Under the tuition of these able and diligent instructors, Adam is said to have made uncommon progress in classical literature; and in addition to the benefit which he derived from his teachers, he possessed the advantage of living under the protection of a respectable citizen, Mr William Ferguson, his relative, a merchant in the town, and at one time chief magistrate or provost.

Towards the end of autumn 1738, when he had entered into his sixteenth year, he was removed from school to the University of St Andrews, where his father had commenced his studies fifty years before, under a very meritorious regent, Mr John Row, son of the minister of Ceres; who, being grandson of the well-known David Ferguson, minister of Dunfermline, was induced, by the claims of kindred as well as of duty, to pay particular attention to the improvement of a youth whom he soon discovered to be highly deserving of his favour. It so happened that one of the colleagues of Mr Row was still a master of St Leonard's College, and that all the other masters were of nearly the same standing with the elder Mr Ferguson, who was thus confirmed in his preference of the college in which he had prosecuted his own philosophical studies. At this very juncture the principal of St Leonard's College died, and the other professors, at whose almost unanimous recommendation Mr Tullideph was appointed to the vacant chair, anticipated the most prosperous results from his efforts to promote the good of an establishment which they considered as having fallen into disrepute, in consequence of the feeble and undignified administration of his predecessors.

The Greek class in St Leonard's College was at this time taught with great reputation by Mr Francis Pringle, who had obtained his office in 1699; but, though no other teacher of that language in Scotland could pretend to rival him, the average number of students who were received annually under his charge, from 1738 to 1747, did not exceed eleven; whilst the average of entries to the corresponding class in St Salvator's College scarcely amounted to six. Adam Ferguson was enrolled in Mr Pringle's class as a ternar, the same rank of students which, in the days of Buchanan, was characterized by the term *pauper;* that is to say, one who pays the lowest rate of fees. It has been alleged that Ferguson, after a comparative trial, was admitted one of the foundation bursars, having stood first in the list of successful competitors. If it were so, the victory was not very splendid, as, of the twelve who entered the class along with him, not more than eight (being of the denomination of ternars) could have been permitted to take a share of the contest.

Besides Pringle, the other masters in St Leonard's College were, John Craigie, admitted professor of philosophy in 1691; Ninian Young, professor of humanity, and Henry Rymer, professor of philosophy, both admitted in 1709; and David Young, professor of philosophy, admitted in 1716. Before the end of the session 1739, Charles Gregory, professor of mathematics, resigned in favour of his son David, who, though a very ordinary man, was the most popular teacher of geometry ever known in that university, which had many years before numbered amongst its professors the inventor of the reflecting telescope.

The method of teaching in St Leonard's College at this period did not materially differ from that which had been pursued in the former century. The professors in general followed the beaten track in which they had been guided by their predecessors; and the tasks which they exacted from the students were little more than exercises of memory. A young man of slender abilities might easily distinguish himself as much as his most ingenious associates, who, on the other hand, might be apt to underrate acquirements which were more accessible to plodding industry than to original talents. We have good reason to believe that Ferguson acquired little more at this seminary than a high admiration of the Grecian and Roman literature, to the beauties of which he was more nearly introduced than he had hitherto been; and that his advances in the knowledge of philosophy were all made at a subsequent period. Even under the vigilant and severe inspection of Principal Tullideph, the discipline of the college was by no means effective; and, in Mr Pringle's class particularly, some of the young gentlemen conducted themselves so improperly as to have narrowly escaped the disgrace of being refused their degrees, after they had undergone the usual trials. Mr Ferguson obtained the degree of master of arts on the 4th of May 1742, when he had nearly completed his nineteenth year. The regent under whom he finished his course of physical study was Mr David Young, who used as a text book Keill's *Introductio ad veram Physicam.*

The minister of Logierait had attempted to induce some of his other sons to follow his own profession; but as they had all testified a disinclination to this line of life, he determined to breed his youngest son to the church, and accordingly he was sent to the divinity hall at St Andrews, in November 1742, when the theological department of study was superintended by Principal Murison and Professors Shaw and Campbell, the last of whom, a man of talents and learning, was well known by his writings; but, like several of his predecessors in the same chair, he scarcely ever lectured at all. Mr Ferguson studied also a year or two at Edinburgh under Professors Gowdie and Cuming; but his attention appears to have been chiefly given to pursuits not immediately connected with his clerical views.

In the year 1745, when he had attended divinity only one half of the usual period, an appointment was offered to him, which he could not hold without ordination. It was, in fact, represented to the General Assembly that Lord John Murray, colonel of the Highland regiment (the 42d), was desirous of having a chaplain of the communion of the Church of Scotland possessed of the Erse language; and that Mr Adam Ferguson, though he had not studied divinity for the full period of six years, was pitched upon for that office, provided the Assembly would allow the presbytery of Dunkeld to take him on trials. The Assembly, in respect of the young man's capacity and good character, authorized the presbytery to ordain him on passing his first trials, and accordingly he was ordained at Dunkeld, on the 2d of July 1745. A few days afterwards he joined the regiment, in which he continued to serve till 1757; about the beginning of which year he was elected keeper of the Advocates' Library, on the resignation of the celebrated David Hume. About a year after, Mr Ferguson was succeeded in this office by Mr William Wallace, junior, advocate.

In the course of the year 1757, Mr Ferguson rendered himself conspicuous by the interest which he took in the success of the tragedy of *Douglas*, written by his friend Mr Home. He published a defence of the *morality of stage plays*, which, though its merit is not of the highest order, was admitted by the opposite party to be "the only piece on that side that was written with any tolerable degree of discretion." After Mr Home resigned his living in June 1757, Mr Ferguson and he retired to country lodgings at Braid, in the neighbourhood of Edinburgh, where they spent several months in a course of laborious study, enlivened by the intercourse of friendship. As Mr Ferguson's campaigning habits had reconciled him to a migratory life, it is not easy to trace him through all his changes of residence. During his father's lifetime he had great satisfaction in making occasional excursions to the Highlands, and thinking aloud in his solitary walks, amidst the lakes and forests of Rannoch, or on the summit of his native mountains, where one of the most magnificent prospects in nature was displayed before his eyes. It was here that the lofty enthusiasm of his spirit was nursed and matured; and it was not so much in the intercourse with polished society as in the wilds of Athole that he acquired that dignity and ease of manner for which he was distinguished above most of the literary men of his country. To use his own expressive words: "If I had not been in the Highlands of Scotland, I might be of their mind who think the inhabitants of Paris and Versailles the only polite people in the world. It is truly wonderful to see persons of every sex and age, who never travelled beyond the nearest mountain, possess themselves perfectly, perform acts of kindness with an aspect of dignity, and a perfect discernment of what is proper to oblige. This is seldom to be seen in our cities or in our capital; but a person among the mountains, who thinks himself nobly born, considers courtesy as the test of his rank. He never saw a superior, and does not know what it is to be embarrassed. He has an ingenuous deference for those who have seen more of the world than himself; but never saw the neglect of others assumed as a mark of superiority."

In the year 1759 he was elected professor of natural philosophy in the University of Edinburgh, in the room of Dr John Stewart. He had not made physical science the principal object of his inquiries; and indeed he had not studied it much more attentively than most young men do in the common routine of academical instruction. But with only four months to prepare for the labours of the winter, he qualified himself so well as to give universal satisfaction. He conducted this branch of education five years, and by adapting his lectures to the capacities of the young, contrived to render the study more interesting than it had been commonly considered. At this time he was a member of the well-known *Select Society* of Edinburgh, instituted in 1754, for the purpose of promoting philosophical discussion, and training the members to the practice of public speaking. The ardour of this society did not begin to languish till the year 1762, when another association, equally celebrated, was formed by the literary circle of Edinburgh, the design of which was to rouse the country to demand from the legislature the establishment of a militia in Scotland. Mr Ferguson may almost be considered as the founder of this society; and it was at his suggestion that it received a name (*The Poker*) which was sufficiently significant in the ears of the initiated, but utterly unintelligible by strangers. His satirical pamphlet entitled *The History of Sister Peg*, was intended to forward the object of this patriotic society; and it is perhaps the only production connected with that cause, which, at this distance of time, is capable of exciting any interest.

In 1763 Mr Ferguson was applied to by the Earl of Warwick, to take charge of his two younger sons, the Honourable Charles and Robert Greville, whose eldest brother, Lord Greville, had received part of his education under the eye of Principal Robertson. These young gentlemen resided some years in his house, and both they and their tutor Mr Macpherson repaid his attention to their improvement by the warmest affection and gratitude. Lord Warwick, who had been advised by General Clerk to place his sons under Mr Ferguson's care, was not insensible of the "great benefit they had reaped from his tuition, and advantageous as well as manly and friendly conversation." Mr, afterwards Sir John, Macpherson, at the same time acknowledged, that "to him he owed all his knowledge, as well as all his success in life."

On the appointment of Mr Balfour to the professorship of the law of nature and nations in 1764, Mr Ferguson was elected by the magistrates of Edinburgh to succeed him in the chair of moral philosophy. This had long been a favourite object of his ambition; and about ten years before, when the able and accomplished Mr Cleghorn was on his death-bed, he urged his young friend to apply for the office, which, in his apprehension, no man was more capable of adorning. Mr Cleghorn, after expressing his regret at having no such influence with the patrons as to secure such an arrangement, added, as Mr Ferguson sometimes related with much emotion, "I can only say of you, as Hamlet did of Fortinbras, *He has my dying voice.*"

Mr Ferguson entered on his new duties with a degree of spirit and activity, from which the most splendid results were to be anticipated. In one particular his mode of lecturing was singular, and not easily imitated. After having delineated the general plan of his course, and committed it to writing, he resolved not to write a system of lectures, but to endeavour to make himself master of every part of his subject, and to trust to the moment of delivery for the expression of his sentiments. This method of discoursing was in his hands very happily executed; but its success depended, in a great measure, on the state of his health and spirits, as well as upon the interest excited by the different subjects of discussion. Perhaps no lecturer, with the exception of his immediate successor, was ever more admired. His class was crowded by great numbers of gentlemen of high rank and official station, as well as by younger students. In the mean time, eagerly as he applied to the discharge of his professional duties, his attention was extended to other branches of inquiry; and within little more than a year after he commenced his labours as a lecturer on morals, he sent to the press his *Essay on the History of Civil Society*, a work which was received with an expression of public approbation which even exceeded the high expectations of his friends. "Ferguson's book," says Mr Hume, writing to Dr Robertson from London, "goes on here with great success." Gray the poet says, "There are uncommon strains of eloquence in it; and I was surprised to find not one single idiom of his country (I think) in the whole work." Mr Hume, in a letter to the author, (dated 10th March 1767), congratulates him on the success of the book, adding that he had "met with nobody that had read it who did not praise it. Lord Mansfield is very loud to that purpose in his Sunday societies. I heard Lord Chesterfield and Lord Lyttleton express the same sentiment; and, what is above all, Caddel, I am told, is already projecting a second edition of the same quarto size." Mr Hume then informs him, that Lord Shelburne and Lord Bute were amongst his most zealous partisans; the last declaring the book one of the best he had ever read. Charles Townshend appears to have been of the same opinion, as he read it five times.

General Clerk had pressed the author to dedicate his work to Lord Shelburne, who had signified his intention of offering Mr Ferguson the government of West Florida; upon which occasion his lordship laughed very heartily, when the general expressed his conviction that Mr Ferguson was more usefully employed as a teacher of science. The book, however, appeared without any dedication. In the course of the following year, Lord Shelburne intimated a hope of getting Mr Ferguson established with a proper appointment at Oxford; and some other persons of influence meditated a design of employing him in one of the departments of state. This purpose was frustrated in all probability by a temper which did not permit him to accommodate himself to the views of those whose maxims of conduct he did not entirely approve. Another circumstance may be considered as having also operated to obstruct the fulfilment of the schemes which were devised for his advancement. At this time he married Miss Burnet, a young lady nearly connected with his mother's family, and still more nearly related to his intimate friend Dr Black. Soon afterwards he began to cultivate a farm in the parish of Currie, and, at a considerable sacrifice of private interest, gratified his taste for improvement, by transforming a barren heath into a scene which became distinguished for beauty and fertility.

It was impossible, however, for any combination of circumstances to abate his literary activity; and he not only continued to conduct the business of his class with unremitted diligence, but seized every interval of leisure which he could command, to collect materials for a history of the Roman commonwealth. Whilst he was proceeding in his researches, he was solicited by Philip, Earl of Stanhope, the editor of Dr Robert Simson's posthumous works, and the other guardians of Charles, Earl of Chesterfield, to superintend the education of that young nobleman, then in his nineteenth year. The negotiation was conducted through the mediation of Dr Adam Smith, who, judging the offer to be advantageous to his friend, exerted himself with great earnestness to induce him to accept it. Lord Stanhope was extremely anxious to obtain the able services of Dr Ferguson without delay, as he conceived it to be of the utmost consequence to his young kinsman to be placed under the care of "a person so well qualified to complete the remaining part of his education, and to repair the neglects, omissions, and errors, which had unfortunately been committed in the former part of it." The proposal had originally been made early in the year 1773, and was renewed in December, soon after the commencement of the session of the college, when Dr Ferguson was engaged not only in teaching his own class, but also in lecturing on natural philosophy, the professorship of which had recently become vacant by the death of his relation Mr Russell. He was not able to prevail on the patrons to accept of a substitute to complete the labours of that session; but after obtaining leave of absence for the next session, he joined his young charge at Geneva in May 1774, and at first entertained hopes that his labours might prove beneficial. The connection, however, was not so agreeable as he expected, and it terminated about twelve months afterwards. In the mean time, he had very nearly been deprived of his office in the university. The town-council had, at his desire, appointed Mr John Bruce, then assistant and afterwards successor to Mr Stevenson, to teach the moral philosophy during the session 1774–1775; but before the conclusion of the session they thought fit to rescind this act, and to declare the office vacant. His friends in the university, particularly Drs Robertson, Blair, and Black, were exceedingly indignant at this proceeding; more especially as Sir John Pringle had been permitted to be several years absent; and at that very time the professors of mathematics and of the theory of medicine had both been allowed to discharge their duty by substitutes for two years without challenge or complaint. As the council, however, seemed to have determined to fill up the place by a new election, it became necessary for his friends to apply to the Court of Session to put a stop to their proceedings. "I have been much obliged," says he, in a letter to a friend, "to the general voice that was raised in my favour, as well as to the ardent zeal of particular friends. Ilay Campbell (afterwards Lord President) has given me proofs of friendship which I can never forget. Pulteney has behaved to me in every thing as he would have done at the beginning of the Poker Club. I have always been an advocate for mankind, and am a more determined one than ever; the fools and knaves are no more than necessary to give others something to do."

After his return, he continued, as formerly, to divide his time between his literary and agricultural pursuits, and engaged occasionally in the political controversies which agitated the country during the progress of the American war. Besides his pamphlet in answer to Dr Price's observations on liberty, he communicated his views from time to time to Sir William Pulteney, and other members of parliament; and when it was resolved by government to send out commissioners to quiet the disorders in the colonies, he was appointed secretary to the commission. It appears from a letter of General Putnam, dated July 1778, that the nomination of Dr Ferguson was very agreeable to the more intelligent part of the Americans, who, not without reason, were dissatisfied to find that the commissioners were fettered by restrictions, which rendered their appointment nugatory. "I am very sorry," he writes, "that the parliament of Great Britain is still so blind to their own and our interest, as to send Dr Ferguson and the rest of the worthy gentlemen over to America with limited power, and that to last only till July 1779, and then to be revoked by them if they think fit; by which means I am deprived of seeing your friend Dr Ferguson, which gives me great pain, as I always have heard of his being a gentleman of the first character for learning, good sense, and humanity." It is well known that the commissioners returned without accomplishing the object of their mission; but they had an opportunity of acquiring more useful information of the state and temper of the country than government had received in all the previous course of the contest. Whilst Dr Ferguson was absent during the session 1778–1779, his place was supplied by Mr Dugald Stewart, who, about five years afterwards, was destined to succeed him in the chair of moral philosophy.

In the year 1780 he was seized with an attack of apoplexy, which, though not violent, was nevertheless sufficient to alarm his friends for his safety. This formidable affection did not in the slightest degree impair the force of his understanding; and so abstemious did he afterwards become, as not only to secure himself against the recurrence of the disease, but to enjoy almost uninterrupted health for more than thirty years. As he could not now venture to lecture as formerly without the use of written notes, he therefore found it necessary to write out a course of instruction to be read during the remainder of his incumbency. In his endeavours to recover the substance of his lectures, he availed himself of the notes taken by intelligent young men, who had studied under him different sessions, and who might thus be expected to have preserved the various modes in which he had stated his doctrines, and the different arguments and illustrations by which he had happened to supply in one session what might have been omitted in another. But, in the prospect of soon relinquishing his office, it was scarcely conceivable that the compilation which he thus executed could possess all the excellencies which he was capable of imparting to it; more especially as he was now busy in carrying his great historical work through the press. This was the *History of the Progress and Termination of the Roman Republic*, in three volumes quarto, published in 1783, a book which not only delights by the clearness of its narrative and the boldness of its descriptions, but instructs and animates by profound and masterly delineations of character, as well as by the philosophical precision with which it traces the connection of events. It is written in that tone of high-minded enthusiasm, which, if it can only snatch from oblivion whatever is noble and generous in the record of human actions, regards the graces of style as objects merely of secondary account, and is chiefly studious of impressing the lessons of wisdom which may be gathered from the survey of distant ages.

The fatigues and anxieties of public teaching now became oppressive to his spirits, and not altogether favourable to his health; and he therefore deemed it expedient to resign his office in 1784, when he had completed his sixty-first year. Mr Dugald Stewart, then professor of mathematics, succeeded to his office; and in order to entitle Dr Ferguson to retain his salary, he was conjoined in the professorship of mathematics with Mr Playfair. He now proceeded to revise the notes of his lectures on ethics and politics, with a view to publication; and in 1792 the work appeared, under the title of *Principles of Moral and Political Science*. Though composed under disadvantageous circumstances, and though he has omitted many of the questions which were treated in his elementary course, it contains an admirable view of the systems both of ancient and modern philosophers, particularly respecting the foundations of moral approbation, and the sources of private happiness and public security. The authors to whose suggestions he was most indebted were Xenophon, Plato, and Aristotle, amongst the Greeks, Cicero and Seneca amongst the Latins, Epictetus and Antoninus amongst the later scholars of the Grecian school; and, amongst the moderns, Shaftesbury, Hutcheson, Montesquieu, and Adam Smith. It has been considered as a blameable omission in this work, that too slight notice is taken of the importance of religious principle; and the author, in fact, seems to have been aware that he had exposed himself to this objection. No man, however, was ever more anxious to establish the foundations of natural theology, and to strengthen the arguments for a future state; subjects on which the work abounds in passages of uncommon beauty.

After the publication of this work, Dr Ferguson, now in his seventieth year, resolved to pay a visit to the ancient metropolis of the world. He passed a short time at some of the principal cities of Europe, Berlin, Vienna, Florence, Naples, and Venice, and resided part of the winter 1793 at Rome, in all of which places his reception was extremely flattering. He was elected a member of the Academy of Berlin, as well as of other learned societies. Upon his return to Britain in 1794, he took up his residence at Nidpath Castle in Tweeddale, from which he soon removed to Hallyards in Manor Water. In this agreeable retreat he spent the next fourteen years of his life, a longer period than he had ever before resided in any one place. At last, however, when his sight and his hearing had in a great measure failed, he deemed it advisable to settle in a town, where he might occasionally enjoy the conversation of intelligent friends; and his early prepossessions induced him to settle at St Andrews. Here his strength gradually declined, but the vigour of his mind continued unimpaired as long as he lived. No man took a more lively interest in the great events which were then passing in the world, or contemplated more anxiously the consequences of the arduous struggle in which his country was engaged. He lived long enough to witness the triumphant issue of the contest; and after a short illness, he died on the 22d of February 1816, in the ninety-third year of his age, leaving three sons and three daughters.

In the various situations which it was his lot to occupy, he had uniformly conducted himself with a dignity and decision which bespoke the elevation and force of his mind. As a military chaplain, he happily united the strict decorum of the clerical character with the unembarrassed address of a man of the world; so that he at the same time secured the respect of the officers and the devoted attachment of the private soldiers. It was while accompanying the army on different expeditions, one of the first of which was an ill-conducted descent on the coast of Bretagne in 1745, that he applied his mind to study the art of war; and it cannot be denied that he excels particularly in the description of military evolutions. In private life his conversation was easy and elegant, and, among his intimate friends, enlivened by a fascinating gaiety and refinement of humour. He was not very patient of contradiction, however, and rather apt to testify his contempt of assumed superiority.

His writings are,

1. *A Sermon*, preached in the Erse language to his majesty's first Highland regiment of foot, commanded by Lord John Murray, at their cantonment at Camberwell, on the 18th day of December 1745. By the Rev. Mr A. F. chaplain to the said regiment, and translated by him into English for the use of a lady of quality in Scotland, at whose desire it is now published. London, 1746.

2. *The Morality of Stage Plays seriously considered.* Edinburgh, 1757.

3. *A Pamphlet on the Militia.* London, 1758.

4. *The History of the Proceedings in the case of Margaret, commonly called Sister Peg.* Three editions. London, 1762. Another, 1777.

5. *Analysis of Lectures on Mechanics.* Edinburgh.

6. *An Essay on the History of Civil Society.* London, 1767. This book has passed through many editions, and has been translated into almost all the European languages. A translation into German was published at Leipsig in 1768, under the title of *Bersuch uber die Geschichte der Burgerlichen Gesellschaft.* A French translation, by M. Bergier, was published in 1783.

7. *Analysis of Pneumatics and Moral Philosophy.* A German translation, by Mr Garve of Leipsig, is said to be well executed. Edinburgh, 1766. Fifty-five pages 12mo.

8. *Institutes of Moral Philosophy*, 1769; 319 pages 12mo. Another edition, revised and corrected, 1773; 294 pages. A translation of this edition into French was published at Geneva in 1775, and it had the advantage of being revised by the author. A third edition, enlarged, was published at

Edinburgh, 1785; 317 pages 12mo. This elementary work has been used as a text book in several foreign universities. A translation into the Russian language (from the German) was printed at Moscow in 1804.

9. Remarks on a pamphlet lately published by Dr Price, entitled *Observations on the Nature of Civil Liberty, &c.* in a letter from a gentleman in the country to a member of Parliament. London, 1776. These remarks having been addressed to Sir Grey Cooper, secretary of the treasury, were printed by his direction.

10. *The History of the Progress and Termination of the Roman Republic.* London, 1783. 3 vols. 4to. A translation into German was printed at Leipsig in 1784. It has been translated into several other modern languages, and has passed through a number of English editions, one of which was printed at Basel, in Switzerland, in 1791.

11. *Principles of Moral and Political Science,* being chiefly a retrospect of lectures delivered in the College of Edinburgh. London, 1792. 2 vols. 4to.

12. *Minutes of the Life and Character of Joseph Black, M. D.* 1801. (Published in the *Transactions of the Royal Society of Edinburgh.*)

13. *Biographical Sketch, or Memoir of Lieutenant-Colonel Patrick Ferguson.* Edinburgh, 1817. This tract, though printed, has not been published for sale.

He left behind him many papers on the subjects which had chiefly occupied his thoughts from the time of his last academical appointment; but a great mass of letters and other valuable documents had been indiscriminately destroyed by his direction some years before his death. (P. P. P.)

FERGUSON, *James*, an eminent experimental philosopher, mechanist, and astronomer, was born in Banffshire, Scotland, in 1714. His parents were very poor. At an early age, however, his extraordinary genius began to unfold itself. He first learned to read by overhearing his father teach his elder brother; and he had made this acquisition before any one suspected he had done so. He soon discovered a peculiar taste for mechanics, which first indicated itself on seeing his father use a lever; and having pursued this study a considerable time, even when very young, he at length made a watch in wood work, from having once seen one. As he had no instructor, nor any help from books, every thing he learned had all the merit of an original discovery; and such in fact he very naturally believed it to be. As soon as his age permitted he went out to service; but he met with hardships in this humble capacity, which rendered his constitution feeble through life. Whilst he was servant to a farmer, whose goodness he acknowledges in the modest account of himself which he prefixed to his *Mechanical Exercises*, he frequently contemplated the stars; and he began the study of astronomy by laying down, from his own observations alone, a celestial globe. His kind master observing these marks of his ingenuity, procured him the countenance and assistance of some neighbouring gentlemen, by whose help and instructions he went on acquiring further knowledge, and was at length sent to Edinburgh. There, having obtained some notion of drawing, he began to take portraits in miniature, by which means he supported himself and family for several years, both in Scotland and England, whilst engaged in pursuing more serious studies. In London he first published some curious astronomical tables and calculations, and afterwards gave public lectures on experimental philosophy, which he repeated in most of the principal towns in England with general approbation. He was elected a fellow of the Royal Society without paying for admission; and he had a pension of L.50 per annum given him, unsolicited, by King George III. on his accession, who had heard his lectures, and who frequently sent for and conversed with him on curious topics. He also received several presents from his majesty, and from other patrons of merit. The degree of consideration which Mr Ferguson attained by the strength of his natural genius alone is in fact known to every one. He was universally considered as at the head of astronomy and mechanics in this nation of philosophers; and he might justly be styled self-taught, or rather heaven-taught; for in his whole life he had not received above half a year's instruction at school. He was a man of the clearest judgment and the most unwearied application to study; benevolent, gentle, and innocent in his manners as a child; humble, courteous, and communicative; and, instead of pedantry, philosophy seemed to have produced in him only diffidence and urbanity. He died in 1776, at the age of sixty-two.

The following is a list of Mr Ferguson's published works: 1. Astronomical Tables, and Precepts for calculating the true times of New and Full Moon, 1763; 2. Tables and Tracts relative to several Arts and Sciences; 3. An easy Introduction to Astronomy, 1769, second edition; 4. Astronomy explained upon Sir Isaac Newton's Principles, 1772, fifth edition; 5. Lectures on select subjects in Mechanics, Hydrostatics, Pneumatics, and Optics, 1772, fourth edition; 6. Select Mechanical Exercises, with a short account of the Life of the Author by himself, 1773; 7. The Art of Drawing in Perspective made easy, 1775; 8. An Introduction to Electricity, 1775; 9. Two Letters to the Reverend Mr John Kennedy, 1775; 10. A Third Letter to the Reverend Mr John Kennedy, 1775. Mr Ferguson also communicated several papers to the Royal Society, which were printed in their Transactions. In 1805, a valuable edition of his Lectures was published at Edinburgh by Dr, now Sir David, Brewster, in two volumes 8vo, with notes and an appendix, intended to adapt the whole to the actual state of science.

FERGUSON, *Robert*, a Scottish poet, who acquired a considerable share of celebrity at a very early period of life, was born at Edinburgh on the 5th of September 1750 or 1751. His father, whose name was William, paid court to the muses as well as the son; but he wisely relinquished the study of poetry for the more certain emoluments of trade and commerce, and was employed in different mercantile houses both in Edinburgh and in Aberdeen. He was an accountant in the Linen Hall when he died, but never acquired any thing like an independent fortune.

The subject of this notice was of a weak and delicate constitution during infancy, so much so, indeed, that small hopes were entertained of his ever reaching the years of manhood. Yet such were the care and attention of his parents, that he was able to attend an English school by the time he was six years of age, when his progress was considered as very extraordinary; and it proved no less rapid at the High School of Edinburgh, which he attended for four years, acquiring a competent knowledge of the Latin tongue with very little labour or exertion. He then went to the grammar school of Dundee, and in two years afterwards to the university of St Andrews, which his father preferred to Edinburgh, because a gentleman of the name of Ferguson had left two bursaries for the education of as many boys of the same name.

Ferguson's health was never at any time impaired by severe study; yet he kept alive at the university the opinion which had been entertained of him whilst at school, and he was decidedly the first mathematician of his own standing. He was patronized by Dr Wilkie, professor of natural philosophy, but better known as the author of the *Epigoniad*, who conceived an attachment for him, as much perhaps for his poetical as his mathematical talents. This kindness was repaid by Ferguson, on the death of Dr Wilkie, by a beautiful eclogue to his memory, written in the Scottish dialect. A little before he left the university, Ferguson had conceived the idea of writing a tragedy on the death of Sir William Wallace, for which he had collected materials; but as he subsequently met with a work on the same subject, he abandoned the design, after he had completed two acts. His own reason for so doing is thus expressed: "Whatever I publish shall be original, and this tragedy might be considered as a copy."

He returned to Edinburgh when he had finished his studies, without having fixed on any particular employment; for although he was destined for the church by his father, on the death of the latter he paid but little attention to the expostulations of his mother. He also declined to enter on the study of physic, assigning as a reason, that when he read the description of diseases, he believed that he felt the symptoms of them all in himself. He was, however, induced to attempt the study of the law, in which, as might have been expected, he made no proficiency. He seems, however, to have turned a wishful eye to some sinecure place, in order to obtain which he paid a visit to an uncle who resided at Aberdeen, a man of literature and opulence, hoping that, through his influence, he might be settled in a manner suited to his merit. But in this expectation he was completely disappointed; for although his uncle at first showed him every mark of attachment, his fondness decreased by degrees, and in six months he desired his nephew in an abrupt manner to leave his house, without attempting to procure for him any kind of living.

His necessities at this period were so great that he copied papers in the commissary clerk's office for so much per sheet, an employment which he soon left in disgust. His exuberant wit, equalled only by his good nature, thoughtlessness, and social propensities, made all who knew him receive him with affection; but his powers of song and talents for mimicry often led him into the company of the dissipated, whose example could not fail to do him essential injury, and who had neither the power nor the inclination to provide for him through life. The irregularities in which he was thus led to indulge often awakened in him the reproaches of conscience; and the conversation of a minister, who understood his manner of life, appears to have made a deep impression on his mind. His remorse indeed soon afterwards assumed the appearance of absolute despair. His sprightliness entirely forsook him; but he gradually recovered from this despondency, and his health was at length fully restored. Soon afterwards he cut his head so severely in consequence of a fall, that he became delirious from the loss of blood; and in this condition he remained for some months, till the want of sleep and perpetual talking put a period to his existence on the 16th of October 1774. He was buried in the Canongate churchyard. Over his grave a monument was erected by Robert Burns, who loved his genius, and naturally sympathized with failings akin to his own. Had Ferguson united prudence with his abilities, he would have no doubt risen to distinguished eminence in the literary world. His poems in the Scottish dialect have been universally admired by his countrymen; and when we reflect that they were composed in the intervals of dissipation, they must be considered as unequivocal evidences of his genius.

FERIA, in the Roman Catholic breviary, is applied to the several days of the week; thus Monday is the *feria secunda*, and Tuesday the *feria tertia*, though these days are not working days, but holidays. The occasion of this was, that the first Christians were accustomed to keep the Easter week holy, calling Sunday the *prima feria*, and so on; hence the term *feria* was given to the days of every week. But besides these, there were extraordinary *feriæ*, as the three last days of Passion-week, the two following Easter-day, and the second *feriæ* of Rogation.

FERIÆ, in Roman antiquity, holidays, or days upon which the people abstained from work. Proclamation was generally made by the herald, by command of the *Rex Sacrorum* or *Flamines*, that all should abstain from business; and whoever transgressed the order was severely fined.

The *feriæ* were of two kinds; public and private. The public *feriæ* were fourfold: first, *Stativæ*, which were kept as public feasts by the whole city upon certain immoveable days appointed by their calendar, as the *Compitalia*, *Carmentalia*, and *Lupercalia*; secondly, *Feriæ Conceptivæ*, which were moveable feasts, the days for the celebration of which were fixed by the magistrates or priests, as the *Feriæ Latinæ*, *Paganalia*, *Compitalia*, and others, which happened every year, though the days for observing them were left to the discretion of the magistrates or priests; thirdly, *Feriæ Imperativæ*, which were instituted by the mere command of consuls, prætors, or dictators, upon the gaining of some victory or other fortunate event; and, fourthly, *Nundinæ*. The *private* feriæ were holidays observed by particular persons or families, on several accounts, as birth-days, funerals, and the like. The *feriæ* belonged to and formed one division of the *dies festi*.

FERIÆ *Latinæ*, a festival at which a white bull was usually sacrificed. On this occasion the Latin and Roman towns provided each a quantity of meat, wine, and fruits; and during the celebration, the Romans and Latins swore eternal friendship to each other, taking home a piece of the victim to every town. The festival was instituted by Tarquinius Superbus, when, having overcome the Etruscans and made a league with the Latins, he proposed to build a common temple to Jupiter Latialis, at which both nations might meet and offer sacrifices for their common safety. At first the solemnity lasted but one day, but it was at different times extended to ten days. It was held on the Alban Mount, and celebrated with chariot races at the capitol, where the victor was treated with a large draught of wormwood drink.

FERIANA, the ancient city of Thala in Africa, which was taken and destroyed by Metellus in the war with Jugurtha. It was visited by Bruce in his travels through Africa, and he expected to find many magnificent ruins in the place, but was disappointed.

FERMANAGH, a county in the south-western part of the province of Ulster, in Ireland, is bounded on the north by the counties of Donegal and Tyrone, on the east by the county of Monaghan, on the south by the counties of Cavan and Leitrim, and on the west by those of Leitrim and Donegal. It extends over a surface of 471,348 acres, of which 320,999 are arable land, 101,952 are mountain and bog, and 48,797 are under water.

In the time of Ptolemy it was inhabited by the tribe of the Darini. Afterwards it came into the possession of the Maguires, the O'Flanagans, and the O'Reillys; the first-named of which families had the greatest share of property and influence, and its head was looked upon as the dynast or chieftain of the territory. On the settlement of Ulster in the commencement of the reign of James I. the English family of the Coles was ranked among the principal residents. The county was made shire-ground, along with the rest of Ulster, by Elizabeth, when it was divided into the eight baronies of which it consists at present, viz. Clonkelly, Coole, Glenawly, Knockninny, Lurg, Magheraboy, Maghera-Stephana, and Tyrkennedy. These baronies are subdivided into eighteen parishes and six parts of parishes, the remaining parts of which are included within some of the adjoining counties. According to the ecclesiastical arrangements of Ireland, the chief portion of this county is in the diocese of Clogher; three parishes only being in the adjoining diocese of Kilmore.

The surface is very uneven. The borders towards Tyrone and Cavan, on the east, are mountainous. The north-western portion towards Leitrim presents one continuous mass of hills, many of them high, rough, and boggy, amongst which Belmore Mountain, swelling out its massive sides towards Lough Erne, stands proudly conspicuous. From the summit of the Tossid Mountain is a most extensive prospect, commanding the view of several counties, and taking in the whole of the lake just mentioned. Quilca Mountain, partly in this county and partly in Cavan, rises to a very considerable height. The hills on the south-eastern side of the lough are disposed more in ridges than those near them in the adjoining county of Cavan.

The great feature of the county is Lough Erne, which divides it nearly throughout its whole extent from north-west to south-east. This fine sheet of water forms two long lakes, connected by a strait, on which the town of Enniskillen is situated. They are distinguished by the names of the Upper and Lower Lakes. The former, or the more inland, which lies between Belturbet and Enniskillen, is eleven miles in length, and from half a mile to six miles in width. The latter, which lies between Enniskillen and Belleek, is thirteen miles long, and from two to ten broad. The borders of both are finely broken by numerous bays and inlets, formed by the projections of the surrounding mountains and hills. Both parts of the lake are studded with numerous islands. Popular report makes the number of these equal to that of the days of the year; and, if all the detached points of rock or land visible above water were taken into the account, this number would not be above the truth. There are not, however, more than a hundred and fifty of them which deserve the name of islands. They are in general well formed for scenic effect, and many of them are planted, chiefly with ash and oak, even to the water's verge. Part of the Upper Lake is so much crowded with them as to give it the appearance, in some parts, more of a flooded country than of an extensive sheet of water. The islands in the Lower Lake are more numerous and picturesque. The largest is Bo or Cow Island, so called from being employed as pasturage; it is situated near the western extremity of the lake. But Devenish Island, near its eastern end, though smaller, is much more celebrated, from having on it one of the most perfect pillar towers in Ireland. Its height is eighty-two feet, and its circumference forty-nine. It is built of cut stone, and finished at the top with a conical roof. Near the summit of the hill which forms the island is the abbey of St Mary's, of which the belfry staircase and some of the Gothic pillars still remain. At the foot of the hill is a church dedicated to St Molush; and in its vicinity are the remains of that saint's house, roofed and finished with cut stone. Within a few paces of the house is a stone trough, about six feet long, said to have been his bed, in which those affected with various complaints perform certain prescribed ceremonies, in the hope of obtaining relief. In the island of Ennism'saint are the ruins of an abbey founded by St Nevnid, whose festival is annually celebrated in it. The saint's bell, ornamented with gold and silver, is still preserved in the island, and held in such veneration as to be used as a relic to swear upon. In the same island is a burying-ground, having a large stone cross at its entrance. Innismore is the largest island in the Upper Lake. Belle-isle, containing about two hundred acres, once the favourite residence of the Earl of Ross, and celebrated as well for its natural beauties as for the taste displayed in its improvements, has been suffered to fall into such decay that scarcely a vestige remains of what it once had been. It is connected with the main land by a bridge. Innisharkey Island, near the village of Crum, has been the residence of the representative of the Erne family since the destruction of Crum Castle. The navigation of the lake is chiefly carried on by small vessels called cotts, about ten feet long below, flat-bottomed, with upright sides, and sloping outwards at the stem and stern, so as to allow them to be brought close to the shallow margin of the lake. They are worked by oars; and a broad paddle at the stern serves instead of a rudder. This lake has been pointed out by a late celebrated engineer as an excellent station for steam navigation, although steamers cannot pass from it to Ballyshannon by the Erne, in consequence of the numerous cascades and rapids in that river. Neither is the harbour of Ballyshannon an advantageous site. The course of the steamers should be from Lough Erne through Lough Melvin, and by Manor Hamilton to Sligo; and thence to communicate with the head of the Shannon. Two other lines of inland navigation have been projected, commencing at Lough Erne, and terminating, the one eastwards at Lough Neagh, the other northwards at Lough Foyle; but nothing has as yet been effected towards the accomplishment of either of them. There are some smaller lakes in the county, the largest of which are Lough Melvin, on the borders of Leitrim, and Lough Macnean or Cane, on the confines of Cavan and Leitrim.

The only river of any importance is the Erne, which rises in the county of Cavan, and after passing through Belturbet, falls into Lough Erne at its south-eastern extremity; thence, passing by Enniskillen, it enters the Lower Lake, at the north-western extremity of which it again narrows into a river, and, passing through Belleek, forms a fine water-fall, bursting out through a thick wood in a broad sheet; and afterwards breaking over a ledge of shelving rocks, it foams through the arches of the bridge here thrown over it, after which it becomes more tranquil; yet, still maintaining a rapid current, during a course of nine miles, in which it crosses many lesser ridges of rock, it at length precipitates its water down a noble cataract into the Atlantic at Ballyshannon. The other remarkable rivers are, the Arney, the Ballenclarogh, the Ballycassidy, the Clodagh, the Kish Water, the Moorlaugh, and the Sillas; all of which, together with upwards of fifty smaller streams, contribute to the supply of Lough Erne.

The geological structure of the county consists of sandstone and secondary limestone, alternating with tolerable regularity. Red standstone exists in Tossid Mountain. Yellow sandstone, well adapted for building, lies round the town of Enniskillen. Limestone may be found in several of the islands in Lough Erne. A beautiful species of brown marble is found near Florence-court, a limestone district; but it requires to be worked to a greater depth than at present, in order to procure blocks and slabs free from flaws. Coal is said to have been raised in Glengarron Hills; but as no effort has lately been made to procure this mineral there, notwithstanding the avidity with which mines of every description have been sought out and purchased up, it may be inferred that it is not to be had in sufficient quantities to render it an article of general consumption. The cheapness of turf fuel, which is to be had in all parts, is another reason why coal is not more sought after.

Mineral springs are numerous. Rutty gives a list of nineteen, mostly sulphureous, but none are much frequented by strangers; the superior character of the waters of Swadlingbar, in the adjoining county of Cavan, having prevented any successful rivalry.

The population of this county has increased prodigiously from the period in which the subject became an object of special inquiry. According to the several authorities by which it has been ascertained, its progress is as follows:

1760, De Burgo	28,860
1792, Beaufort	71,800
1812, Parliamentary census	111,800
1821, Ditto	130,997
1831, Ditto	149,555

As far as these authorities can be relied on, it appears that the population has increased five-fold in little more than seventy years. At present it exhibits an average of one inhabitant to every three acres of land generally, and to every two cultivable acres.

The state of education, according to the returns made under the population act in 1821, and to those of the Board of Education in 1824–26, is as follows:

	Boys.	Girls.	Sex not ascertained.	Total.
1821	4032	2303	—	6335
1824–6	5685	3848	260	9793

Of the numbers in the latter return, 5283 were of the established church, 246 were Roman Catholics, and 4204 dissenters, whilst the religious persuasion of sixty was not ascertained. Eighteen schools, containing 1012 pupils, were supported by grants of public money; fifty-nine, containing 3433 pupils, by voluntary subscription; and the remaining 163 schools, containing 5348 pupils, were wholly maintained by the fees of the pupils. As far as the proportions between the religious persuasion of the pupils can be applied as a scale for estimating the adult population, the Catholic portion of it must be extremely small, not constituting more than one-fiftieth of the whole, the remaining forty-nine parts being divided in nearly equal proportions between the Protestants of the established church and the dissenters. But in deducing this inference, due allowance should be made for the circumstance, that the Catholic population chiefly prevails in the mountainous districts, in which the desire for education is more checked by local obstacles than in those parts nearer the towns and the general channels of communication.

Previously to the Union, the county was represented in the Irish parliament by four members, two of whom were returned for the county at large, and two for the borough of Enniskillen. At that period the number was reduced to three, one having been deducted from Enniskillen. No alteration has been produced by the reform act.

The state of the constituency at three periods, the first, before the disfranchisement of the forty-shilling freeholders, which took place on the passing of the Catholic relief bill; the second, subsequent to that event, but previously to the passing of the reform bill; and the third, exhibiting its present state, will appear from the following table:

	L.50.	L.20.	L.10.	40s.	Total.
1st Jan. 1829	252	183	...	6443	6878
1830	254	256	522	...	1032
1832	178	250	1001	...	1429

Of the last-named number of electors, 1015 voted at the first election under the reform act.

This county is almost exclusively agricultural. Farms vary from nine acres, chiefly under tillage, to large tracts for grazing. Much land is let in the gross to middle-men, who sublet it to smaller tenants. Landowners of this description are distinguished by the name of terny-begs, or little landlords. Tiernagh is the Irish word for a prince. There is much land belonging to the see of Clogher in the county. Rents are paid in the mountainous districts in young cattle, yarn, and butter. Oats and barley are the kinds of grain chiefly raised; wheat is comparatively little grown. The manures are, marl, limestone, limestone gravel, bog-mold, and bog-ashes. The marl is white and light, found under bogs and in banks. That about Florence-court is upon clay and gravel, with springs under it, which cause the marl to run into forms like cinders petrified, and of a reddish cast, as if from vitriolic acid. Marl is but little used in farming, limestone and gravel being found more productive. Land is generally prepared for potatoes by manuring it with dung, or with lime and bog-mud mixed, and with burnt clay, which is found to answer well. Some excellent pasture lands are grazed both by black cattle and sheep. A small breed of cows is to be met with in all parts. The general stock of sheep is of an inferior kind; neither is there any thing like a flock to be seen. Goats are common, in consequence of the ease with which they are maintained in the mountain pastures. Twenty of these are not counted as a *sum*, the term used in this county to signify the keep of a cow, or the quantity of land requisite to feed one. The hilly country affords coarse pasturage for large herds of young cattle; yet that it could be made still more productive by being brought under tillage, is evinced from the success which has attended every judicious effort of industry when thus directed. Timber is more general in Fermanagh than in some of the neighbouring counties. Beech grows to a large size. Ash is a tree peculiarly abundant, both here and in the adjoining counties of Cavan and Tyrone. In the first-mentioned of these counties, indeed, it is constantly found in the hedgerows; and, more particularly in the northern side of Lough Erne, it runs like a weed through the county.

The linen manufacture is carried on here to some extent. The principal kind made is what is termed seven-eighths. There are several bleachfields in different parts. A good deal of wool is also spun, which is generally worked up into druggets, the warp being of tow yarn and the weft of wool. It is chiefly consumed within the county. These manufactures, and the rearing of black cattle, may be considered as the main sources of wealth among the small farmers.

The fish chiefly taken in Lough Erne and its tributary streams are, pike, perch, white and speckled trout, bream, red roach, pullein, salmon, and eels both silver and mud, much esteemed for the excellence of their flavour. There are several large eel-weirs at Enniskillen, where great quantities of these fish are caught. They come from the sea when young, and are intercepted in their return. They never take the bait, nor are they known to take any kind of food. The country people catch them by extending across the stream a band of hay, in which they are so entangled that they are easily taken. Their average weight is about three pounds. Those not sold fresh or sent to Dublin are carried in barrels, each of which contains eight dozen, and are sold in Belturbet. Eighty dozen are sometimes caught in a night. There is also an eel-weir near the falls of Belleek.

Fermanagh has a few resident proprietors of high rank or large income. They are all members of the established church, and derive their titles to their estates from Elizabeth, James I., or Cromwell. A class of yeomanry is also to be met with, who distinguish themselves by the character of being "as good Protestants as any in Ireland;" a phrase implying not so much any superiority in religious qualifications, as a rooted aversion to their Roman Catholic neighbours. These are farmers, who hold tracts of land of considerable extent, and were settled in the county when the right to the elective franchise was exclusively in the hands of Protestants. At that period, Catholic tenants were often turned out of their farms, and sent farther up the mountains, to make room for the privileged class. The Protestants are a fine race of men, much superior in appearance to those of any other of the northern counties. This superiority arises, in all probability, from their habits of life, which, being peculiarly agricultural, with very little intermixture of sedentary employment at manufactures, are more favourable to the free expansion of the bodily powers. They are tall, well made, and robust. Their countenances display the bloom of health; and they enjoy that uninterrupted flow of animal spirits which is the constant attendant on regular living and active employment. Yet, whether from custom or natural propensity, the peasants do not rise early, and the cows are not milked till noon. There being but few markets for the produce of the soil, little encouragement is given to extraordinary exertion; they therefore seldom think of turning their time to the best advantage. The cottars are poor, and their cabins wretched huts, with a wattled door, and a mat on the inside. Yet many of the herdsmen who reside in the mountains are able to give their daughters on their marriage twenty guineas and a feather bed, although the cabins in which they reside are of the wretched description just mentioned, and seem to contain nothing but dirt and wretchedness. In cases of disease the lower classes have no confidence in medicine. When they send for the physician, they consider themselves as having signed their death warrant. An aversion is therefore entertained to the whole medical profession; and those who would not lay out sixpence in an apothecary's shop will hoard up considerable sums to provide for the expenses of a wake. The custom of assembling round the body of a deceased friend prevails universally amongst the Catholics of all ranks; but it is declining every year more and more amongst the Protestants.

The seats of the gentry are very splendid. The principal are, Castle Caldwell, a fine mansion at the foot of a large mountain, having in front the promontory of Rossagoul projecting into the lake, which is here studded with several fine islands; Florence-court, the seat of the Earl of Enniskillen, the façade of which, of the Ionic order, extends 260 feet; Belle-isle, already noticed; Castle Saunderson, near which are some druidical monuments; Dromcoo, Castlecoole, Castle Archdall, Brookborough, and Crum, where there is an extraordinary yew tree, which throws out branches to the distance of forty-five feet.

The towns in this county are few and small, none amounting in population to 6000 souls, and but two having more than 1000 souls each. Enniskillen, the county town, is situated on an island in the strait or river that connects the two portions of Lough Erne. As it was one of the great passes from Ulster into Connaught, it has always been considered as a place of importance. During the war of 1688 it was particularly celebrated for the stand it made against the forces of James II. At a very early period it was the seat of the chief of the Maguire family, the remains of whose castle still exist, having been converted into an artillery barrack. The town occupies the whole island, and is connected with the main land on both sides by a bridge at each end of the High Street. The parish church is a venerable structure, on an elevated position. There is also a Roman Catholic chapel, and three dissenting meeting-houses. The exterior of the county infirmary presents the appearance of a private gentleman's seat. The market-house is a light and graceful building, ornamented with a steeple, and containing a suite of rooms for balls and assemblies. The court-house is a plain, grave edifice. The other public buildings are the infantry barrack and the county jail, in the latter of which the prisoners, who are all clothed in a prison-uniform, and arranged in four classes, are employed in breaking stones. A school is kept in it; and the females are superintended by a matron. There is also a tread-mill. The average number of prisoners for the last few years has been seventy. At a small distance from the town is the public school founded by Charles I. who endowed it with an estate of 3360 acres. The head master receives a salary of L.500 per annum, with other advantages. The town maintains a good corn, butter, and flesh-market, which last is held in convenient shambles. The environs of the town are very beautiful. It opens on the view in a manner peculiarly fine from Florence-court. The hill above the town was formerly planted. A French engineer, sent over by Lord Pelham, cleared it of wood, and erected a fort on it, which, after it had been built, was discovered to be completely commanded by higher ground in the neighbourhood. Enniskillen is celebrated as a depôt for obtaining recruits for the army. A regiment of horse was raised here in the time of King William, which is still distinguished by the name of the Enniskillen dragoons. This circumstance, together with the general habits and character of the peasantry, has tended to keep up a military spirit throughout the county. There are few families which have not one or more sons in the army. Young men who intend to enlist travel from very distant parts to this town, where they are sure to meet with recruiting parties to receive them. The population of Enniskillen in 1821 was 2399; in 1831 it was returned at 5270. The only other town containing more than a thousand inhabitants is Irvinestown, formerly Lowtherstown, the population of which, according to the census of 1831, amounted to 1047. The other collections of houses are mere villages, nor are there many even of these.

FERMAT, Pierre de, equally celebrated as a restorer of ancient mathematics, and an original author of modern improvements, was born at Toulouse about 1595. His public life was occupied by the active duties attached to the situation of a counsellor of the parliament of Toulouse, in which he was distinguished both for legal knowledge and for strict integrity of conduct. Besides the sciences, which were the principal objects of his private studies, he was an accomplished scholar, an excellent linguist, and even a respectable poet.

His *Opera Mathematica* were published at Toulouse, in two volumes folio, 1670 and 1679; they are now become very scarce. The first contains the *Arithmetic of Diophantus*, illustrated by a commentary, and enlarged by a multitude of additional propositions. In the second we find a *Method or the Quadrature of Parabolas* of all kinds, and a *Treatise on Maxima and Minima, on Tangents, and on Centres of Gravity*; containing the same solutions of a variety of problems as were afterwards incorporated into the more extensive method of fluxions, by Newton and Leibnitz; and securing to their author, in common with Cavalleri, Roberval, Descartes, Wallis, Barrow, and Sluse, an ample share of the glory of having immediately prepared the way for the gigantic steps of those illustrious philosophers. The same volume contains also several other treatises on *Geometric Loci*, or *Spherical Tangencies*, and on the *Rectification of Curves*, besides a restoration of *Apollonius's Plane Loci*; together with the author's correspondence, addressed to Descartes, Pascal, Roberval, Huygens, and others.

It was too much Fermat's custom to leave his most important propositions wholly undemonstrated; sometimes, perhaps, because he may have obtained them rather by induction than by a connected train of reasoning; and, in other cases, for the purpose of proposing them as a trial of strength to his contemporaries. The deficiency, however, has in many instances been supplied by the elaborate investigations of Euler and Lagrange, who have thought it no degradation to their refined talents to go back a century in search of these elegant intricacies, which appeared to require further illustration. It happened not uncommonly, that the want of a more explicit statement of the grounds of his discoveries deprived Fermat, in the opinion of his rivals, of the credit justly due to him for accuracy and originality. It was thus that Descartes attempted to correct his method of *maxima* and *minima*, and could never be persuaded that Fermat's first propositions on the subject were unexceptionable. Fermat was however enabled to pursue his favourite studies with less interruption than Descartes; and the products of his labour were proportionate, as Lacroix remarks, to the opportunities he enjoyed, as well as to the talents he possessed.

There is a very ingenious proposition of Fermat, which deserves to be particularly noticed, on account of the discussion that it not long ago excited among mathematical philosophers. He has demonstrated that the true law of the refraction of light may be deduced from the principle, that it describes the path by which it can arrive in the shortest possible time from any one point of its tract or course to another; on the supposition, however, that the velocity of light is inversely proportional to the refractive density of the medium: and the same phenomena of refraction have been shown by Maupertuis to be deducible, upon the opposite supposition with respect to the velocities, from the law of the minimum of action, considering the action as the product of the space described into the velocity. But the law of Fermat is actually a step in the process of nature, according to the conditions of the system to which it belongs in its original form; whilst that of Maupertuis is at most only an interesting commentary on the operation of an accelerating force. It was Newton who showed the necessary connection between the action of such a force and the actual law of refraction; demonstrating that all the phenomena might be derived from the effect of a constant attraction, perpendicular to the surface of the medium: and, except in conjunction with such a force, the law of Maupertuis would even lead to a false result. For if we supposed a medium acting on a ray of light with two variable forces, one perpendicular to the surface, and the other parallel to it, we might easily combine them in such a manner as to obtain a constant velocity within the medium, but the refraction would be very different from that which is observed, though the law of Maupertuis would indicate no difference; so that the law must be here applied with the tacit condition that the refractive force is perpendicular to the surface. In Laplace's theory of extraordinary refraction, on the contrary, the tacit condition is, that the force must *not* be perpendicular to the surface; so that this theory not only requires the gratuitous assumption of a different velocity for every different obliquity, which is made an express postulate, but also the implicit admission of the existence of a force, determinate in direction and in magnitude, by which that velocity is modified, and without which the law of Maupertuis would cease to be applicable. It may indeed be said, that the supposition of a medium exhibiting unequal velocities, and attracting the light perpendicularly, is unnatural, and that the law is the more valuable for not being applicable to it; but a mathematical equation is true even with respect to impossible quantities, and a physical law, however useful it may be, requires physical proof; and it will not be asserted that the law of Maupertuis has been or can be established by physical evidence sufficiently extensive to render it universal.

Fermat died at Toulouse in the end of 1664, or beginning of 1665, at the age of seventy. He left a son, Samuel de Fermat, who was a man of some learning, and published translations of several Greek authors. (L. L.)

FERMENT, any body which, being applied to another, produces fermentation.

Ferments are either matters already in the act of fermentation, or those which soon pass into this state. Of the first kind are the flowers of wine, yeast, fermenting beer, or fermenting wine, and of the second are the newly-expressed vegetable juices of summer fruit.

Amongst distillers ferments are all those bodies which, when added to the liquor, only correct some fault in it, and, by removing some obstacle to fermentation, forward the process by secondary means; also such as, being added in time of fermentation, make the liquor yield a larger proportion of spirit, and give it a finer flavour.

FERMENTATION may be defined a sensible internal motion of the constituent particles of a fluid, mixed, or compound body; by the continuance of which motion these particles are gradually removed from their former situation or combination, and again, after some visible separation is made, combined together in a different order and arrangement, so that a new compound is formed, having qualities very sensibly differing from those of the original fluid. See BREWING and CHEMISTRY.

FERMO, one of the delegations of the papal dominions, in Italy, 580 square miles in extent. It contains one city, eleven market-towns, and thirty villages, with 77,089 inhabitants. It is situated on the shore of the Adriatic, and on that side is fruitful in wheat, maize, pease, beans, and fruit, and produces some silk. On the western side it consists of the Appennines, and is less fertile. The capital, of the same name, is about two miles from the shore, where is Porto Fermo, whence several fisheries are carried on. The city is surrounded with walls, and contains ten churches, besides the cathedral of the archbishop, eleven monasteries, and five nunneries. The inhabitants amounted in 1816 to 19,678, and are occupied in various trades. Long. 13. 36. 21. E. Lat. 43. 10. 18. N.

FERMOSELLE, a town of Spain, in the province of Leon, with an ancient castle adjoining it. The river Duero passes by it a little above the part at which the Tormes, that flows by Salamanca, joins that river. This town possesses a population of 3000 souls.

FERNANDO, or FERNANDES, an island in the Pacific Ocean. See JUAN FERNANDES.

FERNANDO DE NORONHA, or NARONHO, an island in the Atlantic Ocean, situated about 210 miles from the coast of Brazil. It is only about three miles in length, and is full of mountains, which, however, are clothed with verdure. It possesses a fort, which is garrisoned; but the island is of little use, except as a place of banishment for male criminals. Long. 32. 28. W. Lat. 3. 56. S.

FERNANDO PO, an African island, situated near the coast of Benin. It was discovered in 1471 by a Portuguese navigator, whose name it bears. It is about sixty miles in circumference, and is both fertile and beautiful, yielding abundance of rice, fruit, sugar canes, and tobacco. It is however little frequented by strangers; and the inhabitants, who are about 1200 in number, are said to be rude and uncivilized. Long. 8. 40. E. Lat. 3. 28. N.

FERNANDO SAN D'APURE, a town of South America, in the province of Caraccas. It is situated on the great river Apure, and is chiefly inhabited by shepherds; who pasture their flocks and herds upon the surrounding plains. The population has been estimated at about 6000.

FERNELIUS, JOHN, physician to Henry II. king of France, was born at Picardy towards the close of the fifteenth or beginning of the sixteenth century. Being sent to Paris to study rhetoric and philosophy, he applied himself so intensely that all other pleasures became insipid, and he cared neither for play, nor walking, nor entertainments, nor even conversation. He read Cicero, Plato, and Aristotle, and also applied himself earnestly to the mathematics. This continual study brought on an attack of sickness, which obliged him to leave Paris. On his recovery he returned, designing to study physic; but before he had an opportunity of applying himself to this pursuit he was employed to teach philosophy in the college of St Barbara. After this he spent four years in the study of physic; and having taken a doctor's degree, confined himself to his closet, in order to read the best authors, and to improve himself in the mathematics, as far as the business of his profession would permit. Never, in fact, was there a man more diligent than Fernel. He used to rise at four o'clock in the morning, and study till it was time either to read lectures or to visit his patients. But as attending patients did not occupy his whole time, he read public lectures upon Hippocrates and Galen, which soon gained him a great reputation throughout France and in foreign countries. When his business increased, however, he left off reading lectures, and spent all the hours he could spare in composing a work on physic, entitled *Physiologia*, which was soon afterwards published. But he was prevailed with to read lectures upon this new work, which he did for three years; and having published another work, *De Venæ Sectione*, he was under the necessity of reading lectures some years longer, in order to explain this new book to his pupils. Whilst thus employed, he was sent for to court, in order to try whether he could cure a lady whose recovery was despaired of; and being fortunate enough to succeed, this circumstance was the cause of the esteem which Henry II., then dauphin, and in love with that lady, conceived for him. This prince offered him the place of first physician; but Fernel, who preferred his studies to the bustle of a court, respectfully declined the employment. When Henry came to the throne, he renewed his entreaties; but Fernel represented that the honour offered him was due, as an hereditary right, to the late king's physician, and that, besides, he required time to make experiments concerning several matters relating to medicine. The king admitted the validity of this excuse; but as soon as the physician of Francis I. died, Fernel was called to occupy his place at the court of Henry II. And here the contrary of what he had apprehended came to pass; for he enjoyed more leisure at court than he had done at Paris; and he might have considered it as an agreeable retirement, had it not been for the journey which the new civil war obliged the king to undertake. Fernel died in 1558, leaving behind him many works besides those which have been mentioned. They have been printed several times, with his life prefixed, written by William Plantius, his disciple.

FERNEY, a town of France, in the department of the Ain, and arrondissement of Gex. It is situated on an elevated spot, not far from the lake of Geneva, and contains 750 inhabitants. It is only remarkable from the château there having been the residence of Voltaire from 1762 to 1777.

FEROKABAD, a town of Hindustan, on the coast of Malabar, which was taken by the British under Colonel Hartley, in 1790. It is ten miles south of Calicut.

FERONIA, the pagan goddess of woods and orchards. This deity took her name from the town of Feronia, situated at the foot of Mount Soracte in Italy, where a wood and temple were consecrated to her worship. Both are mentioned by Virgil in the catalogue of Turnus's forces. Strabo relates that those who sacrificed to this goddess walked barefoot upon burning coals, without being hurt. Feronia was the guardian deity of freed men, who received their cap of liberty at her temple.

FEROZEGUR, a town of Hindustan, belonging to the Nizam, in the province of Beeder, 120 miles south-west by south from Hyderabad. Long. 77. 22. E. Lat. 16. 8. N.

FEROZEPOOR, a town of Hindustan, in the Sikk territories, in the province of Lahore, fifty-two miles south by east from the city of Lahore. Long. 75. 58. E. Lat. 31. 5. N

FERRAH, a large walled town of Afghanistan, situated in a fertile valley, which was visited by Captain Christie. It gives name to a considerable river, which falls into the lake of Zarra, and is supposed to be the Parrah of ancient Parthia, a place of great splendour and extent. Long. 61. 40. E. Lat. 33. 7. N.

FERRAJO-Porto, a city, the capital of the Isle of Elba, in the Mediterranean. It is situated on a rocky projection into the sea, to which there is but one accessible passage from the land. It contains 3143 inhabitants; but since the departure of Bonaparte, is again become a mere place for the fishery. Long. 9. 55. E. Lat. 42. 49. N.

FERRARA, one of the delegations of the papal dominions in Italy, which extends over 1210 square miles. It contains two cities, thirteen market-towns, and 254 villages, with 170,727 inhabitants. The greater portion of the district is the delta formed by the mouths of the Po, and is very unhealthy; but it is fertile, and produces good crops of wheat, rice, maize, hemp, flax, oil, and silk. The breed of cattle is very good; the dairy is extensively followed, and produces excellent cheese. There are two fortified places, which are occupied by Austrian garrisons. The capital is a city of the same name, situated on a branch of the Po, one of the finest in Italy, with broad and regular streets; but the houses and magnificent palaces are nevertheless very thinly inhabited. It contains, besides the cathedral, 100 churches, twenty-two monasteries, sixteen nunneries, and 5100 houses, but only 23,100 inhabitants. The university has been destroyed. There is little or no trade, and no manufactures. The citadel is garrisoned by Austrian troops. Long. 11. 31. 5. E. Lat. 44. 49. 56. N.

FERRARS, George, was descended from an ancient family in Hertfordshire, and born about the year 1510, at a village near St Alban's. He was educated at Oxford, and thence removed to Lincoln's Inn, where, having applied with uncommon diligence to the study of the law, he soon became distinguished for his elocution at the bar. Cromwell, earl of Essex, the great minister of Henry VIII. introduced him to the king, who employed him as his menial servant, and in 1535 gave him a grant of the manor of Flamstead, in his native county. This is supposed to have been a profitable estate; but Mr Ferrars being a gay courtier, and probably an expensive man, about seven years afterwards he was taken on execution by a sheriff's officer, for a debt of two hundred merks, and lodged in the compter. Being at this time member for Plymouth, the House of Commons immediately interfered, and he soon obtained his liberty. He continued in favour with the king till the end of his reign; and in that of Edward VI. he attended the lord protector Somerset as a commissioner of the army, in his expedition to Scotland in 1548. In the same reign, the young king being then at Greenwich, Mr Ferrars was proclaimed Lord of Misrule, that is, prince of sports and pastimes; which office he discharged during twelve days, in Christmas holidays, to the entire satisfaction of the court. This is all that is known of Mr Ferrars, excepting that he died in 1579, at Flamstead in Hertfordshire, and was buried in the parish church. He was not less celebrated for his valour in the field than for his accomplishments as a gentleman and a scholar, and he wrote, 1. History of the Reign of Queen Mary, published in Grafton's Chronicle, 1569, fol.; and, 2. Six tragedies, or dramatic poems, published in a book called the *Mirror for Magistrates*, first printed in 1559, afterwards in 1587, and again in 1610.

FERREANAH, a town of Tunis, in Africa. It bears evident traces of great antiquity, and of having been formerly the largest city of this portion of the Tunisian territory. This, it is usually affirmed, is somewhat unaccountable, because, though the town enjoys a good climate, and is well supplied with water, yet the surrounding country is arid and barren in the highest degree. But the difficulty vanishes when we consider that it lies in the vicinity of a great desert of sand, which is perpetually shifting, and gradually overwhelming whole tracts of country, which were formerly covered with luxuriant vegetation. Such may have been the case with regard to the country surrounding Ferreanah. Dr Shaw conjectures that it is the site of the ancient Thala, which is so particularly described by Sallust in his narrative of the Jugurthan war. Ferreanah is about 130 miles south-west of Tunis.

FERRETTO, in glass-making, a substance which serves to colour glass.

FERRO, or Hiero, the most westerly of the Canary Islands, and, besides being the smallest, also the most arid and barren. It has a population of about 5000 souls, and a superficies of twenty square miles. The coast is rugged, and the soil contiguous to it is barren; but in the interior the face of the country improves, and there is a considerable portion of the island level and fruitful. The chief product is figs, which are produced in great quantities; and, to prevent their being lost, they are frequently used in making brandy. This spirit, together with wine, which is also made here, is exported to Teneriffe. Various aromatic flowers grow in great abundance; and bees thrive exceedingly well, yielding excellent honey. Ferro is but scantily supplied with water, there being only two or three fountains on the island; so that the cattle, which are numerous, are but ill provided with this indispensable commodity. Ferro was formerly supposed to be the most westerly point of the old world, and hence geographers drew their first meridian of longitude through it. This practice, however, has been abandoned; and almost every nation now makes the first meridian to pass through its own capital, not, we apprehend, with any advantage to science, but rather the reverse. Long. 17. 46. W. Lat. 27. 45. N.

FERRO, or FEROE ISLANDS. See FAROE.

FERROL, a city of Spain, in the province of Gallicia. It is one of the most important of the naval arsenals of the kingdom. Its harbour is deep, capacious, and secure; and the entrance so narrow that not more than one ship at a time can enter. From the mouth being so narrow, it is exposed to the inconvenience of not admitting the entrance or departure of vessels, but with a wind blowing from one particular point. The dock-yard is supplied with ship timber from the Asturias, and with hemp and flax from Aragon; and cordage and sail-cloth are manufactured in the royal workshops. The dry-docks for building and repairing ships in the suburb called Esteyro, are well constructed. At Neda, near the city, a building was lately erected, upon a large scale, for rolling copper into sheets for the bottoms of ships, and for preparing the other works required for coppering ships. The harbour, as well as the city, is very strongly fortified; but some heights are said so to command them as to render the defences of little importance. The population of the city and suburbs amount to about 20,000, most of whom are subsisted by the wages of the arsenal. Long. 7. 41. 14. W. Lat. 43. 29. 30. N.

FERRUGINOUS, any thing partaking of iron, or which contains particles of that metal.

FERTE-LA-MILON, a fortified city of the department of the Aisne, in France, situated on the river Ourcq, containing 480 houses and 2070 inhabitants. It was the birthplace of the celebrated dramatist Racine in 1639.

FERTE SOUS JOUARRE, a town of France, in the department of the Seine and Marne, situated at the junction of the Lesser Morin with the Marne. It contained a university, and has now 434 houses, and 3700 inhabitants. The neighbourhood is celebrated for its cheese.

FERULA, a little wooden pallet or slice, reputed the schoolmaster's sceptre, wherewith he chastises the boys by striking them on the palms of the hands. The word is Latin, and has also been used to denote the prelate's crosier and staff. It is supposed to be formed from the Latin *ferire*, to strike. Under the eastern empire the ferula was the emperor's sceptre, as is seen on different medals. It consists of a long stem or staff, having a flat square head. The use of the ferula is very ancient among the Greeks, who used to call their princes ναρθηκοφοροι, or ferula-bearers.

In the ancient eastern church, *ferula* or *narthex* signified a place separated from the church, in which the penitents or the catechumens of the second order, called *auscultantes*, ακροαματικοι, were kept, as not being allowed to enter the church; and as the persons therein were under penance or discipline, hence the name of the place. *Sub* ferula *erant ecclesiæ*.

FESCENNIA, a city of Etruria, near Falerii, supposed to have occupied the site of the modern Galese, and belonging originally to the Siceli, who were dispossessed by the Pelasgi. Dionysius (i. 21) states that some customs of this latter nation were still observed in his time (29 B. C.). It is chiefly remarkable as having given birth to a species of verse called by the Romans *Versus Fescennini*, and sometimes also *Saturnii*, in reference to the remote antiquity of its origin. As all specimens of this species of poetry have disappeared, we must rest satisfied with the account given of it by Horace. According to him, it was employed at the solemn festivals of their gods, sung in alternate verses by the performers, and was of a gay and cheerful character. The wit was of the rudest kind, and the satire was often so severe, that the laws of the Twelve Tables found it necessary to guard against its abuse. The irregular metre in which these songs, as well as all the poetical attempts of the early Romans, were written, received the name of Saturnian verse. (Hor. *Ep.* ii. 1. 139; Liv. vii. 2; Casaubon *De Sat. Græc. et Rom. Poes.* p. 178; Palmström *De Satir. Orig.* p. 63.)

FESCENNINE VERSES, *Versus Fescennini*, see the preceding article. The word, according to Macrobius, is formed from *fascinum*, a charm, because the people conceived such songs calculated to drive away witches, or prevent the effect of their witchcraft; but its more probable origin is from Fescenni, a city of Etruria, where these verses originated, as above explained.

FESTI DIES, in Roman antiquity, certain days in the year devoted to the honour of the gods. Numa, when he distributed the year into twelve months, divided the same into the *dies festi*, the *dies profesti*, and the *dies intercisi*. The *dies festi* were again divided into days of sacrifices, banquets, games, and feriæ. The *dies profesti* were those days allowed to men for the administration of their affairs, whether of a public or private nature; and they were divided into *fasti*, *comitiales*, &c. The *dies intercisi* were days common both to gods and men, some parts of which were allotted to the service of the one, and some to that of the other.

FESTINO, in *Logic*, the third mood of the second figure of the syllogism, the first proposition of which is an universal negative, the second a particular affirmative, and the third a particular negative; as in the following example:

FES No bad man can be happy;
TI Some rich men are bad men;
NO Therefore, Some rich men are not happy.

FESTOON, in *Architecture* and *Sculpture*, an ornament in the form of a garland of flowers, fruits, and leaves, intermixed or twisted together. Festoons are now chiefly used in friezes and other vacant places which require to be filled up and adorned, and are in imitation of the long clusters of flowers, which the ancients placed on the doors of their temples and houses, executed upon festival occasions.

FESTUS, POMPEIUS SEXTUS, a celebrated grammarian and philologist, who probably flourished towards the close of the fifth century of our era, and who was at all events posterior to Martial, whom he cites under the word *Vespæ*. Festus abridged the great work of Verrius Flaccus, a learned grammarian, *De Verborum Significatione*, omitting obsolete expressions, which were to be treated of in a separate work. This abridgment, which is still extant, is divided into twenty books, in which each word is alphabetically arranged and explained; and it has justly been regarded as one of the most valuable works respecting the Roman language and antiquities which have come down to our times. Indeed, of all the grammarians, Festus is the one who, in the opinion of Julius Scaliger, has rendered the greatest service to the Latin language. The abridgment of Paulus Diaconus is a complete mutilation of the work of Festus. The latter was printed for the first time at Milan, 1471, in small folio, and about the middle of the sixteenth century successively published by Aldus Manutius, Maffei, and, lastly, by the learned Augustin, with notes, Venice, 1560. The Venice edition, which contains the abbreviation of the work of Festus by Paulus Diaconus, and also fragments of Verrius, was reprinted at Paris, 1575, in 8vo, under the superintendence of Joseph Scaliger. About the same time, Fulvio Orsini published the *Fragments* of Festus, as Rallus and Pomponius Lætus had transmitted them to Politian and to J. B. Pius, Rome, 1581, in 8vo; and they were afterwards inserted by Denis Godefroi in the collection of the *Auctores Latinæ Linguæ*, published at Geneva, 1602, in 4to. Lastly, the excellent edition of Dacier, *in usum Delphini*, appeared at Paris in 1681, 4to, and was reprinted in the same form at Amsterdam in 1699, with the notes of Antony Augustin, Fulvio Orsini, and Joseph Scaliger.

FETLOCK, in the manège, a tuft of hair growing behind the pastern joint of many horses; but those of a low size have scarcely any such tuft.

FEUCHTWANG, a bailiwick of the circle of the Rezat, in the kingdom of Bavaria, extending over 115 square miles, and comprehending one city, one town, 101 villages, and 13,000 inhabitants. The chief place is the city of the same name, situated on the river Sulz. It has three churches, 226 houses, and 2150 inhabitants, who find occupation in making muslins, damask table-linen, hats, and leather.

FEUD, in our ancient customs, is used to signify a capital quarrel or enmity, not to be satisfied but with blood; and hence it is usually denominated *deadly feud*. *Feud*, called also *feida*, and *faida*, in the original German signifies *guerran* or war. Lambert writes it *feeth*, and says that it signifies *capitalis inimicitia*, or implacable hatred.

FEUDAL LAW is that system of Gothic jurisprudence which reached its full maturity during the middle ages, and which long continued to regulate the tenure of real property in the principal countries of Europe. The relations of lord and vassal have undergone very essential changes, the knight no longer holds his estate on the condition of military service, and most of the feudal incidents have been gradually superseded as unsuitable to the spirit of modern times; but this law has left many deep traces behind it, and is so closely interwoven with our national institutions, that it could not without great difficulty be entirely disentangled. Where the substance has almost totally vanished, the form is in some instances not very advantageously retained.

Of the word feudal many different etymologies have been proposed. According to Somner, who treads in the steps of Selden and Spelman, feud is a German compound, which consists of *feh*, *feo*, or *feoh*, signifying a salary, stipend, or wages, and of *hade*, *head*, or *hode*, signifying quality, kind, or nature; so that, in its primary acceptation, feudum, or land held in fee, was such as was held in *fee-hode*, by contraction *feud* or *feod*; that is, in a stipendary way, with the acknowledgment of a superior, and a condition of returning some service for it, on the withdrawing of which, the land was revertible to the superior.[1] Sir Martin Wright has remarked that "this etymon not only suggests the most probable account of the word, but gives us the clearest description of the thing itself."[2]

The origin of the feudal system is a question which has been long and much agitated, and different authors have arrived at very different conclusions. "It has puzzled the learned," says Dr Stuart, "to discover the nation of the barbarians which first gave a beginning to fiefs. No inquiry could be more frivolous. In all of them they must have appeared about the same period; and they prevailed in all of them in consequence of the similarity of their situation on their conquests, and in consequence of their being governed by the same customs. It is not therefore to the principle of imitation that their universality is to be ascribed."[3] But the most comprehensive and the most decided opinion is that of Mr Pinkerton, who avers that "the feudal system, about which so much noise is made, is the natural fruit of conquest, and is as old in the world as conquest. A territory is acquired, and the state, or the general, bestows it on the leaders and soldiers, on condition of military service, and of tokens acknowledging gratitude to the donors. It was known in the Greek heroic ages. It was known to Lycurgus, for all the lands of Sparta were held on military tenure. It was known to Romulus, when he regulated Rome. It was known to Augustus, when he gave lands to his veterans, on condition that their sons should, at fifteen years of age, do military service. The reason it did not preponderate and corrupt in Greece and Rome was, that it was stifled by the necessary effects of cities, as above mentioned. In Persia, where there were no cities of any power or privilege, it preponderated and corrupted at an early period. The feudal system, whether in its original democracy, or corrupted into aristocracy, must limit the power of kings; for men who hold their possessions on military service, must of course have arms in their hands: and even in absolute governments the soldiers are free, witness the prætorian bands and armies of imperial Rome, and the Turkish janisaries. By the feudal system every man held arms and freedom in his hands. Montesquieu has begun his account of the feudal system with that of the ancient Germans, given by Tacitus,[4] and prides himself in leaving off where others began. A writer more profound would leave off where Montesquieu begins."[5] This last sentence may be considered as a modest attempt at impressing the reader with an opinion that Pinkerton is a writer more profound than Montesquieu; but, without acquiescing in all his notions, we may at least admit that of the feudal system many authors have taken a view much too narrow and limited. The peculiar relation of lord and vassal, of territorial grants and the tenure of military service, is doubtless to be traced in very remote ages and countries. All the feudal incidents it may often be difficult to detect; but wherever we find portions of land granted to military vassals under the condition, express or implied, of following the standard of their lord, we there find the most essential characters of the feudal system. The order of chivalry may not be found completely engrafted: there may be no denomination equivalent to that of knight, and such incidents as those of relief, aids, and wardships, may be wanting; but instead of a faint analogy, there may still be a very close resemblance between one system and another.

[4] Montesquieu de l'Esprit des Lois, liv. xxx. chap. ii. seq.—Dr Stuart commences his researches from the same point. "In the manners of the ancient Germans," he remarks, "I have found the source and spirit of the feudal law." See likewise the elaborate work of Meyer, Esprit, Origine et Progrès des Institutions Judiciaires des principaux Pays de l'Europe, tom. i. p. 4. Haye, 1819-23. 6 tom. 8vo.

[5] Pinkerton's Dissertation on the Origin and Progress of the Scythians or Goths, p. 139. Lond. 1787, 8vo.

"It has been very common," says Mr Hallam, "to seek for the origin of feuds, or at least for analogies to them, in the history of various countries. But, though it is of great importance to trace the similarity of customs in different parts of the world, because it guides us to the discovery of general theorems as to human society, yet we should be on our guard against seeming analogies, which vanish away when they are closely observed. It is easy to find partial resemblances to the feudal system. The relation of patron and client in the Roman republic is not unlike that of lord and vassal, in respect of mutual fidelity; but it was not founded on the tenure of land nor military service. The veteran soldiers, and, in later times, some barbarian allies of the emperors, received lands upon condition of public defence; but they were bound not to an individual lord, but to the state. Such a resemblance to fiefs may be found in the zemindaries of Hindostan, and the timariots of Turkey. The clans of the Highlanders[1] and Irish followed their chieftan into the field; but their tie was that of imagined kindred and respect for birth, not the spontaneous compact of vassalage. Much less can we extend the name of feud, though it is sometimes strangely misapplied, to the polity of Poland and Russia.[2] All the Polish nobles were equal in rights, and independent of each other; all who were less than noble, were in servitude. No government can be more opposite to the long gradations and mutual duties of the feudal system."[3]

Macieiowski, a learned civilian of our own age, discovers manifest vestiges of the feudal system among the ancient inhabitants of Tuscany.[4] To the ancient relation of patron and client, the origin of feudal tenures was traced by Budæus, one of the first lawyers in modern times who applied a very ample store of classical erudition to the illustration of Roman jurisprudence.[5] The same opinion was adopted by Zasius, but it has deservedly been rejected by most of the subsequent commentators; nor is it easy to acquiesce in the speculation of Connanus, who deduces the principles of this law from the fraternities of Soldurii among the ancient Gauls.[6] The assignment of lands by the Roman emperors makes a nearer approach to the proper point. After Augustus had supplanted his rivals, he parcelled certain lands in Italy among his veteran soldiers; and to the classical reader it is well known that, upon this occasion, Virgil was deprived of his little patrimony. The example was followed by other emperors. Alexander Severus allotted to officers and soldiers various lands which had been acquired on the frontiers, and which were to descend to their heirs on the condition of performing military service. This was a plan for securing a permanent guard in the outposts of the empire; and, as Taurellus and Gothofredus have remarked, it bears some resemblance to the feudal system;[7] but Hotman has very clearly pointed out the distinction between these military retainers and the feudal vassals.[8]

Sir Thomas Craig has not overlooked the strong resemblance between the feudal tenures and the Turkish timars.[9] "The Spahyes," says Dr Thomas Smith, "are another great support of the Turkish empire; soldiers who are obliged to serve on horseback by the tenure of the lands (*timars*) and estates they are possest of; these being not only the reward of their sweat and blood, but ties and obligations to further service in the field upon the first summons; each bringing so many horses with him according to the value of what he holds, which is the reason they do not receive an asper of pay out of the Grand Signior's exchequer, and are therefore known by the name of Timar-Spahyes, or *Feudatory*, to distinguish then from other Spahyes who live in the cities, and have not obtained a piece of land."[10] A more recent author represents this military establishment as still unchanged. "These," says Dr Walsh, "are a kind of feudal cavalry, possessing hereditary lands, on the tenure of appearing in the field when called on. If they have no male children, the lands devolve to the commander, who assigns them to others on the same terms, and so the corps is kept up. It consists of sixteen legions; who are perhaps the best mountain horsemen in the world."[11] Major Denham discovered traces of the same system at Bornou in the interior of Africa. "The feudal law," as he informs us, "exists here in full force; and a man unwilling to serve, provides one or more substitutes, according to his means."[12] Here however we have but an inadequate representation of the feudal system. In the centre of India, this system is to be found in a more complicated and perfect form. Of its present character and condition in Rajasthan, some very curious and interesting details have been furnished by Lieut. Col. Tod, who supposes Asia to have been the cradle of feudalism. "The perfection of the system in England," he remarks, "is due to the Normans, who brought it from Scandinavia, whither it was probably conveyed by Odin and the Sacasenæ, or by anterior migrations, from Asia; which would coincide with Richardson's hypothesis, who contends that it was introduced from Tartary. Although speculative reasoning forms no part of my plan, yet when I observe analogy on the subject in the customs of the ancient German tribes, the Franks, or Gothic races, I shall venture to note them. Of one thing there is no doubt—knowledge must have accompanied the tide of migration from the east: and from higher Asia emerged the Asi, the Catti, and the Cimbric Lombard, who spread the system in Scandinavia, Friesland, and Italy."[1] Nor was this system confined to the continental part of Asia: Molina informs us that it prevailed to a great extent in the island of Japan.[2] That the germ of the feudal system first appeared in Asia, is at least highly probable. Its earliest traces have been discovered among the Gothic tribes of Europe. Successive swarms of Goths moved towards the north-western parts of the old world; and when they had subdued many different nations, it may be presumed that they settled the conquered provinces according to some general plan which they had learned in the east. Of the Asiatic tribes it is one great characteristic to adhere, from one century to another, to the customs of their ancestors. This remark is signally verified in the history of the Chinese and Hindus; and it seems applicable to all the other tribes of men who inhabit that quarter of the globe.

---

[1] "They are at present," says Dr Smollett, "as free and independent of their chiefs as the law can make them; but the original attachment still remains, and is founded on something prior to the feudal system, about which the writers of this age have made such a pother, as if it was a new discovery, like the Copernican system. Every peculiarity of policy, custom, and even temperament, is affectedly traced to this origin, as if the feudal constitution had not been common to almost all the nations of Europe. For my part, I expect to see the use of trunk-hose and buttered ale ascribed to the influence of the feudal system." (Miscellaneous Works, vol. vi. p. 275.)

[2] With respect to the state of vassalage in those two countries, consult Mr Coxe's Travels into Poland, Russia, Sweden, and Denmark, vol. i. p. 118. 137. vol. ii. p. 93. 110. Lond. 1784, 2 vols. 4to.

[7] Taurelli de Militiis ex casu, ad Ant. Augustinum Epistola, p. 83. Gothofredus ad Cod. Theodos. lib. vii. tit. xv. p. 305. "Quæ pleraque ad feudorum naturam proxime accedunt," says this most able commentator. Haloander supposes feuds to be mentioned in the Novels under the name of *militiæ*. "Animus erat in finem adjicere Feudorum Consuetudines, quas veteres appellare solebant jura militiarum, et Imp. nominat στρατιας." See his dedication prefixed to *Novellarum Constitutionum Dn. Justiniani Principis, quæ exstant, et ut exstant, Volumen.*" Norembergæ, 1531, fol. This opinion has however been refuted by different writers. "Militiæ enim," says Contius, "fuerunt officia certa ministris magistratuum assignata, quæ pecunia vendi poterant, et ideo in commercio erant, ut fuit officium apparitorum. Apparet ergo multum differre militiam a feudo. Nam militia est jus personæ; feudum in rebus immobilibus et quasi in possessione consistit." (Fornerii et Contii Tractatus de Feudis, p. 84. Leovardiæ, 1694, 8vo.)

Of the early progress of the feudal system, so able a delineation has been given by Dr Stuart, that we are here tempted to introduce a long extract from his work. Having quoted a passage from Tacitus,[3] he proceeds with the subsequent commentary. "This passage abounds in instruction the most important. It informs us that the German had no private property in land, and that it was his tribe which allowed him annually for his support a proportion of territory; that the property of the land was invested in the tribe, and that the lands dealt out to individuals returned to the public, after they had reaped the fruits of them; that, to be entitled to a partition of land from his nation was the distinction of a citizen; and that, in consequence of this partition, he became bound to attend to its defence, and to its glory. With these ideas, and with this practice, the Germans made conquests. In conformity therefore with their ancient manners, when a settlement was made in a province of the empire, the property of the land belonged to the victorious nation, and the brave laid claim to their possessions. A tract of ground was marked out for the sovereign; and, to the inferior orders of men, divisions corresponding to their importance were allotted. But while, in their original seats, such partitions were annual, it was expedient that they should now be invested in the possessor. A more enlarged idea of property had been gradually unfolding itself; and though it was convenient to, and suited the views of a narrow community, to take back its land, the measure was not practicable in an extensive society. Nations were no longer to shift their habitations. The boundaries of particular states were to be respected. The tribe ceasing to wander, the individual was also to be stationary. The lot or partition now received by him, was to continue in his possession, and to be an object of his industry. He was to take root, if I may so speak, in a particular spot. He was to bestow on it his affection; it was to feed and to enrich him with its produce. His family was to feel an interest in his estate; his sons were to succeed him. Heirs were to fail in the blood of the proprietor. It affected him, that the crown or a stranger should possess the subject of his toils and attentions. The powers of sale and donation came to be understood. The right of holding a landed territory with no limitation, and of disposing of it at pleasure, was known and prevailed.... When we mount up to the origin of customs, we are to be struck with their simplicity. The lot or partition to the sovereign was to constitute his domains. It was to support his splendour, to defray the expenses of government, and to maintain his household. The lot or partition to the individual was to give rise to allodiality. It was the land which was free, in contradistinction to tenure; and, being still the mark of a citizen, it subjected him as in Germany, to the general obligation of taking arms in defence of the community.[4] But the domains of the sovereign, and the lands of lot or partition to the people, could not exhaust all the territory of a conquest. They were principal and natural objects of attention; yet, after their appointment, there were much extensive property, and many fair possessions. The ancient maxims of the people did not allow them to seize these by a precarious occupation. Men who had connected the property of land with the tribe, and not with the individual, could not conceive any title in consequence of which they might arrogate possessions to humour their fancy, or to flatter their pride. Their ancient notions continued their operation: the community was concerned with what no man could claim. The lands accordingly which were assigned neither to the sovereign nor to the people, which formed not the domains of the former, nor the partitions of the latter, were the lands of the state or the fisc."[5]

[2] "Illud obiter dixerim, apud Japonenses nil videri esse frequentius quam feuda. Cum enim bellis perpetuo in ea ingenti insula principes inter se contendant, antiquo inter eos more, quæ unusquisque bello obtinet, continuo dividit inter suos duces, et alios quos diligit, cum onere sibi serviendi in bello, et alia onera præstandi; mutatque dominos de uno loco in alium, auferendo ab eis quæ possidebant, et alia eis largiendo. Majores autem dinastæ sub supremo aliquo principe ita constituti, divisa habent loca, quibus dominantur, in alios sibi inferiores, cum eisdem oneribus sibi inserviendi in bello et præstandi alia realia onera, et illi in alios, quousque devenitur ad infimos *tonos*, quos ipsi vocant, qui similiter dominantur unusquisque in suo oppido, et simili fere lege, ut vassalli ipsum comitentur in bellum, et servitia alia realia præstent. Mores tamen et usus feudorum non iidem, sed diversi in aliquibus sunt apud ipsos ab iis qui in Germania, Gallia, et Italia vigent." (Molina de Justitia et Jure, tom. ii. col. 1062. edit. Mogunt. 1659, 6 tom. fol.)

[3] Tacitus de Moribus Germanorum, cap. xxvi.

[4] "The allodial lands," as Dr Stuart remarks, "were enjoyed in full property, and are therefore opposed to feudal or beneficiary possessions, which were received with limitations, and under the burden of military service to the grantors." The word *al-od* is supposed to be equivalent to *all-hood*, and therefore to indicate completeness of possession. It is synonymous with *udal*, which is employed to denote the right of such lands in Orkney and Zetland; "whereby," as Lord Stair has stated, "without any infeftment, investiture, or other right or writ, they enjoy lands and hereditaments." (Institutions of the Law of Scotland, b. ii. tit. ii. § 11.) See likewise Lord Bankton's Institute of the Laws of Scotland, vol. i. p. 541. This word is evidently borrowed from the ancient Norwegian language. In the Islandic language, *ódal* signifies allodial property, but it also signifies *res derelicta*. (Haldorsonii Lexicon Islandicum, vol. ii. p. 121.) It is not therefore improbable that the term was originally applied to lands which, having been found deserted, were occupied without form or ceremony.

[5] Stuart's View of Society in Europe, p. 24.—It is not the object of this article to attempt a developement of the feudal system, but merely a faint outline of the history of the feudal law. Besides the different works which we here have occasion to quote, particularly those of Stuart and Hallam, we may refer the English reader to Dr Robertson's View of Society in Europe, prefixed to his History of Charles V.

Du Moulin has traced the origin of the feudal law to the Franks, by whom he supposes it to have been introduced into Gaul.[1] Grótius and other writers have, with greater probability, represented it as having been widely diffused at an early period.[2] Lombardy has frequently been regarded as the place of its origin, because to that country we are indebted for the ancient digest of this consuetudinary law.[3] The *Feudorum Consuetudines* are said to have been compiled by Gerardus Niger, who is likewise called Capagistus, and by Obertus de Orto or Horto, who were both lawyers and consuls of Milan.[4] They lived in the reign of Frederick the First, surnamed Barbarossa, which commenced in 1152, and terminated in 1190. Whatever share they might have in preparing the materials, it may perhaps be suspected that they did not digest the work in its present form. Their opinions are on some occasions placed in opposition to each other, and are quoted as if from distinct works. Thus in lib. ii. tit. li. § 3. "Similiter si quis investitus fuerit de feudo, ita ut ad fœminas transiret, et duas filias tantum reliquerit, quarum una filium habeat, et altera filiam; utrum post mortem illarum masculus tantum feudum habere debeat? Secundum Gerardum, masculus tantum: Obertus contra." And in § 6 of the same title: "Similiter feudum lege commissoria datum non valet, id est, si ad certum tempus pecunia non solvatur creditori, ut habeat in feudum. Gerardus. Et secundum Obertum, valet." On other occasions, both names are subjoined: "Gerardus et Obertus." It might indeed be conjectured that the work was arranged by their joint labour; and that when any difference of opinion occurred, they took care to state it in this formal manner. Du Moulin supposes Obertus to have been the sole compiler. We are assured by Odofredus, a commentator on the Code, who lived about the year 1250, that Hugolinus, otherwise called Hugo a Porta Ravennate, who died in the year 1168, added the feudal law to the ninth collation of the Novels, and that it was received as a tenth collation.[5] Some writers consider the statement as a mere device, intended to enhance the authority of this branch of jurisprudence. The feudal law is commonly subjoined to the *Corpus Juris Civilis*, of which many of the older civilians regarded it as a component part. "The last tome of the civile law," says Sir Thomas Ridley, "is the Feudes, that is, the books of customes and services that the subject or vassall doth to his prince or lord, for such lands or fees as he holdeth of him."[6] In the common editions, the *Feudorum Consuetudines* are divided into two books; but the edition of Cujacius, Coloniæ, 1588, 8vo, exhibits a new arrangement, with a series of five books. The first book he ascribes to Gerardus, the second and third to Obertus; the fourth is taken from several ancient authors, and the fifth consists of imperial constitutions relative to matters of feudal cognizance. To the common editions in two books, are likewise appended constitutions of several emperors; and two of them, issued by Henry the Seventh, are described by the term *Extravagantes;* a term which is also used in the canon law, to denote documents which wander beyond the limits of a particular collection.[7] The work itself is partly composed of such constitutions; and the entire collection closes with an instrument relative to the peace of Constance, *De Pace Constantiæ*, concluded, on the one part, between the emperor Frederick the First, his son Henry king of the Romans, and certain nobles of Germany, and, on the other, various cities of Lombardy, the march of Ancona, and Romagna.

These books of the feudal law are evidently written by individuals familiar with the doctrines and the phraseology of the civil law; and the new system of jurisprudence may be considered as a scion from the old. The composition necessarily partakes of the general barbarism of the age to which it belongs, nor are the materials reduced to a systematic or lucid form.[8] Some of the more classical civilians have therefore treated this law of Lombardy with the utmost contempt.[9] As to the authority which properly belongs to it, the feudalists have entered into much discussion, and have maintained various opinions. Some of the early writers represent it as having been sanctioned by different emperors, particularly by the first three Fredericks, but others consider this sanction as more than doubtful. Craig is induced to suppose that the feudal law must have derived its authority from some imperial rescripts, although they have not descended to our time; for he cannot conceive that the emperors would otherwise have permitted it to be taught in the schools, and observed in the judicatories. Du Moulin, on the other hand, considers the private part of the compilation as unwritten law, "jus non scriptum," adopted at Milan, and the remainder, the constitutions interspersed, as written law, "jus scriptum," retaining its force within the limits of the empire.[10] This appears to be a very sound opinion; nor do we think it necessary to mention the various suggestions and speculations of other writers. In many different countries, this compilation has been received and partly adopted as consuetudinary law, and in all those countries has been modified by tacit usage, or by express enactments, nor has it any other authority except such as it has thus obtained. The Lombardic body of law is described as "Feudorum Consuetudines," and "Jus Feudale commune;" the first title denoting that it is consuetudinary or unwritten law, and the second, that it has obtained more or less authority wherever the feudal law has been adopted.

The substance of these books was digested into a new form by Antonius Minuccius a Prato Veteri, a professor in the university of Bologna, who was born about the year 1380;[1] and his labours are said to have received the sanction of the emperor Sigismund, as they certainly did that of Frederick the Third.[2] Haloander had originally intended to subjoin it to his edition of the Novels; but it was not till after a long interval that the work was first published by Schilter. Another digest of the same materials was afterwards undertaken by Bartholomæus Baraterius or de Barateriis, who was a native of Piacenza, and was successively a professor at Pavia and Ferrara. Having completed his work in 1442, he dedicated it to the duke of Milan. It was first printed at Paris in the year 1612.[3] Neither of these works seems to have obtained any permanent footing, even in the universities of Italy. The books of the feudal law were exhibited in a German dress by Dr Lorenz Weidmann, who likewise introduced some changes of arrangement. His work, *Die Lehenrecht verdeutscht*, was printed by Schoiffer of Mainz in the year 1530.

The principles of the feudal law had soon begun to be taught in the universities. The text was illustrated by many glosses and commentaries; and many summaries and treatises have from time to time been added. The principal feudalists who preceded his own time, are thus enumerated by Dr Duck: "Horum librorum authoritatem augent egregii illi jurisconsulti qui ad eos glossas, commentarios, et tractatus scripserint. Glossas in Feuda scripserunt Bulgarus, Pyleus, Ugolinus, Vicentius, Jac. Goffredus, aliique; sed Jac. Columbinus eorum ultimus omnes superavit, et post eum, ait Jason, nemo glossas in Feuda scribere tentavit.[4] Alii summas et tractatus de Feudis composuerunt, Odofredus, Jac. de Arena, Hostiensis, Jac. Ardizoni, Zasius, Rebuffus, Hannetonius, Henr. Rosenthall, aliique, qui omnem Feudorum scientiam amplissime tradiderunt. Commentarios in Feuda scripserunt Jac. de Belvisio, Andr. de Iserma, Baldus, Jac. Alvarottus, Math. de Afflictis, Fr. Curtius, Jac. Cujacius, aliique, in quibus eminet Cujacii elegantia et literarum splendor, authoritas et judicium Jac. de Belvisio et Baldi, quorum ille octies se legisse libros Feudorum Papiæ testatur, Baldus vero commentarios suos scripsit postquam jus civile per quadraginta septem annos professus insignem famam acquisiverat. Et inter hos omnes e glossographis Jacobo Columbino, e summistis Jacobo Ardizoni, e commentariis Jacobo de Belvisio primus locus ab omnibus conceditur."[5] To this enumeration some names ought perhaps to have been added, particularly those of Hotman and Vulteius. Of the more recent commentaries on the text, the most copious is that of Caspar Bitsch, professor of law in the university of Strasburg.[6] Among the systematic treatises which have appeared since the publication of Duck's very useful work, it may be proper to mention the elder Struve's *Syntagma Juris Feudalis*, which contains much information in a form not very elegant or attractive.[7] Many elementary works, such as those of Schilter, Stryk, and G. L. Böhmer, and an immense number of detached dissertations, have from time to time been published in Germany, where every province of jurisprudence is most laboriously cultivated. Of separate tracts on the feudal law, an ample collection was published in Jenichen.[8] Various writers treat of this law as it has been adopted and modified in different countries. Thus the feudal law, as applied in Scotland, has been illustrated with much learning and ability by Sir Thomas Craig, one of the greatest lawyers whom his country has produced. One of the earliest books on the law of England is Thomas Littleton's treatise on tenures; and the feudal law of that country was afterwards discussed by Sir Henry Spelman, Sir Martin Wright, Sir Jeffrey Gilbert, and various other writers.

In France the feudal law was embodied in the *loi coutumier* of different provinces; and many curious reliques of jurisprudence have thus been preserved. The most interesting of these are perhaps the *Coustumes de Beauvoisis*, digested by Philippes de Beaumanoir.[9] Montesquieu has described it as an admirable work,[10] and has quoted it upon many different occasions. "This treatise of Beaumanoir," says Mr Barrington, "is so systematical and complete, and throws so much light upon our ancient common law, that it cannot be too much recommended to the perusal of the English antiquary, historian, or lawyer. He kept the courts of the Comte de Clermont, and gives an account of the customary laws of Beauvoisis (which is a district about forty miles to the northward of Paris) as they prevailed in the year 1283. He is consequently a more ancient writer than Littleton, and, to speak with all due reverence of this father of our law, perhaps a better writer. It need hardly be said that the customs of the two countries were at this time very similar, especially of the more northern parts of France: if we wanted other proof, the commentators on the oldest French law books cite Littleton as illustrating their customs."[1] Of the customary laws of France the other collections are very numerous.[2] Nor must we here neglect to particularize a very curious relique of early jurisprudence, the *Assises de Jerusalem*, which are decidedly of a French origin. After the conquest of the holy city in the year 1099, the barons who led the crusade elected Godefroy de Bouillon king of Jerusalem; and it was one of the new sovereign's first cares to form a body of laws for the government of his subjects. By the counsel of the patriarch, and of his princes and barons, "et des plus sages homes qu'il pooit avoir," he appointed wise men to make enquiry at persons from different countries as to the particular usages of those countries. Having received the desired information in writing, he again assembled his principal adherents; and having laid this document before them, and caused it to be read, he afterwards, with their counsel and concurrence, selected what to him seemed good, "et en fit assises et usages que l'on deust tenir et maintenir, et user au royaume de Jerusalem, par lesquels il, ses gens, et son peuble, et toutes autres manieres des gens alans, et venans, et demorans, fussent governés et menés à droit et à raison el dit royaume." They were called *Assises* from the circumstance of their having thus been confirmed in an assembly of the chief persons of the state. They were afterwards modified and enlarged by this king and his successors; and about the year 1250 were arranged by Jean d'Ibelin, Comte de Japhe et d'Ascalon, Seigneur de Rames et de Baruth. Having been adopted in the kingdom of Cyprus, they were revised in the year 1369 by sixteen individuals nominated in an assembly of the estates of that kingdom. They had been translated into Greek for the benefit of those subjects who did not understand the original language; and of this version some portions have been preserved in the Royal Library at Paris. After Cyprus had fallen under the dominion of the Venetians,[3] the book was translated into the Italian language.[4] It is generally admitted that the laws thus adopted in the kingdoms of Jerusalem and Cyprus, were in a great measure derived from the customs and usages of the kingdom of France.

Bourges, 1690, fol.—Of the *Assises de Jerusalem*, a new and complete edition, in three volumes quarto, was in 1830 announced by Cotta of Stuttgard. The editors are E. H. Kausler and J. C. Bluntschli, who promise a very careful revisal of the text, with copious and various illustrations; and, for the satisfaction of many readers, we may add that they write, not in German, but in Latin. Of the second part, the *Assise de la Court des Borgés*, the original has not yet been printed. Some extracts, relative to maritime law, may be found in Pardessus, *Collection de Lois Maritimes antérieures au XVIII*e *Siècle*, tom. i. p. 275. Paris, 1828, 4to.

[10] Montesquieu de l'Esprit des Lois, liv. xxvi. chap. xv.

The feudal system seems to have arrived at maturity during the reign and in the dominions of Charlemagne and his immediate successors. The reliques of their legislation are to be found in the *Capitularia Regum Francorum*, of which we have given a separate account. As the empire of Charlemagne not only included France and Germany, but likewise a great portion of Italy, and some portion of Spain, a certain uniformity of laws and usages was naturally promoted by this political union. "Feudal tenures," it is stated by Mr Hallam, "were so general in the kingdom of Aragon, that I reckon it among the monarchies which were founded upon that basis. Charlemagne's empire, it must be remembered, extended as far as the Ebro. But in Castille and Portugal they were very rare, and certainly could produce no political effect. Benefices for life were sometimes granted in the kingdoms of Denmark[5] and Bohemia. Neither of these, however, nor Sweden,[6] nor Hungary, comes under the description of countries influenced by the feudal system. That system, however, after all these limitations, was so extensively diffused, that it might produce confusion, as well as prolixity, to pursue the collateral branches of its history in all the countries where it prevailed."[7] The prevalence of the feudal law in Lombardy has already been mentioned; and it sooner or later extended its influence to almost every corner of Italy, including the islands as well as the continental states.[8] In England and Scotland it struck a very deep and vigorous root. Its progress in the former country seems to be correctly stated by Blackstone. "This feudal polity," he remarks, "which was thus by degrees established over all the continent of Europe, seems not to have been received in this part of our island, at least not universally, and as a part of the national constitution, till the reign of William the Norman. Not but that it is reasonable to believe, from abundant traces in our history and laws, that even in the times of the Saxons, who were a swarm from what Sir William Temple calls the same northern hive, something similar to this was in use; yet not so exclusively, nor attended with all the rigour that was afterwards imported by the Normans. For the Saxons were firmly settled in this island, at least as early as the year 600; and it was not till two centuries after, that feuds arrived to their full vigour and maturity, even on the continent of Europe."[9] Craig supposes the feudal law to have been established in Scotland before it was established in England;[10] but this is an opinion which apparently must continue to rest on conjecture, and not on historical evidence. (x.)

[8] The Sicilians, says Mr Brydone, "still boast that they retain more of the feudal government than any nation in Europe. The shadow indeed remains, but the substance is gone long ago." (Tour through Sicily and Malta, vol. ii. p. 225. Lond. 1773, 2 vols. 8vo.)

[9] Blackstone's Commentaries on the Laws of England, vol. ii. p. 48. See likewise Dr Sullivan's Historical Treatise on the Feudal Law, and the Constitution and Laws of England, p. 18. Lond. 1772, 4to.

[10] Cragii Jus Feudale, p. 47. Brussii Principia Juris Feudalis, p. 5. Edinb. 1713, 8vo. See Dr Stuart's Observations concerning the Public Law and the Constitutional History of Scotland, p. 7. Edinb. 1779, 8vo. Lord Kames, whose speculations often rest upon a very insecure foundation, is pleased to express himself in the following terms: "I entertain some doubts whether the feudal law was introduced into Scotland so early as in the reign of Malcolm II. What to me brought this thing first under suspicion, is a fact that can be made extremely evident. When one dives into the antiquities of Scotland and England, it will appear that we borrowed all our laws and customs from the English. No sooner is a statute enacted in England, but, upon the first opportunity, it is introduced into Scotland; so that our oldest statutes are mere copies of theirs. Let the Magna Charta be put into the hands of any Scotsman, without giving its history, and he will have no doubt that he is reading a collection of Scots statutes or regulations. Now it is a point settled among the best English antiquaries, that the feudal law was introduced into England by William the Conqueror. I need not spend time upon this topick, after what is said by the accurate Spelman, and by our countryman Craig. Joining these two things together, a strong presumption arises, that the feudal law made its progress from England to this country, as all the English statutes, making improvements and alterations upon it, certainly did. But this presumption receives additional force,

FEVERSHAM, a town of the county of Kent, in the hundred of that name, within the lathe of Scray, and forty-eight miles from London. It is a very ancient town, and from several of our early monarchs obtained various charters and privileges, especially as regards the judgment and punishment of offences committed within its own jurisdiction. Although it sends no members to parliament, it has, besides a mayor, jurats, and commoners, a steward, two recorders, and a chamberlain, and the corporation are trustees for various charitable institutions. Feversham is of comparatively less importance than formerly, as may be seen by its curious church, its town-hall, and some other buildings of great antiquity. It is now chiefly of consideration from the great manufactory of gunpowder carried on by the government, which gives occupation to many families; whilst others are employed in the fishery for oysters for the supply of London. Near to it the river Swale enters the sea, and the quarantine rendezvous of Sandgate Creek is so near as to form a communication with the ships under detention. There are good markets on Wednesdays and Saturdays. The great road from London to Canterbury avoids the town, though it passes within less than a mile of it. The population in 1801 amounted to 3488, in 1811 to 3872, in 1821 to 4208, and in 1831 to 4429.

FEVRE, Tannegui Le, in Latin *Tanaquillus Faber*, one of the most able scholars of his age, was born at Caen, in Normandy, in the year 1615. His father (who, according to Segrais, was the son of a grave-digger in the parish of St Jean de Caen), having dissipated his means, an uncle of the young Lefevre, a learned ecclesiastic, took charge of his education, and finding that he had a good ear and a fine voice, taught him music, by which means he was ere long in a condition to execute the most difficult pieces with the book open before him. He was twelve years of age when he commenced Latin, and his progress was extremely rapid. But the severity of his uncle discouraged him, and his father could only induce him to continue his studies by giving him another preceptor. The latter, however, did not understand Greek; but Lefevre learned it alone, without any other assistance than a grammar, and some books which he read before he was in a condition fully to comprehend their meaning. He was then sent to study humanity and philosophy at the college of La Flêche, one of the most celebrated which the Jesuits possessed in France. His masters made useless efforts to detain him amongst them; and his father and uncle equally failed in persuading him to take orders. After remaining several years in Normandy, he proceeded to Paris, where he soon made himself known, and gained the friendship of several persons of distinction. M. Desnoyers, one of these friends, presented him to Cardinal Richelieu, who appointed him inspector of the press of the Louvre, with a salary of two thousand livres. But, after the cardinal's death, the pension of Lefevre became ill paid, and he was even obliged to sell his library, in order to procure the means of subsistence. Some time afterwards, the Marquis of Francières carried Lefevre with him to Langres; but having in that city acquired a taste for the reformed doctrines, the latter took leave of his noble friend, and retired to Preuilly in Touraine, where he publicly made profession of Calvinism. He was immediately offered a chair in the academy of Saumur, which he accepted in preference to the professorship of Greek at Nimeguen, to which he was about the same time appointed. But he had afterwards some disputes with the consistory of Saumur, in consequence of having unguardedly attempted to excuse the libertinism of Sappho; and as the annoyance which this misunderstanding occasioned had determined him to quit Touraine, he was preparing to set out for Heidelberg, where the elector palatine had offered him considerable advantages, when he died of a fever produced by excess of labour, on the 12th of September 1672. By his marriage with Marie Olivier, Lefevre left three children; a son, named Tannegui after his father, who, after having for thirty years discharged the pastoral functions in Holland and in England, returned into the bosom of the Catholic church, and died at Saumur in 1717; and two daughters, one married to Paul Bauldry, and the other the celebrated Madame Dacier. Lefevre wrote better in Latin than in French; but if his productions are deficient in elegance, they have at least the merit of fidelity, and are accompanied with very learned notes. His productions consist of, 1. Editions of several works of Lucian, with a Latin version and notes; Longinus's *Treatise on the Sublime*, with the Latin and notes, Saumur, 1663; the Fables of Phædrus; Lucretius; the *Histories* of Ælian; Eutropius, Justin, Terence, and Horace; the *Library* of Apollodorus; Virgil; the *Panegyric of Trajan* by Pliny the younger; Dionysius of Alexandria, Anacreon, and Sappho: 2. French Translations of the *Festinus* of Xenophon, the *First Alcibiades* of Plato, the *Treatise on Superstition* by Plutarch, and the *Life of Aristippus* by Diogenes Laertius: 3. The translation into Latin verse of the *Fables* of Lockman, Saumur, 1673, in 12mo, a translation which was executed during his last illness: 4. *Diatribe Fl. Josephi de Jesu Christo testimonium suppositum esse*, Saumur, 1655, in 8vo; 5. *Epistolarum partes ii.* ibid. 1659, 1665, in two vols. 4to: 6. *Les Vies des Poètes Grees*, 1665, in 12mo, to which is subjoined *Le Mariage de Belfegor*, translated from the Italian of Machiavelli, and the Life of Theseus, translated from the Greek of Plutarch: 7. *Méthode pour commencer les Humanités Grecques et Latines*, in the *Mémoires de Littérature* of Sallengre, tom. ii. pt. 2, p. 62: 8. *Notes* on the *Scaligeriania Prima*. (See *Mémoires pour servir à la Vie de Tannegui Lefevre*, by Fr. Graverol, 1686; and the *Mémoires de Nicéron*.)

FEZ, an extensive country of Africa, and at one time the most flourishing kingdom in the northern part of that continent. It now, however, forms one of the four provinces or kingdoms into which the empire of Morocco is divided. It is bounded on the north by the Straits of Gibraltar and the Mediterranean Sea, on the east by Algiers, on the south by Morocco, and on the west by the Atlantic Ocean. Besides being bordered in one part by the chain of the Greater Atlas, a smaller one called the Lesser Atlas runs across it, extending from the Great Atlas to the sea near Tetuan, a considerable city situated on the Straits of Gibraltar. It is likewise traversed in various directions by other ranges of mountains, some of which are lofty, rugged, and barren, whilst others are adapted for pasture. The intervening plains and valleys, however, which are frequently many miles in extent, being finely watered, are in the highest degree fertile, and capable of producing all the luxuries of the eastern and western worlds. The soil of the interior is a rich black loam, which, although but very slightly cultivated, is remarkably prolific. The mountainous parts also might, by suitable cultivation, be made to produce abundantly those fruits which thrive best in the hilly regions of warm climates; but they are for the most part utterly neglected. The Moors know little of agriculture; and, besides, they only cultivate in proportion to their im-

---

when it is considered, that if we had the feudal law before it came into England, it must have been taken from some other people than the Normans, with whom we had no commerce." (Essays upon several Subjects concerning British Antiquities, p. 4. Edinb. 1747, 8vo.) Of such random assertions as these, it would be superfluous to attempt a formal refutation.

mediate wants; so that a considerable portion of the country is allowed to lie untilled. The principal rivers are the Mulluwia or Mulvia, which separates Fez from Algiers; the Morbeya or Ommirabee, which separates Fez from the province of Tedla; and the Seboo, which waters the interior of the country. Fez is estimated to contain about 89,000 square miles in superficial extent, and its territorial divisions are as follows:

Districts.	Chief Towns.
Erreef or El Rif.	
El Gharb.	Tetuan, Tangier, Arzilla.
Beni Hassan.	Sallee, Rabat.
Temsena.	Dar el Beyda.
Shawiya or Shavoya.	
District of Fez or Fas.	Fez, Mekennes.
Tedla.	

The government, statistics, and commerce of this region in every respect resemble those of Morocco, of which it is indeed a part, and they will accordingly be described under that article.

FEZ, or FAS, the capital of the above kingdom, was built in 786, by a prince of the name of Edris, and having soon risen to be a city of the first magnitude, became the capital of the western Mahommedan states. In the twelfth century it is said to have contained seven hundred temples and mosques, a number of which were erected upon a magnificent scale, and adorned with a profusion of marble pillars. It was at one time held in the highest veneration; and when the road to Mecca was shut up, in the fourth century of the Hegira, pilgrimages to Fez were performed by the western Moslemins, who considered it as a place nearly equally sacred with that where the Prophet had been born. It was also distinguished for its learning, at a time when the Saracens may be said to have enjoyed a monopoly of all the knowledge which then existed. Its schools of philosophy, physic, and astronomy, were famous throughout the Mahommedan kingdoms of Spain and Africa, and were not only resorted to by the youth of these countries, but likewise by Christians. When the Moors were driven out of Spain, Fez became the resort of numerous refugees, who, being superior in knowledge and civilization to their original countrymen, introduced several of the arts, the practice of which for a time retrieved the decaying fortunes of the city. But it gradually sunk with the declension of arts and wealth in Northern Africa; and when the kingdom of which it was the capital became incorporated with the empire of Morocco, it ceased to possess almost any political importance.

Fez is situated upon the slope of several hills, which surround it on every side except the north and north-east. As the town is built on inclined planes, and the ground is unpaved, the streets are very dirty, especially in rainy weather. They are, besides, so narrow, that two horsemen cannot ride together abreast in them; and the gloom thus produced is deepened by the houses (which are very high) having a projection on the first floor. The light is also intercepted by a sort of galleries or passages which connect the upper parts of the houses, and by the high walls which are raised at certain distances from one side of the street to the other, as if to support the buildings. These walls have arched passages, which are shut at night, and all communication between one part of the city and another is by this means cut off. The houses have a mean and ruinous appearance; they are either altogether destitute of windows, or possess but a few which are seldom larger than a common sheet of paper, and being placed very high, are generally covered with blinds. Behind the high walls there are some buildings which in the inside present something like comfort; but it is the general taste of the country to have a mansion composed of a court-yard, surrounded with a colonnade, which forms a kind of gallery both above and below. By these galleries the adjoining rooms are reached, and these commonly receive their light only from the door, which, on this account, is necessarily large. The rooms are long and narrow; the ceiling, composed of planks, is lofty, and sometimes ornamented; and the floors are paved with bricks, Dutch tiles, or marble, according to the wealth of the occupant. The roofs are covered with stamped earth, about one foot thick; and this singular casing, on account of its weight, bulges the walls outwards, and rends them into fissures, whilst it does not protect the houses from rain.

Fez properly consists of two distinct towns, *Fas el Bâlee*, or Old Fez, and *Fas el Jedid*, or New Fez. The latter, which was founded in the thirteenth century, stands on an eminence commanding the old city, and is surrounded with gardens, which abound in all sorts of delicious fruits and odoriferous flowers. This portion of Fez is principally inhabited by Jews. At the bottom of the valley, which is formed by the surrounding hills into a sort of funnel, runs the river *Wed el Juhor*, the river of pearls, so called on account of its value. Besides refreshing vegetation as it passes along, and plentifully supplying the city with water, it is made to turn several water-mills. Fez possesses a vast number of mosques, the finest of which is called *El Caroubin*. It was built during the flourishing period of the city, and is described by Leo Africanus as being a mile and a half in circumference. It is constructed of bricks, stones, and lime, but the architecture is said to be mean. It possesses, however, a great number of gates and arches, and two handsome fountains in the court. There are two other celebrated mosques, one of which (namely, that dedicated to Edris, the founder of the city), is the most frequented in Fez. The palace of the sultan is composed of a great number of court-yards, which serve as entrances to apartments. These consist, besides those for domestic uses, of rooms in which the business of government is transacted. The palace is situated upon an elevation in New Fez. None of the other buildings are in any respect remarkable. There are a great number of shops, to which the inhabitants of the surrounding country daily resort as to a fair, for the purchase of commodities, as they have neither shops nor working-places amongst themselves. Provision-markets are numerous, and the city contains about two hundred caravanserais or inns. The various trades, and the different articles sold, are divided into classes in separate streets, so that a whole street is occupied by those pursuing one species of traffic or art. Fez contains a vast number of public baths, some of which are good, and consist of several rooms heated to different degrees of temperature. There is an hospital richly endowed, but it is occupied solely by lunatics. There are also a great number of schools, the most distinguished of which are established at the mosques of Caroubin and of Muley Edris, in a small house or mosque called *Emdarsa* or academy. In these philosophy is taught, but of course very imperfectly.

The manufactures of Fez consist of woollen hhaïks, sashes, and silk handkerchiefs, slippers of good leather, which they tan remarkably well, red felt caps, some coarse linen cloth, fine carpets, a curious kind of earthenware, weapons of several kinds, saddlers' ware, and copper utensils. There are a few goldsmiths; but the adorning of the person with gold and silver being considered as a sin, this branch of industry is not much patronized. The arts here find little encouragement, and are indeed far inferior to those of Europe, except in the preparation of leather, and in the fabrication of carpets and of hhaiks, which the manufacturers know how to weave as fine and as transparent as gauze. They are also expert in wax-works, weapons, and harness. The heat during the summer is very great; but in other seasons of the year, particularly winter, the climate is agreeable. With regard to the number of inhabitants, much difference of opinion prevails amongst travellers. Mr Jackson estimates the population of the old and new city at 380,000 souls, which is certainly an exaggeration; whilst other authorities reduce the number as low as 60,000 and even 30,000 individuals, which is probably below the mark. The traveller who assumed the fictitious name of Ali Bey was told, whilst he remained there, that Fez contained 100,000 souls, and that before the last plague the inhabitants were double that number. Of this population about 2000 are Jews, who live in the most abject state, on account of the sovereign contempt with which they are treated by the Moors. They are almost all either artisans or merchants, and they have several synagogues, and a market-place, which is well provided. According to Ali Bey, the city is situated in long. 4. 58. 15. W. lat. 34. 6. 3. N. It is 160 miles south of Gibraltar, and 200 north-north-east of Morocco.

FEZZAN, a country of considerable extent in Northern Africa, and situated to the south of Barbary. Its northern boundary is the well of Bonjem, which is situated in lat. 30. 35. 32. N. South of this point it extends, according to Captain Lyon, six degrees and a half of latitude, or about 450 miles, and is bounded in that quarter by what are called the Wells of Meshroo. To the south and south-east is the country of the Tibboos, to the south-west that of the nomadic Tuaricks, and to the north-west the borderers are Arabs. Of this tract of country it is calculated that about 300 miles, stretching from north to south, are cultivated. The greatest breadth is estimated at 200 miles; but the Black Haratch to the east, and other deserts to the south and west, are, according to Horneman, included in its territory. Fezzan may be said to consist of a chain of verdant islands embosomed in an ocean of sand. Fine yellow sand, and a species of gravel, cover the whole surface of the plains, except where the Soudah and Haratch extend. It is only in the immediate neighbourhood of towns that the palm is cultivated, and that corn and esculent plants, of which a little is raised with great difficulty and labour, are produced. The plains of the desert consist of red sand and sand-stone, containing gypsum and rock-salt, associated with beds of dolomite and carbonate of lime. Soda, alum, saltpetre, and sulphur, are also found in this country.

In order to convey as clear and intelligible a view of Fezzan as possible, we shall follow the route generally pursued by travellers in proceeding from Tripoli to Mourzouk, the capital, and thence to the other parts of the country which have been described. About half a mile beyond the walls of Bonjem, which is the northern frontier, stands a Roman castle, situated amongst some high sand hills. It is of an oblong form, having in the centre of each of the walls a large arched gateway, between two strong towers. After leaving this interesting ruin, the traveller proceeds over a barren desert called Klia, the soil of which, where clear of sand, consists of gypsum intermixed with numerous shells. Twenty-two miles from Bonjem the road leads through a defile called Hormut Emhalla, or the Pass of the Army. After crossing a range of table-mountains called Elood, running north-east and south-west, it passes through a stony and very uneven plain, encircled with mountains, to the pass of Hormut Tazzet, which appears to be situated about sixty miles from Bonjem. After clearing this pass, the road opens upon a plain called El Grarat Arab Hoon. The journey now becomes harassing, on account of the scarcity of vegetation and water, and the frequency of sand-winds. The first place of importance that is met with on this route is Sockna, near which are a plantation of palms and two wells of fresh water.

Sockna, which is about half way between Tripoli and Mourzouk, is situated on an immense plain of gravel. It is bounded to the south by the Soudah Mountains, at the distance of about fifteen miles; to the eastward by the mountains of Wadan, at the distance of about thirty miles; to the westward by a distant range of hills; and to the northward by the country above described. The town, which is about a mile in circumference, is walled, and contains, according to Major Denham, considerably more than 3000 persons. The streets are very narrow, and the houses are built of mud mixed with small stones. The water is almost all brackish or bitter. In the immediate neighbourhood there are several hundred thousand date trees, which pay duty to the government. Sockna pays of duty annually about 2000 dollars, exclusively of a tax of one dollar on every 200 date trees. The Tripoli money is the currency of Sockna; and this occasions a considerable loss to the traders, who are obliged to pay their taxes in Spanish dollars, which they purchase at exorbitant prices. The dates grow in a belt of sand, at the distance of two or three miles from the towns; and their quality is far superior to any produced in the north of Africa, in consequence of which they bring a very high price in Tripoli. In the gardens situated about three miles from Sockna, barley, maize, a small quantity of onions, and a few other garden-stuffs, are cultivated. But there is little or no other kind of vegetation, so that all the animals are fed on dates. This place is infested with an immense quantity of flies, attracted probably by the dates, which are preserved in storehouses. The men have in general a clean and neat appearance, whilst the women are pretty and handsome, but remarkable, it seems, for their love of intrigue. The latitude of Sockna is 29. 5. 36. N.

Ten miles east by south from Sockna stands the town of Hoon. It is smaller than the former, but is built and walled in the same manner. Palm groves and gardens approach close to the walls of the town, and completely conceal it. The soil is sand, but it is fertilized and refreshed by little streams from wells of brackish water. Twelve miles east by north of Hoon stands the town of Wadan. Its external aspect is pleasing, being built upon a conical hill, on the top of which are some enclosed houses called the castle; but internally it is inferior to the two other towns in point of neatness, comfort, and convenience. There is here a well of great depth, cut through the solid rock. The bulk of the inhabitants of Wadan are *schereefs*, that is, pretended descendants of the Prophet, and Arabs who act as shepherds. A few miles eastward of the town there is a chain of mountains, which, with the town itself, derives its name from a species of buffalo called *wadan*, which is found here in immense numbers. There is also a great abundance of ostriches amongst these mountains, by hunting which many of the natives obtain a subsistence. At all the three towns, Sockna, Hoon, and Wadan, it is the practice to keep tame ostriches in a stable, and in two years to take three cuttings of the feathers.

The whole way to Mourzouk is now an almost uninterrupted succession of stony plains and gloomy wadys, with no water but that of wells, generally muddy, brackish, or bitter, and placed at widely extended intervals. Sand winds also prevail, and their visitations are at all times harassing, and not unfrequently destructive. Several towns or villages are situated in this long and dreary waste, and they are usually encircled with groves of palm. Sebha, which stands in latitude 27. 3. 8. N., is a mud-walled town, picturesquely situated on a rising ground, and surrounded by a palm grove. Two marches farther on lies Ghroodwa, a small and miserable collection of mud huts. The palms here, which are the property of the sultan, extend from ten to fifteen miles east and west. The leading features of the above remarkable tract of country may be shortly described. The basaltic chain known by the name of the Soudah, or Jebel Assoud, that is, Black Mountains, commences near Sockna, and extends from north to south three days' journey, but in so tortuous a direction as not, according to Major Denham, to exceed thirty-five miles in a straight line. Captain Lyon, however, is of opinion that they stretch nearly a hundred miles from north to south between the parallels of 28. 40. and 27. 30. To the westward they extend as far as the well of Assela, on the road to Shiati, a district to the westward of Sebha, where the red clay hills continue unbroken, and unite with those of Benioleed in Tripoli. To the east they extend three days to a wady called Temelleen, which lies on the way to Zella or Zala near Barca. They form, indeed, a branch or continuation of the mountainous desert called Haratch el Assouat, which was traversed by Horneman in his route from Cairo to Mourzouk. That traveller gives a fearful description of this wild region, so much dreaded by those who have had to traverse it. The mountain presents the appearance of an imperfect cone, and the rock, upon fracture, seemed to Horneman to consist of ferruginous basalt. Range upon range of black and dreary mountains, intersected by narrow and dismal ravines rather than valleys, rose before his view. Here and there, however, the eye was relieved by the sight of patches of vegetation, approaching even to luxuriance, from the rains which fall in this hilly region. Contiguous to the Black lies the White Haratch, a chain of mountains composed of friable limestone, and abounding in petrifactions. To the south of Sockna, the description of the Jebel Assoud, as given by Major Denham, exactly corresponds to that of the Black Haratch. Dr Oudney describes the hills as from 400 to 600 feet in height, the tops being in general tabular, but a few are irregular, and two or three terminate in conical peaks. The sides of all of them are covered with a considerable quantity of debris. Captain Lyon says the chain rises to an elevation of 1500 feet. The lower stratum of these hills is limestone mixed with a reddish clay, superimposed upon which are large masses of tabular basalt and irregular precipices, so common to this formation; whilst the sides occasionally present the usual steplike appearance, and in many instances are overhung by pillars, curved, inclined, and perpendicular. The whole exhibits a scene of barrenness which, according to Major Denham, cannot be perfectly described, either by poet or painter. After these dreary wastes have been passed, the hills of Zeghren commence. They run nearly east and west, are low, long, oval, and truncated at the top, and altogether different from any others which Denham and Oudney had seen. The town of Zeghren, according to the former traveller, is better built than any other in Fezzan.

Mourzouk, the capital of Fezzan, which stands in latitude 25. 54. N. and longitude 15. 52. E., is a walled town, containing about 2500 inhabitants, who are blacks, and who do not, like the Arabs, change their residence. The walls are built of mud, but sufficiently thick and high to guard the place from attack. As a substitute for stones, which are not to be found, the people use baked clay, a substance which is found sufficiently durable, as rain is here unknown. The houses are generally of one story; the doors are low and without hinges, but made to move upon a pivot. The streets are small and narrow, but there are numerous open spaces, destitute of buildings, and covered with sand, on which the camels of the traders remain. Many palms grow in the town, and a few red peppers and onions are cultivated. The street of entrance is a place about a hundred yards broad, leading to the walls which surround the castle, and is extremely elegant. The castle itself is an immense mud edifice, about ninety feet in height, and furnished with small battlements immensely broad at the base, but gradually tapering to about four feet in thickness at the top. Like all the rest of the buildings, the castle has no pretensions to regularity. It is the residence of the sultan, whose apartments are of the best quality, although, on account of the enormous mass of wall, all the rooms are of very small dimensions. The more spacious houses in Mourzouk are constructed in the manner which we shall now endeavour to describe. A large door, sufficiently high to admit a camel, opens into a broad passage, in which there is a stable, and near it a room for slaves. Opposite the stable is a large square apartment, the roof of which is supported by palm trees. In the centre of the roof is an open space, through which the apartment is lighted, for all the houses are destitute of windows. There is generally a divan or seat of mud about eighteen inches high and twelve feet long. From the sides of the large room, doors open into the smaller ones, and a passage leads into a yard which has small houses attached to it, and a well. There are sixteen mosques in Mourzouk, which are covered in, but some of these are very small. The principal one is a low building, destitute of elegance. The burying places are outside the walls, and of considerable extent. Owing to the want of wood, no coffins are used; the bodies are merely wrapped in a mat or linen cloth, and covered with palm branches, over which the earth is thrown. The men of the lower orders of Mourzouk wear a large shirt of white or blue cotton, with long loose sleeves, trousers of the same, and sandals of camel's hide; but the shirt being in general long, many have no other covering. Those of the better sort, however, attire themselves more gaily; and their dress nearly resembles that of the people of Tripoli. The men have little beard, which they likewise keep closely clipped. The dress of the women here differs materially from that generally worn by Moorish females, and their appearance is by no means prepossessing. They plait their hair in thick bobbins, which hang over the forehead, and anoint it so profusely with oil, that this liquid drips down over the face and clothes. From the back hair, however, ornaments of silver or coral are suspended. Other parts of the face and head, such as the ears, are profusely adorned. A woollen handkerchief is fastened to the back of the head, and falling over, is tied by a leather strap under the chin. A blue shirt is generally worn; and a jereed and red slippers complete their equipment. Some of the better class of women wear trousers, and all adorn their persons according to their rank and importance. Both men and women have a singular custom of stuffing their nostrils with a twisted leaf of onions or clover, which has a very disgusting appearance. The natives have a variety of dances, two or three of which are peculiar to the country. In Mourzouk the luxuries of life are very limited, the people subsisting principally on dates. Many of them do not taste corn for months together; but when obtained, it is made into cakes, which are baked in ovens formed of clay in holes in the earth, and heated by burning wood. Tobacco is very generally chewed by the women, as well as by the men; but smoking is the amusement of a great man only.

The revenues of the sultan of Fezzan arise from slaves, merchandise, and dates. For every slave that enters his dominions he receives two Spanish dollars (in some years the number of slaves amounts to 4000); for a camel's load of oil or butter, seven dollars; for a load of beads, copper, or hardware, four dollars; and for one of clothing, three dollars. All Arabs who buy dates pay a dollar of duty on each load before they are allowed to remove it; an impost which, at times, is equal to the market price of the article. Above 3000 loads are sold to them annually. Date trees, excepting those of the kadi and Mamelukes, are taxed at the rate of one dollar for every 200. By this duty, in the neighbourhood of Mourzouk, or, more properly, in the few neighbouring villages, the sultan receives yearly about 10,000 dollars. Of all sheep or goats he is entitled to a fifth. On the sale of every slave he has, in addition to the head money, a dollar and a half, which, at the rate of 4000 slaves annually, gives 6000 dollars. The captured slaves are sold by auction, at which the sultan's brokers attend, bidding high only for the finest. The trees which are his private property produce about 6000 camel-loads of dates, each of 400lbs. weight, which may be estimated at about 18,000 dollars. Every garden pays a tenth part of the corn produced. The gardens are very small, and are watered with great labour from brackish wells, as rain is unknown, and dews never fall. Pomegranate trees and fig trees are sometimes planted in the water channels. Presents of slaves are frequently made, and fines levied. Each town pays a certain sum, which is small; but as the towns are numerous, the average amount may be estimated at 4000 dollars. Add to this the annual excursions for slaves, sometimes bringing 1000 or 1500, of which one fourth are the sultan's property, as well as the same proportion of camels. He alone can sell horses, which he buys for five or six dollars, when half starved, from the Arabs, who come to trade, and cannot maintain them, and makes a great profit by obtaining slaves in exchange for them. All his people are fed by the public, and he has no money to pay, excepting to the pasha, which was formerly 15,000 dollars per annum. There are various other modes by which he extorts money. If a man dies childless, the sultan inherits the greater part of his property; and if he thinks it necessary to kill a man, he becomes his sole heir.

In Mourzouk about a tenth part of the population are in a state of slavery. There are some white families, who are denominated Mamlukes, being descended from renegades, whom the pasha had presented to the former sultan. These families and their descendants are considered as noble, and, however poor and humble their situation may be, they are not a little vain of their title.

The general appearance of the men of Fezzan is plain, and their complexion is black; the women are of the same colour, and ugly in the extreme. Neither sex are remarkable for figure, height, strength, vigour, or activity; and they have a very peculiar cast of countenance, which distinguishes them from other blacks. But they are a cheerful people, fond of dancing and music, and obliging to each other. The men almost all read and write a little; but in every thing else they are very dull and heavy, their affections being cold and selfish, and a kind of general indifference to the common incidents of life marking all their actions. In Mourzouk the men drink a quantity of *lackbi*, as also a liquor called *busa*, which is prepared from dates. The Arabs generally practise hospitality; but amongst the Fezzanese that virtue does not exist. They are, however, very attentive and obsequious to those in whose power they are, or who can repay them tenfold for their pretended disinterestedness. Their religion enjoins that, should a stranger enter whilst they are at their meals, he must be invited to partake; but they generally contrive to evade this injunction by eating with closed doors. The lower classes are, from necessity, very industrious; but amongst people of rank industry is not a characteristic virtue. In regard to morals, they are much upon a level with the people of Tripoli, being both dishonest and insincere. Falsehood is not looked upon as odious unless it be detected.

The lower classes work neatly in leather; they weave a few coarse barracans, and work iron in a solid although clumsy manner. A few likewise work in gold and silver with tolerable skill; and every man is capable of acting as a carpenter or mason. The wood being that of the date tree, and the houses built of mud, very little elegance or skill is required in their construction.

From the constant communication with Bornou and with Soudan, the languages of both these countries are generally spoken, and many of their words are introduced into the Arabic; but the pronunciation is very different from that of the east. Their writing is in the Mogrebyn characters; but they have no idea of arithmetic, and reckon every thing by dots on the sand, ten in a line. Though very fond of poetry, they are incapable of composing it. The Arabs, however, compose a few little songs, which the natives have much pleasure in learning. The women are kept in a state of abject subordination, as is indeed common in all Mahommedan nations. The authority of parents over their children is very great, in fact, unnecessarily despotic. There are no written records of events among the Fezzanese, and their traditions are so disfigured, and so strangely mingled with religious and superstitious falsehoods, that no confidence whatever can be placed in them. Several scriptural passages are selected and believed. The Psalms of David, the Pentateuch, the books of Solomon, and many extracts from the inspired writers, are universally known, and most reverentially considered.

The only towns of any consideration in Fezzan, besides those already described, are Zuela, towards the eastern frontier, on the road to Egypt; Germa, to the west; and Garione, on the road to Bornou. In 1822, Dr Oudney and Captain Clapperton visited Germa, which lies towards the western frontier. It is a walled town, and surrounded by a ditch. At a little distance from it stands the remains of ancient Germa, which appears to have occupied more space than the modern town. It was formerly the capital of Fezzan, and once gave its name to the nation of the Garamantes; at least, unless there are two places of the same name, this must be the ancient Garama, which is described by Pliny as a fine city, the capital of Fazania. The inhabitants of the modern town are very poor, and many of the houses are in ruins. The aspect of the country between this place and Mourzouk is similar to that of the other portions of Fezzan which we have already described. The hills, which stand about a hundred yards apart, are composed of sandstone, finely interstratified with beds of blue and white pipe-clay and alum slate. There is a valley of considerable dimensions, and also several villages. The number of date trees in the eastern and western divisions of this valley is very great. There is here a town called Khraik, situated amidst some fine groves of palm trees, and possessing cultivated patches of ground and wells of good water.

The eastern and southern portions of Fezzan were visited by Captain Lyon. In latitude 25. 55. stands the town of Traghan, which was formerly a place as considerable as Mourzouk. It is situated in a flat desert plain, with its gardens and date groves at a short distance, and contains four mosques; but most of the houses, which are large, are in ruins, and the population is very trifling. Major Denham says that carpets are manufactured here equal to those of Constantinople. The route to Zuela lies entirely through salt plains and stony deserts, with here and there a small village. Zuela, or Zuila, is situated in latitude 26. 11. 48. It was formerly a considerable place, but is now only about a mile in circumference. It contains three mosques and three gates, but there are few good houses in it. The inhabitants are nearly all white; and Captain Lyon observes, that "they are certainly the most respectable, hospitable, and quiet people in Fezzan; and their whole appearance, for they are handsome, and very neatly dressed, bespeaks something superior to the other whites." At a short distance from Zuela are some very interesting ruins, one of them a castle, which must have been a place of great strength, on account of the immense thickness of the walls. These ruined fabrics have been much commented upon, but there is nothing to prove that they were of Roman origin. The next town of any importance is Gatrone, which stands in latitude 24. 47. 57. The country between Zuela and this place is a perfect desert, which in one place consists of a singular mixture of sand and salt. Gatrone is rather pleasantly situated. It is surrounded with sand hills and mounds of earth, covered with a small tree called *athali*. On leaving this place, Captain Lyon proceeded to Tegerhy, the southernmost town in Fezzan, and situated in lat. 24. 4. N. Here the cultivation of the date and palm ceases, and the Arabic gives place to the Bornouese language. The desert comes close to the walls of the town, which is situated to the southward of its palms. The dates are here very fine and plentiful. Tegerhy is commanded by a fort, containing wells of water within the walls. A range of low hills extends to the eastward; and near the town are some salt pools, which are frequented by snipes, wild ducks, and geese. The natives are black, and little superior to savages.

The kingdom of Fezzan is computed to contain about a hundred towns and villages, but the population is thought not to exceed 80,000. It is governed by a sultan, who, although in fact only a viceroy, dependent upon the pasha of Tripoli, possesses absolute sway. In regard to climate, Fezzan cannot be considered as fortunate. In summer the heat is intense, and the south wind, which is very dry, and impregnated with fiery particles, is scarcely supportable even by the natives. The winter, on the other hand, is accompanied with a bleak and penetrating wind blowing from the north, the cold of which is painfully felt even by the natives of a northern climate. Rain falls seldom, and in small quantities; thunder is also rare, but tempests of wind frequently occur. With regard to the soil, we have already spoken at sufficient length. The revenue, as derived from sources already mentioned, is devoted solely to the maintenance of the sultan, his army, and court. The cadi and other officers of justice, the ministers of religion, and even the great officers of state, are maintained from grounds set apart for this purpose, and which are covered usually with gardens, or woods of date trees. The office of cadi or chief judge, to which is also attached that of first minister of religion, is hereditary in a certain family. There is no regular army; but in time of war all who are able to carry arms may be called out.

This country was well known to the ancients under the title of the *Phazania Regio*, and the country of the Garamantes, whose ancient capital has been recognized by Major Rennell in the modern Germa, as already noticed. The name of Fasan or Fezzan seems to have been imposed by the Saracens, when they overran Northern Africa, and established the Mahommedan faith, and ever since it has continued to prevail.

FIAT, in *Law*, a short order or warrant signed by a judge, for making out and allowing certain processes.

FIBRARIÆ, a term anciently applied to minerals of a fibrous structure.

FIBRE, in *Anatomy*, a perfectly simple body, or at least as simple as any thing in the human structure, being fine and slender like a thread, and serving to knit together or connect other parts.

FIBRE is also used to denote one of the slender filaments which compose bodies, whether animal, vegetable, or mineral, but more especially a capillary root of plants.

FIBROSE, or FIBROUS, something consisting of fibres; as, for instance, the roots of plants.

FIBULA, in *Anatomy*, is the outer and smaller of the bones of the leg. See ANATOMY.

FIBULA, in *Antiquity*, a sort of button, buckle, or clasp, made use of by the Greeks and Romans for keeping close or fastening together certain parts of their clothes. The *fibulæ* were of various forms, and often adorned with precious stones. Both men and women wore them in their hair and on their shoes. Players and musicians, by way of preserving the voices of children placed under their care to learn their art, used to compress the prepuce with a *fibula*, lest they should have commerce with women.

Fichte.

FICHTE, JOHN THEOPHILUS, an eminent German metaphysician, was born at Rammenau, a village of Lusatia, on the 19th of May 1762. His father was a ribbon manufacturer, and carried on a small trade in haberdashery. A wealthy person in the neighbourhood having been struck with the extraordinary genius which young Fichte displayed, put him to school, in order to give him an opportunity of cultivating his talents; but the boy becoming impatient of restraint, ran off, and was found sitting on the banks of the Saale, with a map, on which he was endeavouring to trace the way to America. From this period he seems to have prosecuted his studies in an extremely desultory manner; occasionally attending the lectures of the professors of Wittemberg and Leipsic, without devoting his attention exclusively to any particular science. Theology, however, appears to have been his favourite study; and this predilection is conspicuous in many of his subsequent writings, which are distinguished by a singular mixture of philosophical and religious mysticism. When he left the university, his situation was by no means enviable. He possessed no fortune to enable him to indulge in the luxury of philosophical speculation; and, in spite of his decided aversion to every kind of constraint, he was compelled, by the necessity of his circumstances, to accept the situation of tutor in the family of a Prussian gentleman. But his residence in Prussia enabled him to cultivate the acquaintance of the celebrated philosopher of Königsberg, to whose judgment he submitted his first work, the *Critical Review of all Revelations*, which was published anonymously in 1792. In the literary journals, this production, which had attracted considerable attention, was ascribed to the pen of Kant, until the real author made himself known.

Having received fifty ducats from a Polish nobleman, in whose family he had been tutor, Fichte set out on a course of travels through Germany and Switzerland, and afterwards married a niece of Klopstock's at Zurich. In 1793, he published the first part of his *Contributions towards rectifying the Opinions of the Public respecting the French Revolution*. This book, which is written with considerable force and originality, created a great sensation in Germany, and was violently attacked, in consequence of a new and apparently dangerous theory which the author advanced relative to the social contract. The book, however, was perused with great avidity; but the attacks to which we have alluded probably prevented him from publishing the continuation.

The reputation of Fichte was now so well established, that he soon afterwards obtained an appointment to the philosophical chair at Jena, as successor to Reinhold, who had been called to the university of Kiel. Here he commenced his lectures by a programme, in which he endeavoured to give an idea of the *Doctrine of Science* (*Wissenschaftslehre*), the name by which he distinguished the principles of that system of transcendental idealism, which he afterwards more fully developed. In 1794, besides the ordinary duties of his professorship, he every Sunday gave a regular course of lectures, in the form of sermons, *On the Literary Calling*, which was numerously attended. Having established the principles of his doctrine of science, he endeavoured to extend their application to the several departments of philosophy; and with this view he published in 1796 his *Fundamental Principles of the Law of Nature*, and two years afterwards his *System of Morals*. In conjunction with Niethammer, he also published a philosophical journal, in which some articles were inserted, containing certain philosophical views of religion, which were considered by many as tending directly to atheism. Amongst a number of objectionable propositions, it was maintained that God was nothing else than the moral order of the universe; and that, to worship God as a being who could only be represented as existing in time and space, was a species of idolatry. One of Fichte's colleagues called the attention of the Saxon minister Burgsdorf to these heretical propositions; and the consequence was, the rigorous confiscation of the work throughout the whole of Saxony. Fichte and his friend Forberg wrote an *Appeal to the Public*, and several *Apologies*, in order to exculpate themselves from the imputation of atheism. The government of Weimar behaved on this occasion with prudence and moderation; but the celebrated Herder, vice-president of the consistory, took part against Fichte. Eberhard, on the other hand, although hostile to the metaphysical system of Fichte, undertook his defence. The controversy was carried on with great violence, and excited considerable ferment throughout the whole of Germany.

In the mean time Fichte resigned his professorship at Jena, and repaired to Berlin, where he met with a very flattering reception. Here his time was occupied in giving private lectures, and in composing his various writings. In 1800 he published a short treatise, entitled *The Exclusive Commercial State*, containing one of those philosophical systems of political economy from which the praise of ingenuity cannot be withheld; whilst, at the same time, the most cursory view of the general principles on which it is founded must be sufficient to convince us that it could never be advantageously reduced to practice.

About this period Fichte met with a formidable rival in Schelling, who had formerly been a warm partisan of the *Doctrine of Science*, but who now separated from his master, and propounded a new metaphysical theory of his own, which soon acquired a large share of popularity at the German universities, especially at Jena. Fichte indeed endeavoured to modify his theory of the *Doctrine of Science*, and to present it to the world in a new and more attractive form; but he never again recovered the sway which he had formerly exercised over the public mind. Meanwhile, his ardent wish to be again placed in an academical chair was at length gratified by M. de Hardenberg, who in 1805 procured for him the appointment of ordinary professor of philosophy in the university of Erlangen. This appointment was accompanied with the especial favour of being permitted to pass the winter at Berlin, in order to continue his lectures there. But this state of amphibious professorship, as his friends used to call it in jest, did not last long. During the summer of 1805 he delivered at Erlangen his celebrated lectures *On the Essence of the Literary Character* (*über das Wesen des Gelehrten*). The following winter he delivered to a numerous audience the course which he afterwards published under the title of *Guide to a Happy Life*. This was one of those publications in which he attempted to present his metaphysical doctrines to the public in all their sublimity, and, at the same time, with such clearness, as should render them intelligible to common readers.

The disasters which assailed the Prussian monarchy in 1806 were attended with serious consequences to Fichte. Erlangen having ceased to be a Prussian university, he did not await the entry of the French into Berlin, but fled to Königsberg, and thence proceeded to Riga. In the summer of 1807 he delivered a course of philosophical lectures at Konigsberg. The peace which ensued enabled him to return to Berlin, where he pronounced his famous *Orations to the German Nation*, which were enthusiastically read and applauded throughout all Germany. When the university of Berlin was founded, he obtained, through the interest of M. de Humboldt, the situation of rector, which secured to him an honourable revenue, whilst his rank, as first professor of philosophy, gave him great academical influence. His health, however, had suffered considerably from the shocks he had for some time experienced, and he found it necessary to have recourse to the waters of Bohemia, from which he derived great benefit. But his wife was attacked with a nervous fever, in consequence of her attendance on the deserted sick; and although she recovered, Fichte, whose affection would not allow him to leave her for a moment, caught the infection, and died on the 29th of January 1814.

Fichte was small in stature, but stout and well formed; his countenance was expressive of thoughtfulness and determination. In his intellectual character, genius was combined with inflexible firmness; and these qualities enabled him to surmount difficulties which would have overwhelmed a man of less vigorous temperament. In other respects his dispositions were amiable and his morals correct. It was in the academical chair that the genius of Fichte was manifested in its greatest splendour. It was said of him that he was born a professor; and there was indeed a charm in his manner of lecturing which had a powerful influence on the minds of his pupils, several of whom we have heard talk of him with enthusiasm. His fervid and brilliant eloquence, the clearness of his reasoning, and the simplicity and correctness of his language, seemed to diffuse a magic light and colouring over the darkest and most abstruse metaphysical problems. Those who were charmed with his eloquence were easily convinced by his reasoning, and became willing converts to his doctrines. His writings, especially those works in which his peculiar doctrines are propounded in a systematic form, are by no means so attractive as his lectures appear to have been. On the contrary, notwithstanding a constant affectation of strict and simple reasoning, his propositions are enveloped in such a degree of transcendental obscurity, as renders it extremely difficult to comprehend either the basis or the scope of that system of doctrines which he laboured to establish.

Hence it is far from being an easy matter to give an intelligible abstract of the principles of the *Doctrine of Science*, especially as we must necessarily presuppose some acquaintance, on the part of our readers, with the previous metaphysical labours of Kant. Fichte commenced his philosophical career precisely at that period when the writings of Kant had nearly obtained a paramount influence in the German schools, and when men even of superior talents thought it no mean glory to be able to comprehend and illustrate his doctrines. The Kantian theory was confessedly idealistic. Its celebrated author set out with an analysis of the cognitive faculty, and endeavoured to describe its various functions, as well as to ascertain the scope and limits of its legitimate exercise. All our knowledge, according to the critical philosophy, must have a reference to possible experience. Of external objects, or things in themselves (*noumena*), we can have no absolute knowledge; for we can know nothing but what is perceived by the senses, and cognized (if we may be allowed the expression) by our intellectual faculties, according to the laws peculiar to our constitution. These intellectual laws, or subjective forms, tend to combine our knowledge, and to render the field of experience a comprehensible whole. As we can have no knowledge of objects in themselves, but only of their *phænomena*, neither can we have any knowledge of things beyond the sphere of our experience, because these can neither be perceived by our senses nor subjected to the laws of the understanding. All reasoning, therefore, from mere ideas must necessarily be futile, because it has no reference to any corresponding object within the limits of experience. And although we can have no absolute knowledge of objects as they really exist, yet our knowledge of them possesses a subjective reality (that is, a reality with reference to the thinking subject), and may be said to correspond with the objects, because, from the nature of our intellectual constitution, we are incapable of receiving any other impression from them.

Reinhold was one of the earliest partisans of Kant, and one of the most ingenious and most popular commentators on the critical philosophy. But his talents were better adapted for explaining and illustrating the doctrines of others, than for discovering new truths, or inventing any original system of his own; and although an indefatigable student of philosophy, he seems to have never arrived at any settled conviction in metaphysical matters, but to have alternately adopted and abandoned every new theory which was successively presented to his view. After having been for some time enthusiastically devoted to the doctrines promulgated in the *Critical Review of Pure Reason*, which he esteemed the greatest masterpiece of philosophical genius, he at length discovered that Kant had neglected to secure the foundations of the edifice he had raised, and this defect he attempted to supply by his own *Theory of the Faculty of Perception* (*Theorie des Vorstellungsvermögens*). The main proposition laid down and illustrated in this work is nothing more nor less than this: We are compelled by consciousness to admit that every perception presupposes a percipient subject and an object perceived, both of which must be distinguished from the perception to which they relate; thus referring all our knowledge to consciousness as its ultimate principle. In the enunciation of this proposition there is nothing very new or original; but the illustration of this elementary doctrine, which, as a late reviewer of the German metaphysical theories observes, might have formed an excellent subject for a short philosophical dissertation of two or three sheets, is dilated into a work nearly as large as that to which it was intended to serve as a mere introduction; nor is the unnecessary length of the treatise in any measure compensated by the importance of the truths developed, or the ingenuity displayed in the research.

With greater talents and consistency, Fichte, who announced himself as a strict Kantian, attempted to resolve the same problem, and to develope a system which, by deducing all our knowledge from one simple principle, should give unity and stability to the critical theory. In his *Doctrine of Science* (*Wissenschaftslehre*), accordingly, he derives all our knowledge from the original act of the thinking subject in reflecting upon itself. *I am I* (which he expresses by the formula $A = A$), or the absolute position of the I by the I, is in itself the certain principle of all philosophy and of all our knowledge. But the creative energy of the I, in the course of this reflective process, goes still farther. By its own act, also, the I places the *not-I* (objects) as opposed to itself. In reflecting upon itself, as the absolutely active principle, it finds itself either determined by or determining the *not-I*. In the former case, it appears as the *intelligent I*; in the latter, as the *absolutely free, practical I*. Hence the distinction between theoretical and practical philosophy. The idea, then, which pervades the whole theory of Fichte is this: The I, or the thinking subject, is the absolutely active principle, which *constructs* the consciousness, and produces all that exists, by position, contraposition, and juxtaposition. The whole universe, in short, is the product of the I, or thinking subject.

We have thus endeavoured to give a very concise sketch of a theory which we shall not think of pursuing through its various ramifications, as we should despair of making it intelligible to our readers by any length of exposition. Fichte has been praised by his countrymen for his logical and consistent reasoning; but to us it appears that his theory proceeds entirely upon arbitrary assumptions, resting upon no solid foundation. That he displays considerable ingenuity in the development of his ideas we are willing to admit; but we are quite at a loss to perceive the merit of the theory he has advanced, when considered as a system of philosophical truths. The parade of scientific deduction which his reasoning exhibits may impose upon the incautious student; but a careful examination will undoubtedly convince him that the whole is a mere tissue of empty notions, derived from arbitrary and assumed principles.

In attempting to apply the principles of his doctrine of science to the theory of morals and the law of nature, Fichte exhibited many original and paradoxical opinions, along with some very just and ingenious philosophical observations. In his later writings he considerably modified his original theory of the doctrine of science, and produced a system of philosophical and religious mysticism, which appears to have given birth to the transcendental idealism of Schelling, an author who seems to have carried the extravagance of speculative reasoning to its utmost limits.

The following is a list of the works of Fichte.

1. *Versuch einer Kritik aller Offenbarung.* (Critical Review of all Revelation.) Königsberg, 1792, 1793, 8vo.
2. *Ueber den Begriff der Wissenschaftslehre.* (On the notion of a Doctrine of Science.) Jena, 1794, 8vo.
3. *Grundlage der gesammten Wissenschaftslehre.* (Foundation of the whole Doctrine of Science.) Ibid. 1794, 8vo.
4. *Grundriss des eigenthümlichen der Wissenschaftslehre.* (Sketch of the peculiarity of the Doctrine of Science.) Weimar, 1794.
5. *Vorlesungen ueber die Bestimmung des Gelehrten.* (Lectures on the Literary Calling.) Jena, 1794.
6. *System der Sittenlehre.* (System of the Doctrine of Morals.) Jena and Leipsic, 1795.
7. *Beyträge zur Berichtigung der Urtheile des Publicums ueber die Französische Revolution.* (Materials for Rectifying the Opinions of the Public respecting the French Revolution.)
8. *Grundlage des Naturrechts.* (Foundation of the Law of Nature.) Jena, 1796, 1797. 2 vols. 8vo.
9. *Appellation an das Publicum ueber die ihm beygemessenen atheistischen Aeusserungen.* (Appeal to the Public respecting the atheistical expressions imputed to him.) Jena and Leipsic, 1799.
10. *Ueber die Bestimmung des Menschen.* (On the Destiny of Man.)
11. *Der geschlossene Handlesstaat.* (The exclusive Commercial State.)
12. *Sonnenklarer Bericht an das grössere Publicum ueber das eigentliche Wesen der neuesten Philosophie.* (Luminous Report to the greater public on the peculiar Character of the modern Philosophy.) Berlin, 1801.
13. *Wissenschaftslehre.* (Doctrine of Science.) Tübingen, 1802, 8vo.
14. *Vorlesungen ueber das Wesen der Gelehrten.* (Lectures on the Literary Character.) Berlin, 1806.
15. *Die Grundzuge des gegenwärtigen Zeitalters.* (The Characteristics of the present age.) Ibid. 1806.
16. *Anweisung zum seligen Leben.* (Guide to a Happy Life.) Ibid. 1806.
17. *Reden an die Deutsche Nation.* (Discourses to the German nation.) Ibid. 1806.
18. *Die Wissenschaftslehre in ihrem allgemeinsten Umrisse dargestellt.* (The Doctrine of Science exhibited in its most general outline.) Ibid. 1810.
19. *Freidrich Nicolai's Leben und Sonderbare Meinungen, herausgegeben von Schlegel.* (Life and singular opinions of Frederic Nicolai, edited by Schlegel.) Tübingen, 1801.
20. *Antwortschrieben an K. L. Reinhold, auf dessen Beyträge zur leichtern Uebersicht des Zastandes der Philo-*

sophie, &c. (Answer to K. L. Reinhold, on his Materials for acquiring a more easy View of the State of Philosophy, &c.) Tübingen, 1801.

21. *Ueber die einzig mögliche Störung der academischen Freyheit.* (On the only possible disturbance of Academical Freedom.) Berlin, 1812.

22. *Ueber den Begriff des wahrhaften Kriegs, in Bezug auf den Krieg in jahre*, 1813. (On the notion of real war, with reference to the war in 1813.) Tübingen, 1815.

Fichte is also the author of several essays in periodical publications, and particularly in a philosophical journal edited by himself, with the assistance of Niethammer.

Those who are desirous of obtaining more minute information respecting Fichte's philosophical theory, may consult the following works: Tennemann's *Grundriss der Geschichte der Philosophie;* Degerando, *Histoire Comparée*, &c. W. T. Krug, *Briefe ueber die Wissenschaftslehre.* F. W. J. Schelling, *Darlegung des wahren Verhältnisses der Naturphilosophie zu der verbesserten Fichtischen Lehre.* J. Fries, *Reinhold, Fichte und Schelling.* C. F. Bachmann, *Ueber die Philosophie meiner Zeit.* Ancillon, *Essai sur le premier problème de la philosophie;* and *Essai sur l'existence et sur les derniers systèmes de métaphysique qui ont paru en Allemagne.* (K.)

FICINUS, Marsilius, a celebrated Italian, was born at Florence in 1433, and educated at the expense of Lorenzo de' Medicis. He attained a perfect knowledge of the Greek and Latin tongues, and became an eminent philosopher, physician, and divine. He was in the highest favour with Lorenzo and Cosmo de' Medicis, who appointed him a canon of the cathedral church of Florence. He applied himself intensely to the study of philosophy; and whilst others were striving who should be most deeply read in Aristotle, then the only philosopher in fashion, he devoted himself wholly to the study of Plato. He was indeed the first who restored the Platonic philosophy in the west; and for this purpose he translated into Latin the whole works of Plato. He next translated Plotinus; and afterwards the works, or at least part of them, of Proclus, Jamblicus, Porphyrius, and other celebrated Platonists. In his younger days Ficinus lived like a philosopher; too much so indeed, if it be true, as is said, that he did so to the neglect of piety. However, on the arrival of Savonarola at Florence, Ficinus went, with all the world, to hear his sermons; and whilst he attended them for the sake of the preacher's eloquence, he imbibed a strong sense of religion, and henceforward devoted himself more especially to its duties. He died at Correggio in 1499; and, as Baronius assures us, upon the testimony of authors whom he thinks credible, appeared immediately after his death to his friend Michael Mercatus, to whom, it seems, he had promised to manifest himself, in order to confirm what he had taught concerning the immortality of the soul. His writings, sacred and profane, which are very numerous, were collected and printed at Venice in 1516, at Basil in 1561 and 1576, and at Paris in 1641, in two vols. folio. Twelve books of his epistles, amongst which are many treatises, were printed separately in folio at Venice in 1495, and at Nuremberg in 1497, in 4to.

FICUS, the Fig Tree. The *ficus religiosa*, or banian tree, is a native of several parts of the East Indies. It has a woody stem, branching to a great height and vast extent, with heart-shaped entire leaves terminating in acute points. Some of these trees are of amazing size and extent, as they are continually increasing, and, contrary to most other things in animal and vegetable life, seem to be exempted from decay. Every branch from the main body throws out its own roots, at first in small tender fibres, several yards from the ground; but these continually grow thicker until they reach the surface, and then striking in, increase to large trunks, and become parent trees, shooting out new branches from the top, which again in time suspend their roots, and these, swelling into trunks, produce other branches; thus continuing in a state of progression as long as the earth, the parent of them all, contributes her sustenance. The Hindus are particularly fond of the banian tree, which, from its long duration, its outstretching arms, and overshadowing beneficence, they look upon as an emblem of the Deity. Near these trees the most esteemed pagodas are generally erected; under their shade the Brahmins spend their lives in religious solitude; and the natives of all castes and tribes are fond of recreating in the cool recesses, beautiful walks, and lovely vistas of this umbrageous canopy, impervious even to the direct rays of a tropical sun.

FIDD, an iron pin used at sea to splice or fasten ropes together, and made tapering and sharp at one end. There are also fidds of wood, which are much larger than those of iron.

Fidd-*Hammer* is used to signify a hammer, the handle of which is a fidd, or made tapering in that form.

FIDDES, Richard, a laborious English writer, was born at Hunmanby, near Scarborough, in the year 1671. Having received his grammatical education at a private school in the neighbourhood, he was admitted first of Corpus Christi, and then of University College, Oxford; but, after taking the degree of bachelor of arts, in 1693, he returned to his relations, and married the same year a lady of good family and fortune. In 1694 he was ordained priest, and not long afterwards presented to the rectory of Halsham; but this place, situated in a marsh, having proved insalubrious both to himself and his family, his residence on his benefice was dispensed with by his diocesan, upon which he removed to Wickham, where he continued for some time. Being thus unable to display his talents as a preacher, and having a numerous family to support, he resolved to devote himself to literature, and with this view proceeded to London in 1712, where, by the favour of Swift, he was introduced to the Earl of Oxford, who made him one of his chaplains, and procured for him a similar appointment from the queen. But the change of ministry in 1714 overturned all Fiddes' hopes of preferment, and forced him to apply to writing with greater assiduity than ever. Yet he continued to enjoy the esteem of contemporary writers, particularly those of his own party, and was honoured with the friendship of some of the most eminent men of the time. By the interposition of Dr Radcliffe, the degree of bachelor of divinity was conferred upon him by diploma, in the beginning of 1713; and, in 1718, he was honoured with that of doctor by the university of Oxford. In 1725 he died in the house of a friend at Putney, leaving a wife and six children, one of whom, his eldest daughter, married Mr Barcroft, curate of St George's, Hanover Square, who abridged Taylor's *Ductor Dubitantium.* Dr Fiddes was the author of, 1. A Prefatory Epistle concerning some Remarks to be published on Homer's Iliad, occasioned by the proposals of Mr Pope towards a new English version of that poem, 1714, in 12mo; 2. *Theologica Speculativa*, or the first part of a body of Divinity under that title, wherein are explained the principles of Natural and Revealed Religion, 1718, folio; 3. Fifty-two Practical Discourses on several subjects; 4. The Life of Cardinal Wolsey, 1724, folio; 5. Answer to Britannicus, compiler of the London Journal, 1725, being a defence of the Life of Wolsey; 6. A general Treatise of Morality, formed upon the principles of Natural Reason only, 1724, in 8vo; 7. A Preparative to the Lord's Supper; and, 8. A Letter in answer to one from a Freethinker, occasioned by the Duke of Buckingham's Epitaph. Dr Fiddes was an ingenious but not very learned man; he possessed a retentive memory, and was capable of the most intense application ; but his style as a writer is tedious and prolix, and, though commonly judicious, he almost never rises above mediocrity. His misfortunes, towards the close of his life, were chiefly owing to his connection with that party in the state to which, through Swift, he had been led to attach himself upon his arrival in London. (A.)

FIDDLE. See Violin.

FIDE-JUSSOR, in the *Civil Law*, is a surety, or one who obliges himself in the same contract with a principal, for the greater security of the creditor or stipulator.

FIDEI-COMMISSUM, in the *Civil Law*, an estate left in trust with any person, for the use of another.

FIDES, Faith, or Fidelity, one of the virtues deified by the Pagans. She had a temple near the capitol, founded by Numa Pompilius ; but no animals were immolated, nor was any blood spilt, in her sacrifices. During the performance of her rites, her priests appeared in white vestments, with their heads and hands covered with linen, to show that fidelity ought to be sacred.

FIDIUS, in Pagan worship, a god who presided over alliances and promises. This deity, which the Romans borrowed from the Sabines, was also called *Sanctus*, *Semon*, and *Semi-Pater*.

FIELD, in *Heraldry*, is the whole surface of the shield or the continent, so called because it contains those achievements anciently acquired in the field of battle. It is the ground on which the colours, bearing, metals, furs, charges, and the like, are represented.

Field-Book, in *Surveying*, a book in which the angles, stations, distances, &c. are set down.

Field-Colours, or *Camp-Colours*, in war, are small flags of about a foot and a half square, which are carried along with the quartermaster-general, to mark out the ground for the squadrons and battalions.

Field-Pieces, cannons of small calibre, from three to twelve pounders, which are carried along with an army in the field.

Field-Works, in *Fortification*. See Fortification.

FIELDING, Henry, the prince of English novellists, was born at Sharpham-Park, Somersetshire, on the 22d of April 1707. His father, General Edmund Fielding, who had served under John duke of Marlborough, was the third son of Dr John Fielding, canon of Salisbury, who was the fifth son of George earl of Desmond, and brother of William the third earl of Denbigh ; and his mother, the general's first wife, was a daughter of Judge Gould. He was also connected with the noble family of Kingston, which, in the celebrated Lady Mary Wortley Montague, boasted a brighter ornament than rank or title could bestow. Henry Fielding was the only son of the first marriage ; but he had four sisters of the full blood, one of whom, Sarah, was distinguished as an authoress by the history of *David Simple*, and other literary attempts. General Fielding, after the death of his first wife, married a second time, and had a numerous family of sons, one of whom is still remembered as a judge of police by the title of Sir John Fielding. The expense attending so large a family, together with a natural thoughtlessness of disposition on the part of his father, of whose habits economy formed no part, were probably the occasion of Henry being early involved in those embarrassments with which, excepting at brief intervals, he continued to struggle through life.

After acquiring the rudiments of education under the Rev. Mr Oliver, who is supposed to have furnished him with the outline of Parson Trulliber's character, young Fielding was removed to Eton, where he made great progress in the study of the Greek and Roman authors, and imbibed that deep love of classical literature which may be traced throughout all his works. As his father destined him for the bar, he was, at the age of eighteen, sent from Eton to Leyden, where he remained about two years, and is said to have given the most earnest attention to the study of the civil law. Had he been permitted to continue the pursuit in which he had thus engaged, the courts would probably have gained an accomplished lawyer, and the world would have lost a man of genius ; but the circumstances of the father determined the chance in favour of posterity, though against the interests and perhaps the welfare of the son. Remittances, in short, failed, and the young civilian was compelled to return, at the age of twenty, to plunge into the dissipation of London, without a monitor to warn or a friend to support him. His father had indeed promised him an allowance of two hundred pounds a year ; but this, as Fielding himself used to observe, any one might pay who would. Possessed of a strong constitution, a lively imagination, and a keen relish of pleasure, with the capacity of enjoying the present and trusting to chance for the future, Fielding thus found himself his own master in a place where the temptations to every expensive indulgence are numerous, and the means of gratification easily attainable ; and, with reckless improvidence, he squandered in pursuit of pleasure the scanty means which, with strict economy, might have enabled him to begin the world, at the same time entailing upon himself those distresses and misfortunes in which he was ever afterwards involved.

But as disagreeable impressions never remained long upon his mind, and as it was his disposition to look at the brighter side of things, or rather to enliven the gloomiest prospect with the colours which his own fancy cast upon it, he flattered himself that he would find resources in his own wit and genius, and that the difficulties in which he was involved would be overcome by the exertions which he conceived himself capable of making to surmount them. To a man of pleasure, in fact, some resources were indispensably necessary, and Fielding found them in his pen, having no alternative, as he himself used to say, but to become a hackney writer or a hackney coachman. He at first employed himself in writing for the stage, then in high reputation, from having recently engaged the talents of Wycherley, Congreve, Vanburgh, and Farquhar ; his comedies and farces were brought out in hasty succession ; between the years 1727 and 1736, play succeeded play, to the number of eighteen, which were struck off as his necessities impelled, and sank oftener than swam in the theatrical sea upon which he cast them. Of these, the only pieces now known or read are the mock-tragedy of *Tom Thumb*, the translated play of *The Miser*, and the farces of *The Mock-Doctor* and *Intriguing Chambermaid* ; and yet, as Sir Walter Scott justly observes, they are all the production of an author unrivalled for his conception and illustration of character in the kindred department of imaginary narrative. Whilst Fielding was thus living as a man of wit and pleasure about town, seeking and finding amusement in scenes of gaiety and dissipation, and endeavouring to discharge the expense incidental to such a life by the precarious resources afforded by the stage, which, as may easily be supposed, were inadequate for the purpose, he attempted to improve his circumstances by becoming himself the manager of a company ; and having, in 1735, assembled a number of discarded comedians, he proposed that they should perform his own plays, at the little theatre of the Haymarket, under the whimsical title of the Great Mogul's company of comedians. But the project, as might have been expected, did not succeed ; and the company, which seemed to have dropped from the clouds, were under the necessity of disbanding. The whole scheme, in fact, has more the air of a mad frolic than of a serious undertaking. During his theatrical career, which, we have just seen, was by no means brilliant, Fielding, like most authors of the time, found it impossible to interest the public sufficiently in the various attempts which he made to gain their favour, without condescending to flatter their political animosities. In two of his dramatic pieces, *Pasquin* and the *Historical Register*, he displays great acrimony against Sir Robert Walpole, whom, in the year 1730, he had in vain attempted to propitiate by some courtly verses. The keenness of the satire made it felt, and its freedom is supposed to have operated considerably in producing a measure which was then thought necessary to restrain the licentiousness of the stage, and to check that proneness to personal and political satire which had been fostered by the success of the *Beggars' Opera.* But this measure, which consisted in vesting a discretionary power in the Lord Chamberlain to refuse a license to any piece which he should disapprove, was very unpopular at the time, and, like all petty legislation, has done mischief which was not intended by it, and failed to accomplish the object for which it was designed.[1]

About the year 1736, Fielding having, it seems, formed the resolution of settling in life, espoused a young lady of Salisbury, named Craddock, possessed of considerable beauty, and of a fortune of L.1500; and, about the same time, he succeeded, in right of his mother, to a small estate of L.200 per annum, situated at Stower in Derbyshire. With this fortune, which, managed with prudence and economy, might have afforded a decent competence, he retired from London to his seat in the country, resolved to bid adieu to the follies and irregularities of a town life, and to cultivate habits of domestic enjoyment. But having unfortunately carried with him the same improvident disposition to enjoy the present at the expense of the future, which marked his whole life, he soon forgot all his resolutions of amendment; established an equipage with showy liveries; threw open his gates to unbounded hospitality; and suffered his whole substance to be devoured by horses, hounds, retinue, and entertainments. Thus, in less than three years, Fielding found himself landless, homeless, penniless, without any other resource than his abilities, and having brought nothing from the country except that experience of rural life and its pleasures which afterwards enabled him to delineate with such inimitable truth and force the character of Squire Western. Not discouraged, however, he entered himself as a student of law at the Temple, and, after the customary term of manducation, was called to the bar. Fielding had now a profession, and, as he had vigorously applied his powerful mind to the study of the law, it might have been expected that his success would have been in proportion to his assiduity. But various causes conspired to obstruct his rise in the legal profession. In the first place, those persons who have it in their power to advance or retard the practice of a young lawyer, seem to have mistrusted the capacity of a man of wit and pleasure for steady application to business; and Fielding's own conduct was in all probability such as to justify this want of confidence in his regularity. In the next place, disease, the consequence of a free life, came to the aid of dissipation of mind, and interrupted the course of his practice by severe attacks of the gout, which gradually undermined his naturally robust constitution. But amidst all this difficulty and suffering, he pursued his researches with great though irregular vigour; and, as a proof of the eminence to which, in happier circumstances, he might have risen at the bar, he left two manuscript volumes in folio on the Crown Law; a branch to which he had most assiduously applied himself. The exigencies of a family, to which he was tenderly attached, forced him however to have recourse again to the stage, where he attempted to produce a continuation of his own piece, *The Virgin Unmasked;* but as one of the characters was supposed to have been written in ridicule of a man of quality, the Lord Chamberlain refused his license. Political pamphlets, fugitive tracts, newspaper essays, and sometimes farces, were the next means he had recourse to for subsistence; and as his ready pen supplied such productions upon every emergency, he contrived out of the scanty profits to support himself and family. But amidst the anxiety and labour of this precarious mode of life, he had the misfortune to lose his wife; a domestic calamity which so deeply affected him that his reason was for a time endangered by the excess of his grief. All violent emotions, however, are happily transient; Fielding recovered from the blow which had stunned him, though his regret was lasting; and the necessity of procuring subsistence compelled him to resume his literary labours. At length, in the year 1741 or 1742, circumstances led him to engage in a species of composition which he rescued from the degraded state in which he found it, and rendered a classical department in English literature.

The novel of *Pamela*, published in 1740, having raised the fame of Richardson to the highest pitch, Fielding, whether tired of hearing it overpraised,[2] or whether, as a writer for subsistence, disposed to catch at whatever interested the public for the time, or whether, finally, seduced by that malicious spirit of wit which delights to turn into ridicule the idol of the day, resolved to caricature the style, the principles, and the personages of this favourite performance. As Gay's desire to satirize Philips produced *The Shepherd's Week*, so Fielding's purpose to ridicule *Pamela* suggested *The History of Joseph Andrews;* but, in both cases, more especially the latter, a work was executed of infinitely greater merit than could have been expected to arise out of such a design; and the reader received a higher gratification than the author himself appears to have proposed or contemplated. In Fielding's novel there is indeed a fine vein of irony, as will appear from comparing it with the pages of *Pamela;* but the production against which the ridicule was directed is now almost forgotten; whilst *Joseph Andrews* continues to be read for its admirable pictures of manners, and, above all, for the inimitable character of Parson Adams, which alone is sufficient to decide the superiority of Fielding over all novel writers. "His learning, his simplicity, his evangelical purity of mind," says Sir Walter Scott, "are so admirably mingled with pedantry, absence of mind, and the habit of athletic and gymnastic exercises, then acquired at the universities by students of all descriptions, that he may be safely termed one of the richest productions of the muse of fiction. Like Don Quixote, Parson Adams is beaten a little too much and too often; but the cudgel lights upon his shoulders, as on those of the honoured knight of La Mancha, without the slightest stain to his reputation; and he is bastinadoed without being degraded."[1] *Joseph Andrews* was eminently successful; and poor Richardson, whose greediness of praise was only equalled by his extreme sensitiveness to ridicule, felt proportionally offended; whilst his admirers, male and female, took care to echo back his resentment, and to heap Fielding with reproach. The animosity of the idol and his worshippers, in fact, survived the gifted man who had rendered them all ridiculous; and in Richardson's correspondence we find the most ungenerous, not to say malignant, reproaches cast on his memory.[2] But Fielding does not appear to have retorted any of the ill-will in which Richardson and his coterie indulged. If he gave the first offence without provocation, he was also the first to retreat from the contest, and to leave his exasperated antagonists in undisputed possession of the field. Nor was Fielding slow in conceding to Richardson that praise to which his genius entitled him from the liberality of his contemporaries. In the fifth number of the *Jacobite Journal*, he warmly commends *Clarissa Harlowe*, by far the best and most powerful of Richardson's novels, and which, with those scenes in *Sir Charles Grandison* relating to the history of Clementina, contains the passages of deep pathos on which his fame as a writer must finally rest. "Perhaps this is one of the cases," says Sir Walter Scott, "in which one would rather have sympathized with the thoughtless offender, than with the illiberal and ungenerous mind which so long retained its resentment."

---

[1] "The regulation," says Sir Walter Scott, "was the cause of much clamour at the time; but licentious satire has since found so many convenient modes of access to the public, that its exclusion from the stage is no longer a matter of interest or regret; nor is it now deemed a violent aggression on liberty that contending political parties cannot be brought into collision within the walls of the theatres, intended, as they are, for places of amusement, not for scenes of party struggle." (*Memoir of Fielding.*) This is no doubt true; but has not the theatre suffered in consequence of the regulation by which all political allusions are excluded from the stage, whilst neither the amount of licentious satire, nor its facilities of gaining access to the public, have been, in the slightest degree, diminished?

[2] This production, many passages of which would now be thought highly indelicate, and condemned as suggestive of licentious ideas, was in those days recommended even from the pulpit. Modern refinement, though it may not have succeeded in banishing immodesty from the heart, has at least had the effect of purifying literary compositions of that grossness which, more or less, deforms almost all those of the last age.

After the publication of *Joseph Andrews*, Fielding had again recourse to the stage, and brought out *The Wedding-Day*, which, though upon the whole unsuccessful, produced him some little profit. This was the last of his theatrical efforts which appeared during his life-time. The comedy of *The Fathers*, in manuscript, was lost by Sir Charles Hanbury Williams, and, when recovered, was performed after the author's death, for the benefit of his family.[3] Besides a variety of fugitive pieces, Fielding published, in 1743, a volume of miscellanies, containing, amongst other things, *The Journey from this World to the next*; a tract of which it is difficult to perceive the scope or aim, although it displays a good deal of Fielding's characteristic humour. His next production was *The History of Jonathan Wild the Great*; a picture of desperate vice, unrelieved by a single indication of human feeling, or even by an accidental deviation into virtue. What object Fielding could have proposed to himself by so revolting a delineation, it is not easy to conjecture. For, besides the disgust produced by the contemplation of wickedness naked and unredeemed, every one must feel, that ascribing a train of fictitious adventures to a real character, has in it something clumsy and inartificial; whilst, on the other hand, it subjects the author to a suspicion of having used as the title of his book the name of an infamous depredator, in the hope of connecting the one with the popular renown of the other. At the same time, there are not many passages in Fielding's works more strongly marked with his peculiar genius, than the scene between Jonathan Wild and the Ordinary, in Newgate. Besides these more permanent proofs of his application to literature, Fielding employed his ready pen in most of the political and literary controversies of the times. He conducted one paper, called *The Jacobite Journal*, the object of which was to eradicate those feelings and sentiments which had already been so effectually crushed on the field of Culloden; and he either entirely composed or had a principal share in *The True Patriot* and *The Champion*, periodicals of the same class. Being attached to the principles of the Revolution, and to the settlement of the succession in the family of Brunswick, he steadily advocated what was then called the Whig cause; but whilst far inferior writers were enriched out of the secret-service money with unexampled prodigality, his zeal and ability remained long unnoticed, and never met with any suitable recompense.

As it was impossible, however, that such a man could be altogether overlooked, Fielding, in 1749, received a small pension, together with an appointment as a justice of peace for Westminster; an office then considered as disreputable, and of which he was at liberty to make the most he could by the worst means he chose. At this period the magistrates of Westminster, being paid by fees for their services to the public, were thence termed trading justices; and in general they appear to have deserved this opprobrious appellation; for the mean and wretched system on which they were remunerated making it their interest to inflame petty disputes, to wring out of thieves and pickpockets a portion of their unhallowed gains, and thus to traffic, as it were, in guilt and misery, seemed equally well calculated to encourage crime, and to degrade those whose ostensible duty it was to repress it. The habits of Fielding, who was never very select in his society, cannot be supposed to have been improved by the position into which he was now thrown; and from a humiliating anecdote told by Horace Walpole,[1] in his usual lively but unfeeling manner, it would appear, even after allowance is made for the aristocratical exaggeration of the narrator, that his mind had sunk to the level of his situation. Yet, though the circumstances attending his official situation tended to foster the careless and disreputable habits which he was unfortunately but too prone to indulge, it is consoling to observe that Fielding's principles remained unshaken, and that there is no foundation whatever for the imputation of venality which, from the popular discredit attaching to his office, and his own thoughtless extravagance, the ill-natured world were at one time but too ready to cast upon him. His own account of his conduct respecting the dues of the office on which he depended for subsistence has been confirmed by Mr Murphy, and never doubted or denied. "I will confess," says he, "that my private affairs at the beginning of winter had but a gloomy aspect; for I had not plundered the public, or the poor, of those sums which men, who are always ready to plunder both as much as they can, have been pleased to suspect me of taking; on the contrary, by composing instead of inflaming the quarrels of porters and beggars (which, I blush when I say, hath not been universally practised), and by refusing to take a shilling from a man who most undoubtedly would not have had another left, I had reduced an income of L.500 a year, of the dirtiest money upon earth, to little more than L.300, a considerable portion of which remained with my clerk." Nor was this all. Whilst Fielding thus evinced his disinterestedness as a magistrate, he endeavoured, by various suggestions, to check the growth of crime and depravity. His *Inquiry into the Increase of Thieves and Robbers* contains several valuable hints which succeeding statesmen have adopted, and some which have not yet received the attention they deserve. He was the first to expose the injurious effects of the frequency of pardons, rendered necessary by the reckless multiplication of capital punishments; and he had the merit of directing public attention to that swelling imposthume of the state, pauperism, with the consequences to be apprehended from the state of the poor laws and the mode in which they were administered. He afterwards published a scheme for the provision of the poor, which showed that he was fully sensible of the evil, without being able to suggest an effectual or practical remedy; but although his project for restricting them to their parishes, and providing for them in workhouses, was not approved of, it has never been disputed that his treatise exhibits both the knowledge of the magistrate and the picturesque expression of the novel writer. He also published a *Charge to the Grand Jury of Middlesex*, and some *Tracts concerning Law Trials*, which are considered as valuable.

---

[1] The style of this piece is said in the preface to be an imitation of Cervantes; but it bears more resemblance to that of the *Roman Comique* of Scarron, from whom Fielding appears to have copied the mock-heroic style, which narrates ludicrous events in the language of the classical epic; a vein of pleasantry, however, which is soon wrought out, and which, if frequently employed, is apt to degenerate into pedantry.

[2] Richardson, being well acquainted with Fielding's sisters, took occasion to complain to them, not of their brother's usage of himself (this would have been natural and honest), but of his unfortunate predilection for what was mean and low in character and description. The following passage is remarkable, first for the unexampled presumption of the writer, who thus constitutes himself the judge paramount of Fielding's qualities; and, secondly, for the malignant indelicacy which could obtrude such observations on the sister of a rival: "Poor Fielding! I could not help telling his sister that I was equally surprised at and concerned for his continued lowness. Had your brother, said I, been born in a stable, or been a runner at a spunging-house, one should have thought him a genius, and wished he had had the advantage of a liberal education, and of being admitted into good company!" The man who could be guilty of such deliberate brutality as is here complacently chronicled, would not have scrupled to employ more criminal means to gratify his animosity, if he had not been restrained either by innate cowardice or a salutary fear of the laws. After this, however, we cannot be surprised to find Richardson alleging that Fielding was destitute of invention and talents; that the run of his best works was nearly over; and that, as an author, he would soon be forgotten!

[3] The following anecdote, which is given by former biographers, shows the carelessness of Fielding respecting his reputation as a dramatist: "On one of the days of its rehearsal (that is, the rehearsal of *The Wedding-Day*), Garrick, who performed a principal part, and who was then a favourite with the public, told Fielding he was apprehensive that the audience would make free with him in a particular passage, and remarked that, as a repulse might disconcert him during the remainder of the night, the passage should be omitted; "No, d—n 'em," replied he; "if the scene is not a good one, let them find *that* out." Accordingly the play was brought out without alteration, and, as had been foreseen, marks of disapprobation appeared. Garrick, alarmed at the hisses he met with, retired into the green-room, where the author was solacing himself with a bottle of champagne. He had by this time drank pretty freely; and, glancing his eye at the actor, while clouds of tobacco issued from his mouth, cried out, "What's the matter, Garrick? what are they hissing now?" "Why, the scene that I begged you to retrench," replied the actor; "I knew it would not do; and they have so frightened me that I shall not be able to collect myself again the whole night." "Oh, d—n 'em," rejoined he, with great coolness, "they *have* found it out, have they?"

Before publishing his scheme for the provision of the poor, however, Fielding made himself immortal by the production of *Tom Jones, or the History of a Foundling;* a work composed under all the disadvantages incident to an author alternately harassed by his disagreeable magisterial duties, and pressed by the necessity of hurrying out some ephemeral essay or pamphlet to meet the demands of the passing day.[2] In these painful and precarious circumstances was the first of English novels given to the public, who had not hitherto seen any works founded upon the plan of painting from nature, and who, consequently, were quite unprepared for a work constructed on such a principle. Even Richardson's novels are but a step removed from the domain of the old romance; and, though approaching more nearly to the ordinary course of events, still resemble it by dealing in improbable incidents, exaggerated delineations, and characters swelled out beyond the ordinary proportions of humanity. *Tom Jones*, on the other hand, is truth and human nature itself, and therein consists the incalculable advantage which it possesses over all previous fictions of this particular kind. Fielding is the Hogarth of novelists; and he painted manners with the hand of a master. *The History of a Foundling* was received with unanimous acclamation by the public, and proved so productive to Millar, the publisher, that he handsomely added L.100 to the L.600 for which he had purchased the work from the author.

"The general merits of this popular and delightful work," says Sir Walter Scott, "have been so often dwelt upon, and its imperfections so frequently censured, that we can do little more than hastily run over ground which has been so repeatedly occupied. The felicitous contrivance and happy extrication of the story, where every incident tells upon and advances the catastrophe, while at the same time it illustrates the characters of those interested in its approach, cannot too often be mentioned with the highest approbation. The attention of the reader is never diverted or puzzled by unnecessary digressions, or recalled to the main story by abrupt and startling recurrences; he glides down the narrative like a boat on the surface of some broad navigable stream, which only winds enough to gratify the voyager with the varied beauty of its banks. One exception to this praise, otherwise so well merited, occurs in the story of the Old Man of the Hill; an episode which, in compliance with a custom introduced by Cervantes, and followed by Le Sage, Fielding has thrust into the midst of his narrative, as he had formerly introduced the History of Leonora, equally unnecessarily and inartificially, into that of *Joseph Andrews*. It has also been wondered why Fielding should have chosen to leave the stain of illegitimacy on the birth of his hero; and it has been surmised that he did so in allusion to his own first wife, who was also a natural child. A better reason may be discovered in the story itself; for had Miss Bridget been privately married to the father of Tom Jones, there could have been no adequate motive assigned for keeping his birth secret from a man so reasonable and compassionate as Allworthy.

---

[1] "Rigby gave me a strong picture of nature. He and Peter Bathurst, t'other night, carried a servant of the latter's, who had attempted to shoot him, before Fielding, who, to all his other vocations, has, by the grace of Mr Lyttleton, added that of Middlesex justice. He sent them word he was at supper; they must come next morning. They did not understand that freedom, and ran up, where they found him banquetting with a blind man, a wh—, and three Irishmen, on some cold mutton, and a bone of ham, both in one dish, and the dirtiest cloth. He never stirred or asked them to sit. Rigby, who had seen him come so often to beg a guinea of Sir C. Williams, and Bathurst, at whose father's he had lived for victuals, understood that dignity as little, and pulled themselves chairs, on which he civilized." (*Letters from the Hon. Horace Walpole to George Montague, Esq.* p. 58, London, 1818.) It ought to be added, however, that Walpole, though he has here stigmatized the lowness of Fielding's society and habits, has elsewhere done justice to his talents. In *The Parish Register of Twickenham*, or poetical account of that place, Fielding's residence in the neighbourhood is not forgotten; that residence,

Where Fielding met his bunter muse,
And as they quaff'd the fiery juice,
Droll nature stamp'd each lucky hit
With unimaginable wit.

[2] *Tom Jones* is inscribed to the Hon. Mr, afterwards Lord Lyttleton, in a dedication where he intimates that, without his assistance, and that of the Duke of Bedford, the work would never have been composed, inasmuch as the author had been indebted to them for the means of subsistence whilst engaged in composing it. Ralph Allen, the friend of Pope, is also alluded to as one of his benefactors, but, by his own desire, not named. This modest and munificent patron of merit is said to have made Fielding a present of L.200 at one time, and that before he was personally acquainted with the object of his bounty; an act of rare generosity, and, from the manner in which it was performed, fully confirming the truth of Pope's beautiful couplet:—

Let modest Allen, with ingenuous shame,
Do good by stealth, and blush to find it fame.

"But even the high praise due to the construction and arrangement of the story is inferior to that claimed by the truth, force, and spirit of the characters, from Tom Jones himself down to Black George the game-keeper and his family. Amongst these, Squire Western stands alone; imitated from no prototype, and in himself an inimitable picture of ignorance, prejudice, irascibility, and rusticity, united with natural shrewdness, constitutional good humour, and an instinctive affection for his daughter,—all which qualities, good and bad, are grounded upon that basis of thorough selfishness, natural to one bred up from infancy where no one dared to contradict his arguments or to control his conduct. In one incident alone we think Fielding has departed from this admirable sketch. As an English squire, Western ought not to have taken a beating so unresistingly from the friend of Lord Fellamar. We half suspect that the passage is an interpolation. It is inconsistent with the squire's readiness to engage in rustic affrays. We grant a pistol or sword might have appalled him; but Squire Western should have yielded to no one in the use of the English horsewhip; and as, with all his brutalities, we have a sneaking interest in the honest jolly country gentleman, we would willingly hope there is some mistake in this matter.

"The character of Jones, otherwise a model of generosity, openness, manly spirit, mingled with thoughtless dissipation, is, in like manner, unnecessarily degraded by the nature of his intercourse with Lady Bellaston; and this is one of the circumstances which incline us to believe that Fielding's ideas of what was gentleman-like and honourable had sustained some depreciation, in consequence of the unhappy circumstances of his life, and of the society to which they condemned him.

"A more sweeping and general objection was made against the *History of a Foundling* by the admirers of Richardson, and has been often repeated since. It is alleged, that the ultimate moral of *Tom Jones*, which conducts to happiness, and holds up to our sympathy and esteem a youth who gives way to licentious habits, is detrimental to society, and tends to encourage the youthful reader in the practice of those follies to which his natural passions and the usual course of the world but too much direct him. French delicacy, which on so many occasions has strained at a gnat and swallowed a camel, saw this fatal tendency in the work, and by an *arrêt* discharged the circulation of a bungled abridgment by De la Place, entitled a translation. To this charge Fielding himself might probably have replied, that the vices into which Jones suffers himself to fall are made the direct cause of placing him in the distressful situation which he occupies during the greater part of the narrative; whilst his generosity, his charity, and his amiable qualities, become the means of saving him from the consequences of his folly. But we suspect with Dr Johnson, that there is something of cant both in the objection and in the answer to it. 'Men,' says that moralist, 'will not become highwaymen because Macheath is acquitted on the stage;' and we add, they will not become swindlers and thieves because they sympathize with the fortunes of the witty picaroon Gil Blas, or licentious debauchees because they read *Tom Jones*. The professed moral of a piece is usually what the reader is least interested in; it is like the mendicant, who cripples after some splendid and gay procession, and in vain solicits the attention of those who have been gazing upon it. Excluding from consideration those infamous works, which address themselves directly to awakening the grosser passions of our nature, we are inclined to think, the worst evil to be apprehended from the perusal of novels is, that the habit is apt to generate an indisposition to real history and useful literature; and that the best which can be hoped is, that they may sometimes instruct the youthful mind by real pictures of life, and sometimes awaken their better feelings and sympathies by strains of generous sentiment and tales of fictitious wo. Beyond this point they are a mere elegance, a luxury contrived for the amusement of polished life, and the gratification of that half love of literature, which pervades all ranks in an advanced stage of society, and are read much more for amusement than with the least hope of deriving instruction from them. The vices and follies of Tom Jones are those which the world soon teaches to all who enter on the career of life, and to which society is unhappily but too indulgent; nor do we believe, that in any one instance the perusal of Fielding's novel has added one libertine to the large list, who would not have been such had it never crossed the press. And it is with concern we add our sincere belief, that the fine picture of frankness and generosity exhibited in that fictitious character has had as few imitators as the career of his follies. Let it not be supposed that we are indifferent to morality, because we treat with scorn that affectation which, while in common life it connives at the open practice of libertinism, pretends to detest the memory of an author who painted life as it was, with all its shades, and more than all the lights which it occasionally exhibits, to relieve them. For particular passages of the work, the author can only be defended under the custom of his age, which permitted, in certain cases, much stronger language than ours. He has himself said, that there is nothing which can offend the chastest eye in the perusal; and he spoke probably according to the ideas of his time. But in modern estimation, there are several passages at which delicacy may justly take offence; and we can only say, that they may be termed rather jocularly coarse than seductive; and that they are atoned for by the admirable mixture of wit and argument by which, in others, the cause of true religion and virtue is supported and advanced.

"Fielding considered his works as an experiment in British literature; and therefore he chose to prefix a preliminary chapter to each book, explanatory of his own views, and of the rules attached to this mode of composition. Those critical introductions, which rather interrupt the course of the story, and the flow of the interest at the first perusal, are found, on a second or third, the most entertaining chapters of the whole work."

The publication of *Tom Jones* placed Fielding at the head of English novellists, but it seems to have been attended with little or no advantage to his fortune beyond the temporary relief afforded by the copy-money. His last work of importance was *Amelia*, which may be considered as a continuation of *Tom Jones;* but we have not the same sympathy for the ungrateful and dissolute conduct of Booth, as for the youthful, and on that account somewhat excusable, follies of Jones. The character of Amelia is said to have been drawn for Fielding's second wife; and if, as has been alleged, he put her forbearance to tests of the same kind, it must also be confessed that he has in some degree repaid her by the picture which he has drawn

Fielding.

of her purity, delicacy, and tenderness. *Amelia* was published in 1751 by Millar, who paid a thousand pounds for the copyright, and contrived to reimburse himself by an ingenious stratagem which he practised on the trade. In 1752, Fielding, unmoved by former failures, commenced a literary newspaper and review, to be published twice a week, which he entitled the *Covent-Garden Journal;* but although his ready pen, sharp wit, and classical attainments, highly fitted him for conducting a work of this kind, it was his failing to embroil himself in the party squabbles or literary feuds of the day; and on this occasion it was not long ere he involved himself in a quarrel with Dr Hill and other periodical writers, amongst whom we regret to mention Smollett, a man possessed of kindred genius, and second only to Fielding in that department of literature where both so eminently excelled. The warfare was of short duration, and neither party would derive honour from an inquiry into the cause or the conduct of hostilities.

Meanwhile Fielding's strength was fast decaying; a complication of disorders having terminated in a dropsical habit, which totally undermined his naturally robust constitution. But as the Duke of Newcastle, then prime minister, was desirous of receiving assistance from him in the formation of a plan for the prevention of secret robberies, and for improving the police of the metropolis, Fielding undertook, for the small consideration of L.600, to be paid by government, to extirpate several gangs of daring ruffians, who then infested London and its vicinity; and, though his health was thus impaired, he continued to superintend the conduct of his agents, to take evidence, and to make out commitments, until this great object was accomplished. The exertions which were thus rendered necessary, however, proved fatal to his exhausted frame, which was now suffering under dropsy, jaundice, and asthma. The Bath waters were tried, but in vain; and various modes of cure or alleviation were resorted to, though with little effect. As a last resource, therefore, his medical advisers recommended him to try the effect of a milder climate; and with this view he undertook a voyage to Lisbon, of which he has left a record, written with a hand trembling almost in its latest hour.[1] Fielding, however, reached that city alive, and remained there two months; but he was unable to continue his proposed literary labours. The hand of death was upon him; and in the beginning of October 1754 he terminated his earthly career, in the forty-eighth year of his age, leaving behind him a widow and four children. "Thus lived, and thus died," says Sir Walter Scott, "at a period of life when the world might have expected continued delight from his matured powers, the celebrated Henry Fielding, father of the English novel, and in his powers of strong and national humour, and forcible yet national expression of character, unapproached as yet even by his successful followers." (See Murphy's *Life and Genius of Fielding;* Chalmers' *Biog. Dict.* art. *Fielding;* and, above all, Sir Walter Scott's *Prefatory Memoir,* in Ballantyne's *Novelist's Library.*) (A.)

FIERI FACIAS, in *Law*, a writ that lies where a person has recovered judgment for debt or damages in the king's court, by which the sheriff is commanded to levy the debt and damages on the defendant's goods and chattels.

FIESOLE, a city of the grand duchy of Tuscany, in Italy, in the province of Florence. It occupies an elevated situation, is the see of a bishop, and has a cathedral, several churches, and but few inhabitants. It is a place of great antiquity, having been in remote ages one of the twelve eminent cities of Etruria. It has now several country-seats of the Florentine nobles.

FIFESHIRE is situated between 56° 3′ and 56° 25′ north latitude, and bounded by the River and Frith of Tay on the north, by the German Ocean on the east, by the Frith of Forth on the south, and by parts of Kinross, Perth, and Clackmannan on the west. Its greatest length is about fifty miles, and its greatest breadth about twenty miles; but its medium length from east to west is only about thirty-six miles, and its breadth from north to south about fourteen miles. Its area, therefore, contains about 504 square miles, or 322,560 English acres.

The most prominent features in Fifeshire, when viewed at a distance from the south, are the two Lomond Hills, in the middle of the county, the westmost of which rises 1721 feet above the level of the sea; Largo Law, farther east, 952 feet; and Kelly Law, 810 feet. Besides these, there are numerous other elevations scattered throughout the county; and indeed it is everywhere found to present a pleasant variety of hill and valley, stretching in general from west to east, parallel to the Tay and the Forth. The principal valley is that through which the river Eden flows, and is called the Howe of Fife. It lies to the north of the Lomond range of hills, and divides the county into the northern and southern portions. The valleys of the Leven and the Ore, and the valleys connected with, or as it were opening into, the Howe of Fife, are of much smaller extent and appearance. The hills and country on the north of the Howe of Fife seem to be a continuation of the Ochil Hills, and have been considered by geologists as belonging to the old red sandstone formation. The prevailing rocks found there are red and white sandstone, amygdaloid, compact felspar, claystone, clinkstone, greenstone, basalt, traptuff, and wacké. Limestone is also found near Newburgh, and shell marl in abundance at Rossie and Lords Carnie.

The mineral structure of the Howe of Fife, and of some of the other valleys, has never yet been minutely explored. Sandstone quarries, however, have been opened at different places, and here and there are to be seen eminences of gravel regularly stratified. The rocks of the southern division of Fifeshire chiefly belong to the coal formation of geologists, and form a portion of the great coal field of the Forth. Here glance coal, or blind coal as it is sometimes called, is met with occasionally; and slate coal, pitch coal, and cannel coal, are occasionally found together in the same bed, and sometimes in separate strata in the same pit.

---

[1] Of his departure for Lisbon he has himself left the following melancholy record, in which his situation is painted a thousand times better than could have been done by any pen but his own: "On this day, Wednesday, June 26, 1754, the most melancholy sun I had ever beheld arose, and found me awake at my house at Fordhook. By the light of this sun, I was, in my own opinion, last to behold and take leave of some creatures on whom I doated with a mother-like fondness, guided by nature and passion, and uncured and unhardened by all the doctrine of that philosophical school, where I had learned to bear pains, and to despise death. In this situation, as I could not conquer nature, I submitted entirely to her, and she made as great a fool of me as she had ever done of any woman whatsoever; under pretence of giving me leave to enjoy, she drew me in to suffer, the company of my little ones during eight hours; and I doubt not whether, in that time, I did not undergo more than in all my distemper. At twelve precisely my coach was at the door, which was no sooner told me, than I kissed my children, and went into it with some little resolution. My wife, who behaved more like a heroine and philosopher, though at the same time the tenderest mother in the world, and my eldest daughter, followed me. Some friends went with us, others here took their leave; and I heard my behaviour applauded, with many murmurs and praises to which I well knew I had no title." (*Voyage to Lisbon*, p. 1.) This affecting passage remains a singular example of Fielding's natural strength of mind; and, indeed, the whole of the *Journey to Lisbon* shows that, whilst struggling at once with the depression and the irritability of disease, he could still exhibit a few flashes of that bright wit which used to set the world in a roar. "His perception of character, and power of describing it," says Sir Walter Scott, "had not forsaken him in those sad moments; for the master of the ship in which he sailed, the scolding landlady of the Isle of Wight, the military coxcomb who visits their vessel, are all portraits marked with the master-hand which traced Parson Adams and Squire Western."

From a charter dated in March 1291, it would appear that coal has been worked in this county for more than five centuries. William de Oberville there grants liberty to the convent of Dunfermline to open a coal-pit in his lands of Pityncreiff. But it has been alleged that this is not the first instance of a Scottish charter containing a right to work coal; for one dated 1284–85 is said to exist, from which it may be inferred that coal was worked in the lands of Tranent before that period. The principal coal works in the county at present are those in the parishes of Dunfermline, Dysart, Wemyss, and Markinch; but coal is also worked at present, or has been so formerly, in the parishes of Torryburn, Inverkeithing, Dalgety, Burntisland, Abbotshall, Auchterderran, Scoonie, Largo, and Pittenweem.

In the southern division of Fifeshire limestone is also abundant. The lime works at Charleston, belonging to the Earl of Elgin, are perhaps the greatest in Scotland. Upwards of 100,000 tons are said to be raised annually in his lordship's quarries; which quantity is either shipped or sold in its native state, or after being calcined. The Carron Company also work out extensively the lime on their estate of Newbigging, in the parish of Burntisland, and ship it at the harbour of Starleyburn, on the Forth, for their works at Carron, where it is used for smelting iron. The great iron work on the Devon is also supplied for a similar purpose with limestone from Whinnyhall, in the parish of Burntisland. The limestone in the interior of the county is likewise transported across the Howe of Fife, and by the way of Newburgh, to the Carse of Gowrie, and Forfarshire and Perthshire.

Sandstone abounds in the southern division of the county; and, in many places, it is of a fine grain and durable nature. The principal quarry in the county is at Cullello, in the parish of Aberdour. The stone obtained from it, in consequence of its superior quality, has been used for some of the finest buildings in Edinburgh, as well as carried over land to great distances. Ironstone also abounds in the coal field, and was once worked extensively at Balgonie, where it was smelted. But it is now chiefly worked at Dysart, and sold to the Carron Company. The other rocks found in this coal field are bituminous shale, slate clay, flinty slate, wacké, traptuff, amygdaloid, greenstone, and basalt. Stones somewhat resembling the precious garnet are sometimes found imbedded in the traptuff at Ely, and are known by the name of the Ely rubies. Copper and zinc are also said to have been met with in different places, and lead has been worked in the Lomond Hills. Marl is also often found in the marshes and in the lakes, and sometimes in dry seasons it is carried away for agricultural purposes.

There are none of the mineral springs in the county so remarkable as to be at present frequented as watering places. Those which arise in the coal fields are frequently chalybeate. One of the two mineral springs at Dysart yields a chalybeate water of considerable strength. In the Howe of Fife springs issuing from the sandstone or gravel are said to be frequently saline. But in the portions of the county where the trap-rocks abound, the springs, whatever virtues they are supposed to possess, seldom yield any thing but pure water. From the Inkcraig of Carnock, adjoining to a dam dike, there is said to issue a spring of petroleum, from which there constantly drops a liquid resembling ink.

The only streams of any note in the county are the Leven and the Eden. The former, which issues from Loch Leven, in Kinross-shire, flows eastward, through a beautiful strath, by Leslie, Balgonie, and Balfour, and, after a course of about twelve miles, during which it receives the Lothrie and the Orr, falls into the Frith of Forth at the town of Leven. From the declivity of its channel, it is well fitted for impelling machinery; and accordingly a great many mills and other works have been erected on its banks. An act of parliament was lately obtained, the chief object of which was the erection of works and the construction of mechanism, to regulate the rise or fall of the water in the lake, and to restrain or increase the flow of the river for the benefit of the bleachfields and other manufactories erected upon its banks; and these objects have been accomplished at a sum considerably exceeding L.30,000. The Leven abounds in salmon and sea trout, and where it falls into the sea there is a salmon fishery. The Eden is formed by the confluence of several small streams in the parish of Strathmiglo on the west, near the boundary of Fife with Kinross-shire, and winding slowly through the level valley, and sometimes overflowing its banks, passes the town of Cupar, and loses itself in the German Ocean about eighteen miles from its source. It contains trout, pike, and eels, and has also a salmon fishery where it discharges itself into the sea. The Guard Bridge over this river, consisting of six arches, was built in the beginning of the fifteenth century.

There are a number of lakes in the county, none of them very large, but some of them very beautiful, such as those at Lindores, Kilconquhar, Kinghorn, Lochgellie, Camilla, Lochfittie, and Otterston. Most of these lakes abound in pike, perch, and eels, and are frequented by ducks, coots, and other water fowl. The county once contained many more lakes, which have been drained at great expense. Amongst these, the most considerable are the lakes of Rossie and Lochore. Their beds are now used in raising valuable crops.

From the extensive drainage of the lakes, and the general improvement of the county, its climate within the last forty years has been considerably ameliorated, and is more free than formerly from the injurious fogs which used to arise from the lochs and damp lands. At present the climate may be described as mild. The harvests are early, and snow seldom lies long. As the direction of the hills in the county is from east to west, it is much exposed to the easterly winds, which often check vegetation in the spring months; and hoar frosts are not unfrequent so late as the middle of June. The heaviest rains are from the south-west, the south-east, and the north-east, and the winds from the two last points bring the heaviest falls of snow. The driest and most steady weather comes from the north-west and east.

Four fifths of the county at least are considered at present as arable, and the remainder consists of hills, marshes, moors, lands covered with drifted sand and chiefly bearing bent, extensive plantations, and high roads. Along the banks of the Forth, above the trap-rocks, and the tract of country on the north of the Howe of Fife, the soil is for the most part of excellent quality, being rich loam, good clay, and gravel mixed with loamy earth. The soil from St Andrews to the western parts of the county, where the strata underneath consist of freestone, coal, or slate, is in general greatly inferior. The Howe of Fife contains a considerable proportion of moor and moss, besides a tract of loam partly deep and moist, and partly light and dry.

Within the last forty years extensive woods have been planted in the county. For instance, there is a forest of Scotch firs in the Howe of Fife, stretching for many miles in length, on the Leven, Crawfurd, and other estates. Forests of all kinds of trees have also been planted on the Raith estate, by Mr Ferguson, the proprietor; and a princely ride along the Cullello Hills, of considerable length, was formed and adorned with plantation several years ago by Mr Stuart of Dunearn. Indeed there is hardly a proprietor in Fifeshire of the least consequence who has not contributed extensively to the creation of forests and pleasure grounds on his estate. The oldest woods in Fife are round Leslie House, the seat of the Earl of Rothes.

There are a great number of splendid mansions in the county belonging to the nobility and gentry, and situated upon their estates. There are some of these estates pretty large, and a greater number above L.500 Scotch of valuation than in any other county in Scotland. But of the 638 estates which it contained in 1811, 491 were below that amount. The annual value of the real property, as assessed in April 1815, amounted to L.405,770 sterling.

In the year 1811, the number of freeholders entitled to vote for a county member of parliament was only 207. In 1832, the roll of these voters last made up under the old law contained 234 names, and of this number sixty-three were considered as paper voters; that is, two or three were apparent heirs of owners who were on the roll, and the remainder of the sixty-three were merely nominal owners of the estates from which they derived their privilege. The number of voters for the county member at present on the roll, under the act 2 and 3 William IV. cap. 65, is 2228.

The average size of the farms in Fife used to be about 150 acres; few of them were what might be called large, the greater number were small. Of late years, however, the tendency has been to join several together under one tenant. Many of the farmers are now men of capital and enterprise; and under their direction, supported by the liberality of the proprietors, the recent extensive agricultural improvements, which are visible throughout every part of the county, have been undertaken. The most improved implements of husbandry are everywhere in use. Thrashing-mills are to be found on most farms, some of them moved by horses, a few by wind-mills, others by water-wheels, and of late a number by steam-engines, a power which seems to be in progress of superseding all others. The farm-steadings, and the dwellings of the peasantry, have in a great measure been renewed within the last thirty years, and much improved and enlarged; and the greater part of the fields in the county are well enclosed either with stone dikes or hedges.

All the farm crops common in the south of Scotland are cultivated here upon a large scale, and almost always according to the most approved system. Flax is now seldom raised. The crops commonly cultivated are, different kinds of oats, barley, wheat, rye, beans, peas, and tares; clover and ryegrass, potatoes, and turnips; and mangel worzel has in some places been recently introduced. Farm-yard dung, the cleanings of the streets of the many towns and villages, and the sea-weed cast ashore and cut upon the rocks, are the principal manures. Lime is universally used, and marl in a few places. Bone dust has also been tried within the last few years, and, upon the whole, very successfully.

Cattle of the Fife breed have long been in high repute both as fattening and dairy stock. The prevailing colour is black; limbs short and body round; horns small, white, and turned up at the points; bone small in proportion to the carcass; and weighing, when fat, and from three to four years old, from forty to sixty stone. The cows, when well fed, yield from ten to fourteen Scotch pints of milk daily during the best of the grass season, and continue long in milk; yet, except in the neighbourhood of the considerable towns, the dairy is considered as a secondary object. The oxen were formerly much employed in labour, but they are now seldom to be seen at work. Flocks of sheep are not very numerous. The horses are much the same as in all the lowlands of Scotland. A great many pigs have of late years been reared in the county, and many of them are killed and shipped in a fresh state for the London market. Pigeons are very numerous, the pigeon-houses being lately estimated at no less than 300. Rabbits are in some places protected; and hares, pheasants, and partridges are plentiful. There are few grouse or black-cock; and fallow deer have been frequently seen at Lochfittie, Torbain, and other places.

Grain is sold in stock and sample at various weekly markets in Fife, of which the most considerable are at Anstruther, Auchtermuchty, Kirkaldy, Largo, and Newburgh. There are also weekly markets at Dunfermline, Cupar, and other places, for the same purpose; and every town of any consequence has one or two yearly fairs for the sale of cattle, &c. although it must be admitted that the number of the yearly fairs in Fife has been much diminished.

The staple manufacture of this county is linen. Dunfermline has long been famous for its extensive and almost exclusive manufacture of damasks and diapers. Of late years, by the introduction of French improvements in the machinery, and the ingenuity of the workmen, the quality of the fabrics has been much improved, and the trade greatly enlarged. Ticks, checks, sail-cloth, dowlas, and other plain linens and sheetings of every quality, are made in several towns in the county, but the great seat of the manufacture is Kirkaldy. In 1812, no less than 4,500,000 yards of linen cloth were made by the manufacturers, and stamped of the value of L.280,000; and in 1800, about 600,000 yards of plain linen were supposed to have been made by private families for their own use, which were not stamped. The number of hands employed in all the branches of this manufacture in 1800 was computed at 23,192; but the number of hands now employed is greatly increased. No part of the work of weaving in this county is at present, however, carried on with the aid of steam power. There was one steam-loom factory lately in Kirkaldy, but it has been converted into a spinning mill.

Flax has seldom or never been spun by the hand since the introduction of spinning mills. These now amount to forty-five in number, and include in all upwards of 29,000 spindles. Of these, Mr Fergus of Strathore employs at present, in his great work at Prinlaws, 2684 spindles; and erections have been made at the same work for receiving about 3000 more. Messrs C. Arthur and Sons at Kinghorn run upwards of 2000; Nelson and Co. at Kirkland 1800; Mr John Rutherford, Dunfermline, 1376; Henry Balfour and Co. Leven, 1240; Arthur Aitken and Co. Dunfermline, 1066; W. & J. Yule, Ceres, 1048; Mr Swan, Kinghorn, 1026; Mr George Moon, Russel Mill, 1012; but the various other mills have less than 1000 spindles each at work. Supposing each spindle to spin half a spyndle daily, making suitable allowances for stoppages and holidays, the various mills in Fife will spin 13,000 spyndles daily, 78,000 per week, or 3,900,000 per mill-spinner's year of fifty weeks; producing yarn to the value of L.438,750, and consuming 6500 tons of flax. The persons employed at these mills consist of hecklers, male and female preparers, spinners, reelers, &c.; and allowing one individual for each twelve spindles, there will be employed at the spinning mills in Fife, of all ages and in all the departments, about 2240 people. Messrs Nelson and Company, at the Kirkland works, manufacture a large proportion of their yarns into sail-cloth and other fabrics; and Mr Rutherford, Dunfermline, converts the greater part of his yarns into threads of all colours. The yarns at the other mills are generally sold as they are spun.

Besides the trades and manufactures of the county may be mentioned ship-building, which is carried on at Dysart, where there is a wet dock, and a Morton's slip for raising the vessels out of the water for repair; and at Burntisland, where there is a good harbour and dry dock; as also at Kirkaldy, Anstruther, and Scotscraig. There are, besides, in the county, forty-eight brewers of ale and beer, the greater part of whom also make malt; fifty-six other maltsters, six extensive distilleries, 1140 retailers of ale and spirits, about 200 retailers of foreign wines, twenty-two dealers in vinegar, 900 dealers in tea, ten manufacturers of tobacco, and about 800 dealers in that article; one soap work and eighteen tallow chandlers; two paper-mills on the water of Leven, and nine bleachfields on the same stream, four in the neighbourhood of Kirkaldy, and six in other parts of the county; ten brick and tile manufactories, and two potteries; four iron founderies, numerous smiths and wrights, ten works for tanning leather, about as many curriers, two skinners, and two glue manufacturers.

The shipping of the county is pretty extensive, and the vessels belonging to it are of such burden as to trade to all parts of the world; a number of them being engaged in the whale fisheries, and others in the Baltic, American, and Australian trade. The exports are the manufactures already mentioned, and the produce of the whale fisheries, coal, limestone, lime, potatoes, and grain of all sorts; and the imports from foreign parts are timber, bark, hides, tallow, flax, hemp, tar, iron, &c.; and coastwise, pavement and slates, groceries, and other articles required for home consumption. For the state of the harbours and the extent of their trade, see the articles FORTH and TAY.

The banking business of the county is extensive. It is managed by branches of the Bank of Scotland at Dunfermline, Kirkaldy, and St Andrews; of the Commercial Bank of Scotland at Cupar, Colinsburgh, Dunfermline, and Kirkaldy; of the National Bank of Scotland and of the Glasgow Bank at Kirkaldy; and of the British Linen Company at Cupar.

Fifeshire contains thirteen royal burghs with parliamentary privileges. St Andrews, Cupar, Anstruther Easter, Pittenweem, Crail, Kilrenny, and Anstruther Wester, with a constituency at present of 635, send one member to parliament; Kirkaldy, Dysart, Burntisland, and Kinghorn, with a constituency of 415, send another; and Dunfermline, having a constituency of 500, and Inverkeithing of thirty-eight, join with Stirling, Queensferry, and Culross in electing a member to represent them. The voters in these thirteen Fife burghs have now increased their constituency to 1588, instead of the 304 individuals who formerly composed their corporations.

The courts in the county for the trial of crime and civil suits consist, 1*st*, of the burgh courts, the magistrates of which have jurisdiction within their respective royalties or burgh territory only; 2*dly*, of the sheriff courts, for similar purposes, which are held at Dunfermline for the parishes in that presbytery, and at Cupar for the other parts of the county, at each of which towns the cases are tried either by the sheriff in person, or by substitutes, of whom he has for the purpose one constantly resident at Cupar, and another at Dunfermline, he himself being usually resident in Edinburgh; 3*dly*, of the justice of peace courts, which are held periodically at Cupar, Auchtermuchty, Anstruther, Colinsburgh, Kirkaldy, and Dunfermline, for trying actions of debt under five pounds, and petty criminal matters.

The principal jails in the county are at Dunfermline, Kirkaldy, Cupar, and St Andrews. There is also a small jail attached to the town-hall of almost every burgh in the county, but many of these are seldom used for the reception of prisoners. With the exception of the jails of Cupar, Kirkaldy, and Kinghorn, which are the best in the county, having been erected within the last twenty-five years, none of them have airing ground attached to them for the use of the prisoners, or are well fitted as places of confinement.

The great turnpike-roads of the county, which are made and maintained by the revenue of the toll-bars, and the bye-roads, which are maintained by a tax on householders, on carriages, and on each plough-gate of land, are under the charge of parliamentary trustees, consisting chiefly of the justices of the peace, and commissioners of supply for the county. Each of the four presbyteries forms a district for managing its own roads. The accounts of the turnpike trustees are printed and published annually. The accounts of the bye-road trusts have however not yet been published. The turnpike-roads and many of the bye-roads are in excellent order, great attention being paid to the introduction of the most recent improvements in road-making. Private railways of wood or iron have been used for many years in transporting for several miles the produce of the coal and lime quarries to the harbours where they are shipped. The most extensive of these railroads is that belonging to the Earl of Elgin. It proceeds from near Dunfermline to Charleston harbour, and has been lately opened to the public for the use of rail coaches carrying passengers.

Fifeshire is divided into sixty-one parishes, belonging to the four presbyteries of St Andrews, Cupar, Kirkaldy, and Dunfermline, which compose the synod of Fife; but there are four parishes besides in the presbytery of Dunfermline, and one in the presbytery of Kirkaldy, which are not situated in this county.

The population of Fifeshire in 1801 was 93,743; in 1811, 101,272, an increase of eight per cent.; in 1821, 114,550, an increase of thirteen per cent.; and in 1831, 128,800, an increase above the preceding census of twelve per cent.

FIG, or FIG-TREE. See FICUS.

FIGEAC, an arrondissement of the department of the Lot, in France, extending over 672 square miles. It is divided into eight cantons and 168 communes, containing 80,178 inhabitants. The capital is a city of the same name, situated on the river Celle, where there is some trade in corn and in wine. There are in it 1300 houses and 6452 inhabitants. Long. 1. 55. E. Lat. 44. 40. N.

FIGUERAS, a town and fortress of Spain, in the province of Catalonia, and one of the most important of its defences on the eastern frontiers of France. It is strongly fortified, and situated in the fruitful district of Ampurdan, abounding in fruits and grain, being watered by the river Fluvia, which, though usually fordable, becomes an extensive river when swollen with rain, or with the melting of the snow on the mountain whence it springs. It is in north latitude 43. 16. 1. and east longitude 3. 29. 15. from London. The fortress is capable of containing a garrison of from 12,000 to 16,000 men. The inhabitants of the town are reckoned at 4640.

FIGURAL, FIGURATE, or *Figurative*, a term applied to whatever is expressed by obscure resemblances.

FIGURE, in *Physics*, expresses the surface or terminating extremities of any body. Figures, in *Arithmetic*, are certain characters by which we denote any number which may be expressed by any combination of the nine digits. Figure, amongst divines, is used to signify the mysteries represented under certain types. Figure, in *Dancing*, denotes the several steps which the dancer makes as marking certain figures on the floor. Figure, in *Painting* and *Designing*, denotes the lines and colours which form the representation of any animal, but more particularly of the human form. Figure, in *Logic*, denotes a certain order and disposition of the middle term in any syllogism. (See LOGIC.)

FIGURE *of Speech* is defined the using a word in a sense different from what is proper to it; and the new or uncommon sense of the word is termed *the figurative sense*. Figure, in *Theology*, is used for the mysteries represented or delivered obscurely to us under certain types or actions, in the Old Testament.

FIGURE OF THE EARTH.

SECTION I.

INTRODUCTION.

The determination of the figure and dimensions of the earth is a problem of very great importance in astronomy, inasmuch as it is in reference to the earth's diameter that the distances of the planets from the sun and from each other are estimated. It is also a problem of very great interest and curiosity; and has accordingly attracted the attention of mankind since the earliest dawn of civilization.

There are two points of view under which this great question may be considered. The figure of the earth may be regarded as a fact to be determined by investigation and experience, like any other phenomenon or law of nature; in which case it is necessary to find, by the actual measurement and comparison of different portions of the terrestrial surface, the nature of its curvature, and the magnitude of its diameters. Under the second point of view, the question is one of pure theory. The earth may be regarded as a congeries of material particles, attracting each other with forces reciprocally proportional to their mutual distances, and endowed with a rotatory motion about a fixed axis; and the problem is to determine the form the whole mass would assume in virtue of the attractive and centrifugal forces by which the particles are impelled. Viewed in this light, the actual figure of the earth becomes one of the series of consequences resulting from the universal gravitation of matter, and depending on the same laws which regulate its motion in its orbit about the sun.

It would be a waste of time to inquire what were the notions of the figure of the earth which were or might have been entertained by its earliest and most ignorant inhabitants. A very slight attention to the most common phenomena renders the fact of its general roundness almost palpable to the senses. The uniform level appearance of the sensible horizon in every situation in which a spectator can be placed,—the depression of the circumpolar stars as he advances toward the south, and their elevation as he proceeds in a contrary direction,—the disappearance of a ship standing out to sea,—the projection of the earth as seen in a lunar eclipse,—and a number of other familiar appearances,—put the globular figure of our planet beyond all manner of doubt. Reasoning from such appearances, the earliest astronomers universally regarded the earth as a sphere; and their attention was solely directed, in their various measurements and computations, to ascertain its dimensions. Modern science has discovered that its figure deviates slightly from that of a sphere, being compressed or flattened at the extremities of its axis of rotation; and the object of the astronomer, at the present time, is to determine not only its dimensions, but also the exact amount of its compression.

Attempts to estimate the magnitude of the earth were made at a very early date; for Aristotle relates that the mathematicians prior to his time had found the circumference to be 400,000 stadia. But Eratosthenes appears to have been the first who entertained an accurate idea of the principles on which the determination of the figure of the earth really depends, and attempted to reduce these principles to practice. His results, in consequence of the imperfect data from which they were deduced, were very inaccurate; but his method is the same as that which is followed at the present day, depending, in fact, on the comparison of a line actually measured on the surface of the earth with the corresponding celestial arc. He had remarked, or been informed, that at Syene in Upper Egypt, on the day of the summer solstice, at noon, objects cast no shadows; whence he concluded that the sun was exactly in the zenith at mid-day. On the same day at Alexandria he observed the sun's meridional distance from the zenith to be 7° 12′, or a fiftieth part of the circumference. Then, assuming Syene to be exactly under the meridian of Alexandria (the error in this assumption was about 3°), and the distance between the two places, measured in a straight line, to be 5000 stadia, he had $5000 \times 50 = 250{,}000$ stadia for the whole circumference of the earth. It is easy to see how very imperfect this operation must have been. Without mentioning smaller errors, the neglect of the solar diameter would alone occasion an uncertainty as to the sun's declination, and consequently as to the length of the celestial arc, amounting to half a degree on the observation at Syene; and there is no reason to suppose that that at Alexandria was more exact. The terrestrial distance between the two places was assumed on equally, or probably still more loose and inaccurate determinations.

The next attempt to ascertain the dimensions of the earth was made by Posidonius. This astronomer adopted a method which differed from that of Eratosthenes only in determining the celestial arc by means of the altitude of a star, instead of the sun's zenith distance. At Rhodes the bright star Canopus, when on the meridian, barely appears above the horizon. At Alexandria the same star was observed to have a meridional altitude of a quarter of a sign, or seven and a half degrees, which, therefore, was the celestial arc intercepted between the zenith of Alexandria and Rhodes. The terrestrial distance between the two places was estimated, like that between Alexandria and Syene, at 5000 stadia, and they were both supposed to be under the same meridian. Hence, since seven and a half degrees is the forty-eighth of the circumference, we have $5000 \times 48 = 240{,}000$ stadia, for the whole circumference of the globe.

It is impossible to form any correct opinion of the degree of approximation attained in these ancient measures, as the length of the stadium is not known with any certainty. That it varied in different places, and at different times, is sufficiently obvious from the statement of Ptolemy, who, in his work on geography, assigns the length of the degree at 500 stadia, and consequently the whole circumference at 180,000, differing from the determination of Posidonius in the proportion of three to four, and still more from that of Eratosthenes. Ptolemy remarked that it was not necessary that the line measured should lie exactly in the meridian: it was sufficient to know its inclination to the meridian, or the azimuthal angle, together with the latitudes of its extreme points, in order to compare it with the meridional arc. The determination of the azimuth is, however, an operation of considerable difficulty; and Ptolemy has given no details of the method by which he proposed to estimate it. He has been equally silent in respect of the means by which the mean length of a degree was ascertained to be 500 stadia, so that the result which he has recorded is still less satisfactory than those of the two more ancient astronomers.

The active curiosity of the Arabians, which was exerted so successfully in promoting practical astronomy, did not overlook the measure of the earth. The Caliph Almamoun, who began his reign in the year 814, ordered a company of astronomers to measure a degree on the level plain of Mesopotamia. Dividing themselves into two parties, the one proceeded northward, and the other southward, in the direction of the meridian, through a degree of latitude, and measured with rods the itinerary distance as they proceeded. The perfect agreement of their conclusion with that of Ptolemy throws it open to great suspicion; and when it is considered that their operation was repeated at a different place, with exactly the same result, there can be no doubt that they blindly adopted the statement of the Greek astronomer, either from inability to execute the task assigned to them, or because they had no confidence in their own determination.

From the time of Almamoun, the problem of determining the dimensions of the earth was neglected, till the revival of astronomy with general learning in Europe. The first attempt to solve it was made by Fernel, who, about the middle of the sixteenth century, measured the distance from Paris to Amiens along the high road, by observing the number of revolutions made by his coach-wheel in the journey between these two cities. Supposing them to be under the same meridian, which is nearly true, and having ascertained the difference of their latitudes, Fernel found by this means the length of the degree to be 57,070 French toises, or about 364,960 English feet. A degree was measured long afterwards at the same place by Lacaille, in a far more adequate and scientific manner, and he found it to be 57,074 toises. This agreement is rendered less extraordinary by the circumstance that the toise of Fernel was not exactly of the same length as that of Lacaille. After all, it must be allowed that Fernel made a fortunate guess. (Delambre, *Astronomie,* tom. iii. chap. xxxv.)

But the first who had the merit of attempting to execute the geodetic operations that are indispensably necessary to effect the accurate measurement of a long line on the surface of the earth, was Willebrord Snell, a native of Holland, and a teacher of mathematics. Having established a chain of triangles between Alkmaer and Bergen-op-Zoom, and observed the angles of each triangle by means of a quadrant of five and a half feet radius, he measured a base on the frozen surface of the meadows between Leyden and the village of Soeterwoud, and determined the distance between the two places by trigonometrical computation. The length of the degree which he found was 28,500 Rynland feet, or about 55,020 toises, which is about 2050 toises too small. This result was published by Muschenbroek, who in fact revised or calculated the observations from the original papers a century after the death of Snell.

Norwood in the year 1635 attempted to measure a degree in England nearly in the same manner as Fernel. He measured the distance between London and York along the public road, taking the bearings and reducing the direction to the meridian in a rough way. The difference of latitudes he found by observations of the solstice to be 2° 28′, and thence concluded the length of the degree to be 367,176 English feet. Like the measurement of Fernel, this has been found to be a much nearer approximation than the method employed would have led us to expect.

The application of the telescope to circular instruments gave a far higher degree of precision to geodetic operations. Picard, to whom practical astronomy is indebted for this capital improvement, was the first who measured an arc of the meridian with such precautions and care as the delicate nature of the operation requires. With a standard scale he measured a base of about six English miles in length; and observed the angles of his triangles with a quadrant, having a telescope adapted to it with cross wires in its focus. He even calculated the error produced by the instrument being placed out of the centre of the station, and determined the zenith distance of a star in the constellation Cassiopeia with a sector, for the purpose of obtaining the differences of latitude. The distance between Amiens and Malvoisine was found to be 78,850 toises, and the difference of latitude 1° 22′ 55″, whence the result gave for the degree at Amiens 57,060 toises; but as the aberration and nutation were unknown at that time, and the refraction was not taken into account,—causes of error to which it is indispensably necessary to have regard,—a determination which agrees so nearly with the results of recent measures could only have arisen from a fortunate compensation of errors. In fact, his toise was somewhat shorter than that which has since been adopted as the standard; and the error occasioned by this circumstance nearly compensated that which was committed in determining the celestial arc, so that in recalculating all the observations, the degree is found to be very nearly the same as was found by Picard.

Hitherto geodetic operations had been confined to the determination of the magnitude of the earth; but a discovery made by Richer turned the attention of mathematicians to its deviation from the spherical form. This astronomer having been sent, by the Academy of Sciences of Paris, to the island of Cayenne in South America, for the purpose of determining the amount of terrestrial refraction, and other astronomical objects, observed that his clock, which had been regulated at Paris to beat seconds, lost about two minutes and a half daily at Cayenne, and that, in order to bring it to measure mean solar time, it was necessary to shorten the pendulum by more than a line. This fact, which appeared exceedingly curious, and was scarcely credited till it had been confirmed by the subsequent observations of Varin and Deshayes, was first explained in the third book of the Principia, by Newton, who showed that it could only be referred to a diminution of gravity arising from one of two causes—a protuberance of the equatorial parts of the earth, and consequent increase of the distance from the centre, or from the counteracting effect of the centrifugal force, occasioned by the rotation of the earth. The former could not, on any reasonable supposition regarding the figure of the earth, be regarded as adequate to produce the effect; but the latter, which would produce a retardation of the pendulum at Cayenne in the ratio of the square of the sine of 6° to that of 49° (the respective latitudes of Cayenne and Paris), might amount to 1·46 seconds. This was the first direct proof that had been obtained of the diurnal rotation of the earth.

From this time the exact determination of the figure of the earth began to assume a degree of importance which had not formerly attached to it. The centrifugal force arising from the diurnal rotation completely set aside the idea of perfect sphericity. Newton, assuming that the earth had been originally fluid, and supposing its density to be the same throughout the whole mass, and supposing moreover that its constituent molecules attract one another in proportion to the inverse square of the distance, demonstrated that it would assume, in consequence of the rotation, the form of a spheroid flattened at the poles; and that the proportion of its equatorial to its polar axis would be 230 to 231. But the supposition of the equal density of the earth is obviously very improbable, and consequently the ratio of the equatorial and polar diameters must be different from that now mentioned. Newton erroneously concluded that if the density is greater in the interior of the earth than at the centre, the compression would be greater than in the case of a spheroid of equal density. This mistake was pointed out by Huygens, who, in order to determine the amount of the compression from theory, reasoned in this way. Suppose two tubes to be united at the centre of the earth, forming a right angle with each other at that point, and extending to the surface, one in the plane of the equator, and the other along the polar axis, and filled with a homogeneous fluid. Now the fluid contained in the polar branch exerts a pressure on the centre equal to the whole of its weight, while the pressure of that in the other tube will be diminished by the centrifugal force. The second column, therefore, if of the same length, will be less heavy than the first; and in order to restore the equilibrium, it is necessary that the equatorial tube shall have gained as much in length as it has lost in weight through the effect of rotation. Hence the sea in the equatorial regions must be higher, or at a greater distance from the centre, than the polar sea, and consequently the earth must have a flattened form. Calculating from the supposition that the density increases regularly from the surface to the centre, where it is infinite, Huygens found the ratio of the diameters to be that of 578 to 579. This investigation is given in his work *De Causa Gravitatis*, published in 1690.
